

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

ADDRESSES AND ORIGINAL ARTICLES

THE THERAPEUTIC ACTION OF IRON

By L. J. WITTS, M.D. Manch., F.R.C.P. Lond.

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON AT ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL

IRON is present in the food in the simple form of soluble iron salts and compounds of iron hydroxide with protein, and also in the complex form of hæmin derivatives—hæmoglobin, cytochrome, and other respiratory ferments of a porphyrin structure. Feeding experiments on animals indicate that only about half the iron in the food can be assimilated. The available iron of the food seems to correspond closely with the simple forms of iron, which can be estimated by chemical reactions such as Hill's dipyrindil method. Hæmin derivatives do not give these reactions, and they appear to escape absorption in the alimentary tract. Practically all of the iron of simple inorganic salts is available, and preparations such as ferric chloride, when accompanied by traces of copper, can be used as the sole source of iron in the diet of experimental animals. It appears that all compounds of iron must be broken down into simple salts before the iron can be assimilated, and that the hæmin compounds resist this process, so that their iron is not available to the organism.¹³

Iron is absorbed chiefly in the duodenum but the stomach and the whole of the small intestine may take part in the process. The upper part of the alimentary tract is an all-important area in hæmopoiesis and the surgeon should avoid too ruthless an exploitation of this territory. The body of the stomach secretes pepsin and the powerful mineral acid, hydrochloric acid, which is the solvent for the available iron of the food. So abundant is the gastric secretion in health that it more than suffices to neutralise the alkaline juices of the liver, the pancreas, and the intestine, and the reaction of the whole of the small intestine is acid. The pyloric portion of the stomach and the upper duodenum secrete a ferment which reacts with an extrinsic factor in the food to produce the liver principle. The duodenum is the chief site of iron absorption. The available iron of the food is probably reduced to the bivalent ferrous state in the alimentary tract, and after absorption it is either stored or transported to those places where it is required for its catalytic action and for the building of hæmoglobin. Iron is taken up by the nuclei of the erythroblasts, which elaborate hæmoglobin from it and are extruded from the ripening cell when their task is completed. Iron is also taken up by the other cells of the organism for the manufacture of cytochrome and other respiratory ferments. However administered, iron is excreted by the cæcum and large intestine, and little appears in the urine even when iron is introduced parenterally (Fig. 1).

We might expect to find that in health the absorption of iron by the stomach and small intestine would be equalised by the loss through the colon. Whether there is such an equilibrium, and, if so, how it is adjusted, are matters on which at present we have no trustworthy information. The administration of iron to normal animals and men does not affect the blood count, but much of the iron may be retained in the body. Absorption is proved by the rise in the serum iron, by the toxic effects of high dosage of iron in animals, by the investigation

of patients with ileal fistulæ, and by balance experiments. The estimation of iron in animal tissues and excretions is so difficult and the results of analyses of standard biological materials such as milk and serum are so divergent, that we can place no great reliance on the records of balance experiments. Lintzel, experimenting on healthy individuals, concluded that not more than 17 mg. of iron was retained,

FIG. 1.—The hæmopoietic Area of the alimentary tract.

however large a single dose was given. He assumed that there was an intestinal barrier to the absorption of iron, and stated that there was no advantage in prescribing more than 50 to 100 mg. of iron a day. His results are at variance with experience in the treatment of anæmia, for the hæmoglobin increment may correspond with a utilisation of 50 mg. or more of iron a day, and maximum improvement may not occur until large doses of iron are given. Moreover, Reimann and Fritsch gave patients with anæmia 100 mg. of iron a day and found that approximately 50 mg. a day was retained; only about 20 mg. a day could be attributed to the manufacture of hæmoglobin and the remaining 30 mg. were stored in the body. At the 1935 meeting of the Association of Physicians J. F. Brock reported iron retention of this order occurring for many weeks in patients receiving large doses of iron, so that a subsequent speaker was constrained to say that the patients must be converted into pillars of iron. If these results are confirmed we must believe that patients treated with iron store the metal, in amounts as large or larger than those found in hæmochromatosis, without developing siderosis of the organs; and as anæmic patients treated with large doses of iron may quickly relapse on omitting iron, we must believe that the iron they have sequestered (? in the bones) is a frozen credit which they cannot liquefy. Hæmochromatosis, on the other hand, is probably the result of an inborn error of metabolism which affects the disposal of endogenous and not exogenous iron.⁴⁰

Two other curious facts may also be mentioned. The first is described by Schulten as the "threshold phenomenon." We may, for example, treat a patient for many weeks with a daily dose of 30 grains of iron and ammonium citrate with no apparent effect; on raising the dose to 60 grains of iron and ammonium citrate a day there is a reticulocyte crisis and the anæmia is steadily repaired. Thus there is a minimal effective dose of iron. In other patients who are treated with a suboptimal dose of iron (which is

far larger than any diet could supply) the anæmia may improve for a few weeks and then become stationary at a higher but still subnormal level. In both these conditions it is difficult to explain why the anæmia does not slowly but steadily improve.

Iron Requirement

The professional fasting men, Cetti and Breithaupt, excreted about 10 mg. of iron a day during their periods of starvation, but the excretion of iron is abnormal during fasting owing to tissue breakdown. Lintzel showed that adult males can be balanced on a diet containing less than 1 mg. of iron a day, but much more iron is needed by the growing child and by the female during her reproductive life. The iron requirement in childhood has been estimated at 0.76 mg. per 100 calories of food ingested.⁴ In the female the reproductive function imposes an extra strain on the iron metabolism. Normally about four ounces of blood are lost at each period, or 50 mg. of iron, but in menorrhagia as much as 200 mg. may be lost.⁷ During pregnancy a total of 0.9 gramme of iron must be supplied from the food or the body reserves, or an average daily storage of 3.2 mg.⁸ Under fairly ideal conditions of diet and well-being, it seems possible for the maternal organism to assimilate enough iron for this purpose, assuming that the diet contains 15 to 20 mg. of iron a day, that half of this iron is "available," and that half of the available iron is absorbed. During lactation from 1 to 1.5 mg. of iron a day are secreted in the milk. Reproduction is a test not only of the maternal constitution but also of the standard of living, and a large section of the British community comes through the test badly. Davidson and co-workers have shown that diets averaging 11 mg. of iron a day, such as are taken by the poor in the Aberdeen area, are insufficient to maintain iron equilibrium in females who have begun to menstruate.

In addition to the physiological states which increase the requirement of iron, there are pathological conditions which impair its absorption and give rise to a "conditioned deficiency." The most important is achlorhydria. Impairment of the gastric secretion is found in a high proportion of cases of nutritional anæmia in infancy and childhood,^{1 18} idiopathic hypochromic anæmia,¹⁷ and hypochromic anæmia of pregnancy.⁴⁴ A diet high in iron usually has little demonstrable effect on simple achlorhydric anæmia, but if the food is predigested with hydrochloric acid and pepsin there may be a favourable response.^{2 9 26} The optimum dosage of ferrum redactum and of iron and ammonium citrate is higher in patients with achlorhydria than in those with normal gastric secretions.^{3 19 30 35 39 47} The most intractable examples of anæmia occur in patients in whom the gastric secretion has been reduced and the hæmopoietic area of the stomach and duodenum has been side-tracked by gastrectomy or gastroenterostomy. These cases seem to depend not so much on an acidity—in many of them the secretion of acid persists in spite of operation—as on a hurried passage through the jejunum, and they are associated with severe general impairment of the digestive powers and consequent modifications of the diet.¹⁶ In fatty diarrhœa also the action of iron is much diminished.

Potentialion and Antagonisation of Iron

The therapeutic action of iron can be enhanced by certain procedures which facilitate the absorption or the utilisation of iron. Bethell and co-workers showed that a dosage of 300 mg. a day of ferrum

redactum was ineffective when given in three divided doses of 100 mg. but was effective when given in ten divided doses of 30 mg.; this seems to be a pure absorption phenomenon. In experimental animals iron can be absorbed and stored in the liver but cannot be converted into hæmoglobin unless copper is also present³⁷; this is apparently a pure utilisation phenomenon. It is difficult to demonstrate the action of copper in man, in whom deficiency of copper is excessively rare. Pyrrole derivatives such as bile pigment,³⁴ chlorophyll, and the cytochrome of yeast^{32 33} potentiate the action of iron, probably by facilitating its conversion into hæmoglobin. Other examples of potentiation are more complex. The beneficial effect of the simultaneous ingestion of acid, in the form of hydrochloric acid or of buffered acid media,³⁷ is most simply demonstrated in patients with achlorhydria, in whom the acid acts by replacing the gastric secretion and facilitating absorption, but there is also evidence to suggest that iron is conserved in the body by an acid diet and that its excretion is increased by an alkaline diet.³⁶ The potentiating action of liver is highly complex, as liver is an acid food and a source of additional iron, copper, and pyrrole derivatives.³¹ Calcium is said to have an iron-sparing action,^{40 42 45} by which one must suppose promotion of absorption is meant, but the evidence is scanty, and in experiments on animals the reverse effect has been observed, rats becoming extremely anæmic on a high calcium diet.⁴¹ Apart from this last observation, which is of doubtful human application, the only example of antagonism to iron I have met is Lintzel's statement that citric, tartaric, lactic, and similar acids diminish the absorption of iron, on which account he believes that large amounts of fruit, such as apples, oranges, and lemons, should be forbidden in anæmia. The potentiation of iron must always be borne in mind in experiments designed to estimate the effective dosage of preparations. It is of little immediate therapeutic importance, as these adjuvant actions can only be demonstrated when suboptimal amounts of iron are given, and with rare exceptions hypochromic anæmia in man can always be repaired by massive doses of iron. On the other hand, the potentiation of iron is of the utmost importance to nutrition, because foods rich in available iron, such as meat and eggs, are costly, and diets should therefore be designed to ensure the utmost utilisation of the iron they contain. This is a direction in which we may look forward to further acquisitions of knowledge.

Dosage of Different Preparations of Iron

So far I have spoken of the therapeutic action of iron without making distinctions, but I hope to show that the various preparations of iron differ in therapeutic efficiency just as much as one star differs from another in brightness. One of our chief preoccupations in the study of anæmia has been the determination of the most suitable preparations of iron to be prescribed and the optimum dosage. It will be apparent from what has already been said that the assessment of the therapeutic action of iron requires carefully controlled conditions. Man is the most suitable animal for such experiments, not merely because of his large size or the facility with which his blood may be examined and his excreta collected, nor because his benefit is our ultimate goal. Indeed a study of the literature suggests that governments are more interested in preventing iron deficiency in their domestic animals than in their human populations. But man is peculiarly liable to suffer from a pure

and uncomplicated iron deficiency which can be completely corrected by the administration of inorganic salts of iron. In this country work on nutritional anæmia of infancy and idiopathic hypochromic anæmia was considerably influenced by McGowan's observations on iron deficiency in sucklings and sheep. With this notable exception work on animals has rarely been capable of immediate transfer to man. The original denial of the value of inorganic salts of iron; the subsequent equalisation of all inorganic salts of iron; the recommendation of whole liver and secondary liver extract in hypochromic anæmia; the emphasis on the action of copper—none of these has been directly applicable to man.

Iron is administered internally in medicine for its hæmatinic action and for its tonic or roborant action. My further remarks will be confined to its action in anæmia, though the presence of iron in every living cell suggests that its use in debility and in disease of the central nervous system is not without a theoretical basis. In the anæmias which respond to iron the red cells are paler and usually smaller than normal. Certain anæmias of this type, when left untreated, may persist almost unchanged for years. They respond dramatically to iron and are therefore an ideal subject for experiment. The most important examples are idiopathic hypochromic anæmia, with which I include chlorosis, and the anæmia of hook-worm disease. Certain chronic hæmorrhagic anæmias may also exhaust the ability to improve spontaneously and be suitable test-objects provided further hæmorrhage can be excluded. The criteria on which we select patients for experiment on the action of iron are as follows:—

1. The anæmia should be one of the torpid and hypochromic anæmias which I have mentioned.

2. Patients who have suffered from hæmorrhage or have recently been treated are unsuitable unless an adequate control period has shown no tendency to improve.

3. Infection, toxæmia, malignant disease, pregnancy, old age, and damage to vital organs such as the liver, the kidneys, and the thyroid, all impair the response to iron and render the case unsuitable.

4. The initial hæmoglobin level should not exceed 50 per cent., or else the reticulocyte response will be too small to be utilised and the hæmoglobin gain will not be comparable with that of the severer grades of anæmia.

5. The state of the gastric secretion should be known. Achlorhydria should not exclude the patient and is in fact an advantage, as anæmia is so often complicated by achlorhydria. Short-circuiting operations and severe functional disturbances of the alimentary tract such as steatorrhœa render the patient unsuitable.

6. The diet and mode of life should be constant throughout the period of observation.

In the pharmacopœia of the future the dosage of drugs will doubtless be given per kilogramme of body-weight and by mathematical formulæ or diagrams which express individual variations in therapeutic, toxic, and lethal reaction. At present there is neither the knowledge to compile nor the ability to use such a formulary, but it is well to remember that the customary method of stating doses gives little indication of the infinite variety of mankind in its response to medication. Some women with simple achlorhydric anæmia improve rapidly on as little as 15 grains of iron and ammonium citrate a day, others may need 150 grains. I shall therefore speak only of the average effective dose. The "single reticulocyte crisis" is not very helpful in determining average effective doses of preparations of iron, as the reticulocytoses in hypochromic anæmia are of a lower order and less constant than those of

pernicious anæmia.^{20 30} I will refer to the use of the "double reticulocyte response" later. Most use has been made of the "rate of hæmoglobin increase." The curve representing the rise of hæmoglobin during treatment has a sigmoid shape, there being an initial lag, a subsequent steady rise, and a final slowing in the rate of hæmoglobin regeneration as the normal level is approached. The maximum effect of treatment occurs between the second and fourth weeks, and the increase of hæmoglobin should therefore be estimated over a period of not less than 25 and not more than 40 days from the initiation of treatment.¹⁵ It has been found by experience that the rate of hæmoglobin regeneration in man rarely exceeds 2 per cent. a day. The "average effective dose" of a preparation of iron may be defined as the dose which produces an average increase of over 1 per cent. of hæmoglobin a day in a sufficiently large sample of patients with achlorhydria and anæmia, when the initial hæmoglobin level does not exceed 50 per cent., and when the period of observation is not less than 25 and not more than 40 days. The analyses of Heath and Fullerton show that about 60 per cent. of such a series of patients will gain more and 40 per cent. will gain less than 1 per cent. of hæmoglobin a day, but the mode of the series will be just over 1 per cent. In the accompanying Table I have summarised from my own experience and from the literature the average effective daily dose of the common preparations of iron.

TABLE showing average effective dose of common preparations of iron, and percentage of iron administered utilised for hæmoglobin formation.

Preparation.	Daily dose in grammes or c.cm.	Iron content in mg.	Utilisation (per cent.).
Metallic—			
Ferrum redactum ^{3 33 33}	1.5 to 6.0	1200 to 5000	0.5 to 2.0
Ferrous—			
Ferrous chloride ^{10 35}	0.25 to 0.5	100 to 200	12.5 to 25
Ferrous sulphate exsic. ¹⁵	0.6	180	14
Ferrous lactate ²⁸ ..	1.5	300	8
Pil. ferri carb. (Blaud) ^{30 31 47}	3.0 to 4.0	300 to 400	6 to 8
Ferric—			
Liq. ferri perchlor. ..	8.0	400	6
Ferric citrate ³⁵ ..	2.0	400	6
Iodoan (ferric hydrox.) ²⁹	30 to 45	1500 to 2250	1.1 to 1.7
Soluble ferric oxide ³⁵	35	1000	2.5
Complex ferric—			
Fe et ammon. cit. ^{31 47}	4.0 to 8.0	800 to 1600	1.5 to 3.0
Injection—			
Inj. Fe B.P. ^{6 20} ..	5.0 to 10.0	16 to 32	100

Organic.—As already indicated, only the non-hæmoglobin-like part of the iron of the food is available, and hæmoglobin and similar compounds do not exert the therapeutic action of iron.

It is obvious that iron is most active when given by injection, but in practice parenteral administration is contra-indicated by its dangers. The therapeutic dose of iron by injection (iron and ammonium citrate equivalent to 32 mg. iron) is so close to the toxic dose (48–80 mg. iron) that effective treatment can hardly be given by this route.^{6 20} I have seen toxic symptoms from the injection of 14 mg. of iron a day in the form of iron and ammonium citrate, which is far less than the effective dose. When iron is given by mouth symptoms of general intoxication, as distinct from intestinal irritation, are most unusual, and in spite of the frequent prescription of enormous doses, only one example of severe intoxication from ingested iron is on record.²¹ The amounts of iron which patients have taken with impunity are very large—150 grains a day of reduced iron ³⁹; 150 grains of Bland's pill a day for two or three months ³⁸; 300 grains of iron and ammonium citrate daily ⁴⁷; and while higher dosage than necessary is unwise

there is no excuse for giving too little. The most important lessons from recent work on iron are the futility of injecting iron and the safety of large doses by mouth.

The therapeutic activity of preparations of iron by mouth is directly proportional to their solubility and to the ease with which they yield free ions of ferrous iron. Metallic iron, colloidal ferric preparations, and the scale preparations, in which the iron is in a complex form and not readily ionised, all require to be given in large doses to produce effects. The soluble ferrous salts are the most active. The average effective dose of ferric chloride has not yet been worked out with any degree of accuracy, but from some uncompleted experiments by N. S. Plummer and myself it must be higher than 400 mg. of iron a day, equivalent to liq. ferri perchlor. minims 40 t.d.s. We have obtained incontrovertible evidence that ferric chloride is less potent than ferrous chloride or ferrous sulphate by the method of the double reticulocyte crisis. In these experiments, after a control period, we have treated the patient for a short time with the equivalent of 200 mg. of iron a day as ferric chloride, and have afterwards given the same amount of iron as ferrous chloride or ferrous sulphate. The higher potency of the ferrous salts is revealed by the occurrence of a second reticulocyte crisis and by an acceleration in the rate of hæmoglobin formation. Similar results have been reported by Reimann and Fritsch. On the other hand it is clear that ferric salts are effective if given in sufficient amounts. Their relative inferiority cannot be explained by precipitation on contact with food residues, as colloidal ferric preparations are less effective than the astringent preparations. It is possible that iron is not absorbed in the ferric valency, and that ferric salts are reduced to the ferrous state in the alimentary tract before absorption; on this account they are less potent than the preformed ferrous preparations (Fig. 2).

The most active preparation of iron is not necessarily the most suitable for prescription, and the choice of a preparation for medicinal use is governed by a number of additional factors such as price, palatability, tolerability, durability, and ease of prescription. The soluble simple salts of iron are all irritating to the stomach. The ferrous salts tend to oxidise in solution, though this may be inhibited by avoiding over-dilution and making up the mixture with glucose and/or acid; if they are given in solid form they may cause vomiting, whilst tablets become

hard and insoluble unless carefully and freshly prepared. The solution of ferric chloride is intensely irritating, and I found it quite impossible to use it in effective doses till I learnt the device of adding it to milk immediately before taking.¹⁴ The massive amounts of iron which must be ingested when reduced iron, colloidal ferric iron, or the scale preparations are used, may cause indigestion, diarrhoea, cramps, and constipation,¹⁹ and even intestinal obstruction.⁴³ There is also evidence that large amounts of unabsorbed iron in the intestine may interfere with the absorption of other minerals^{5 46} and vitamins.⁴ The ideal preparation of iron still awaits discovery, but the following are some useful and cheap prescriptions:—

Ferrous chloride (Howard)	3 grs.
Syrup	15 minims
Chloroform water	to 1 drachm
e lacte, t.d.s., p.c.			
Pil. ferri. carb.	15 grs.
t.d.s., p.c. To be crushed before taking.			
Iron and ammon. citrate	30 grs.
Glycerin	15 minims
Chloroform water	to 1 oz.
t.d.s., p.c.			

Among proprietary preparations, which are sometimes more highly esteemed by patients on account of their elegance and costliness, one may mention Ferronyl (ferrous chloride), Oppenheimer's Bipalatinoids (ferrous carbonate), and Idozan (ferric hydroxide).

In the Table I have estimated the percentage of the dose of iron administered which is utilised in the manufacture of hæmoglobin when there is an increase of 1 per cent. a day, using the following calculation¹⁵:

Blood iron corresponding to 100 per cent. hæmoglobin = 50 mg. per 100 c.cm.
 Blood volume = 5 litres.
 Thus a rise of 1 per cent. hæmoglobin is equivalent to a gain of 50/100 x 50 = 25 mg. of iron as hæmoglobin.

The utilisation of an average effective dose of ferrous iron is approximately 20 per cent., and if minimum effective doses of ferrous iron are prescribed, between 50 and 100 per cent. of the dose ingested may be utilised for hæmoglobin formation. Reticulocyte crises and repair of anæmia may be observed with a daily dosage as low as 22 mg. of ferrous iron by mouth. The massive dosage of some preparations of iron has led to a good deal of misunderstanding of the mode of action of the metal, but there now seems no doubt that the effective dosage of preparations of iron is

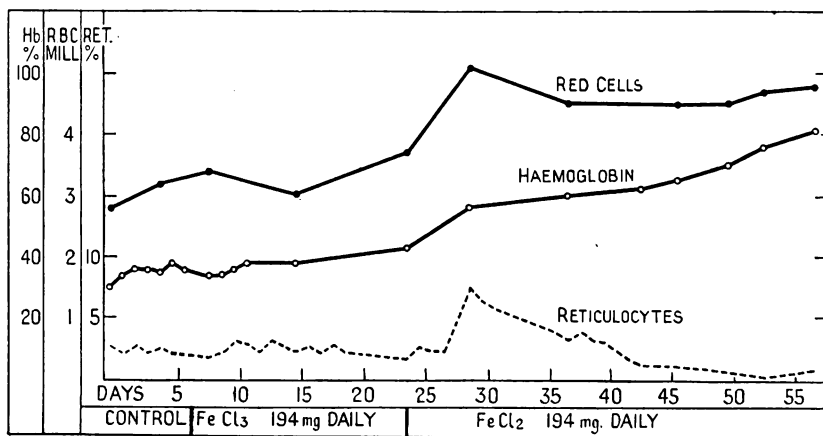

FIG. 2.—Superiority of bivalent ferrous over trivalent ferric chloride when given in doses containing equal amounts of the metal.

directly proportional to the ease with which they yield free ferrous ions. The effective dose of soluble ferrous salts is small and of the same order as the iron contained in the food. The action of iron on the blood-forming organs can be simply explained as the provision of a raw material for the manufacture of hæmoglobin. The administration of iron also relieves the soreness of the tongue and the fissuring at the corners of the mouth, the dystrophy of the nails, the atrophy of the skin, and the bruising and menorrhagia, which often accompany hypochromic anæmia and are probably due to lack of iron in the

tissues. Excess of iron has no influence on hæmopoiesis in health, nor does iron provoke blood formation in the same way as oxygen-want, arsenic, or X rays, so that we are probably correct in assuming that iron is a nutrient and not a stimulant for the blood-forming organs.

To a large extent iron is used to repair deficiencies which would not have occurred had the diet been satisfactory, and as the hygiene and nutrition of the world improve, we may expect conditions such as the "physiological" anæmia of pregnancy, the nutritional anæmia of infancy, and the anæmia of hookworm infestation to follow chlorosis into the limbo of vanished diseases. But the value of diet in anæmia is essentially prophylactic, and when the iron supplies of the organism are exhausted it is hard to replenish them in a reasonable time from the food. We can foretell no decrease in those forms of anæmia which cannot be prevented by diet alone, such as idiopathic hypochromic anæmia and pernicious anæmia, in which the absorption of iron is impaired, and splenic anæmia and chronic hæmorrhagic anæmia, in which excessive amounts of iron are lost. The metal iron is sacred to the god of war, but even in that distant day when swords are beaten into ploughshares, and the peoples of the world are fed not with bread alone, but with diets adequate in biological proteins, vitamins, and minerals, the physician must preserve his skill in the therapeutic use of iron.

Summary

(1) The factors which affect the requirement, the absorption, and the utilisation of iron are discussed.

(2) The absorption of the iron contained in food or drugs is proportional to the ease with which ferrous ions are liberated.

(3) Iron acts as a nutrient and not as a stimulant for the blood-forming organs.

GASTRIC ACIDITY AND ITS SIGNIFICANCE

A CLINICAL AND EXPERIMENTAL STUDY

By FRANK L. APPERLY, M.D. Oxon., D.Sc. Melb.

PROFESSOR OF PATHOLOGY IN THE MEDICAL COLLEGE OF VIRGINIA, RICHMOND, VA., U.S.A.

THE literature relating to variations in gastric acidity, and their significance, is vast and conflicting. Standards of normal acidity for healthy people, and for different sexes and ages, have been set up, although every degree of acidity and even achlorhydria are found in perfectly healthy individuals. In this paper an attempt is made to bring together various experimental and clinical facts into a correlated whole, so that we may better understand not only how gastric acid is regulated and variations are produced, but the significance of these changes, and their bearing on general bodily conditions.

The concentration of hydrochloric acid in pure gastric juice has been given different values by many observers. The recent and most careful work of Hollander and Cowgill¹ however shows that the pure parietal juice has an acid concentration of 0.170 N (pH 0.91), a figure which is independent of rate of secretion or type of stimulus. Variations in acidity are brought about by admixture with mucus and solutions of sodium chloride and bicarbonate, secreted by the gastric mucosa and in some cases regurgitated from the duodenum.

We are, however, more concerned here with variations in acidity at various times after a standard meal irrespective of the mechanism by which these changes are brought about.

THE RELATION OF ACIDITY TO BLOOD CO₂

In 1931 Apperly and Crabtree² showed that variations in the CO₂-content of the fasting blood plasma not only governed the acidity of the gastric contents after a test-meal in any one individual, but were also responsible for the differences in gastric acidity between different individuals (Fig. 1). In 1932 Browne and Vineberg³ confirmed these results in

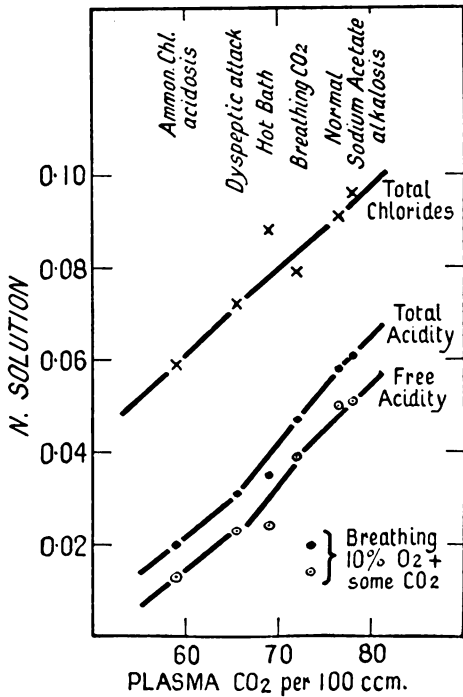

FIG. 1.—Relationship of (a) total chloride, total acidity, and free HCl of gastric contents one hour after the commencement of a test-meal, to (b) the CO₂ capacity of the fasting blood-plasma in one individual under various conditions of acidosis, alkalosis, &c. (from Jour. of Physiol.³).

dogs and further showed that the total amount of acid secreted could be increased or diminished by artificially raising or lowering plasma CO₂.

But what are the factors responsible for variations in plasma CO₂? Does clinical experience show that such variations result in similar variations in gastric acidity? Obviously, of course, the respiratory centre is the immediate regulatory mechanism. But other causes underlie this. Let us therefore correlate what is known about gastric acidity with the conditions in which plasma CO₂ is known to be increased or diminished, and thus possibly obtain some idea as to the significance of these gastric variations. These conditions can be classified thus:—

- (a) Primary CO₂ deficit, commonly associated with some rise of blood pH.
- (b) CO₂ deficit, secondary to loss of blood alkali, associated with fall of pH.
- (c) Primary CO₂ excess, associated with fall of pH.
- (d) CO₂ excess, secondary to rise of blood alkali, associated with rise of pH.

(a) Primary CO₂ deficit is brought about by pulmonary hyperventilation from any cause (except that following respiration of a high CO₂ atmosphere), as for instance by heat, fevers, the earlier stages of oxygen shortage, altitudes, encephalitis, and certain cardiac diseases. The fall of plasma CO₂ following hyperventilation has been shown by Haggard and Henderson;⁴ Collip and Backus,⁵ and Grant and Goldman⁶; that following confinement in a hot room by Cajori⁷; in a hot bath by Bazett,⁸ Kochler,⁹ and Landis¹⁰; and in the tropics by Sundstroem,¹¹ Radsma et al.,¹² and others. The lowering of gastric acidity under each of these conditions has been demonstrated respectively by Delhougne¹³ and Browne and Vineberg³; by Talbert and Rosenberg¹⁴; by Apperly and Semmens¹⁵; and by Nye and Sippe.¹⁶

Apperly¹⁷ was the first to apply the above facts as a possible explanation of the diminished incidence of peptic ulcer in warmer climates when compared with the incidence in people of similar habits in cooler climates. In a survey of the Australian States he showed that peptic ulcer was commonest in Tasmania (latitude 43° O' S) with an incidence of 135 per 1000 hospital beds per year, and that the figures for the various States gradually diminished, as the Equator was approached, to a minimum of about 28 in tropical North Queensland (latitude 21° 10' S). Later Nye and Sippe¹⁶ showed an increased incidence of achlorhydria and hypochlorhydria in Queensland as compared with the cooler southern States, and in summer as compared with winter. This survey is interesting because in Australia we have, spread over a huge area extending from the tropics to mild and even cold zones, an almost pure Anglo-Saxon race with almost exactly similar dietetic and other habits. When we compare different races with different diets of course this relationship to heat and cold no longer holds—e.g., among the cayenne pepper-eating Abyssinians, and the people of Southern India with their highly spiced foods, it is not surprising to find that the incidence of gastric ulcer is unusually high (Bergsma,¹⁸ Bradfield¹⁹).

A further interesting fact is the hypochlorhydria and achlorhydria of fevers whether of natural origin (Glaessner²⁰) or experimentally produced by vaccines (Vanzant²¹), but it is probable that toxic and other factors than the fall of plasma CO₂, consequent on the hyperventilation of pyrexia (Koehler,⁹ Hachen and Isaacs²²) are operating in these cases.

While the effects of X radiation are still open to some doubt, there is considerable evidence that such treatment results in a fall of plasma CO₂ and a rise in pH (Hussey,²³ Kast et al.,²⁴ Myers and Booher²⁵), i.e., changes similar to those following hyperpnœa; but we have no direct evidence of the effects of the above on gastric acidity and motility. It is, however, of interest to note that X radiation reduces hyper-

FIG. 2.—Relationship of gastric acidity after a 5 per cent. alcohol "meal" in dogs to red cell content of blood.

acidity, and increases intestinal motility even to diarrhoea (Pohle³⁶).

(b) *Fall of plasma CO₂ secondary to a primary alkali deficit* usually follows loss or neutralisation of plasma alkali by exogenous or endogenous acids.

The simplest case is that in which the ingestion of sufficient ammonium chloride lowers both plasma CO₂ (Haldane,²⁷ Gamble et al.,²⁸ Apperly and Semmens¹⁵) and gastric acidity, with a prolongation of gastric emptying-time (Apperly and Crabtree²). Clinically, the same phenomena are exhibited in the diminished gastric acidity in the later stages of pregnancy (Nakai,²⁹ Davies and Shelly³⁰) in which there is a fall of plasma CO₂ due to alkali deficit (Bock,³¹ MacNider,³² Rowe et al.,³³ and others); by the fall of gastric acidity after severe exercise (Hellebrandt and Miles³⁴) in which lactic acid causes a fall in blood CO₂ (Bock and Dill,³⁵ Boje,³⁶ and others); by the generally lowered acidity in those of poor physical fitness (Bloomfield and Keefer³⁷) in whom there is also usually a lowered plasma CO₂ (Osman and Close³⁸); and by the hypochlorhydria and anacidity of chronic nephritis (Jones,³⁹ Friedenwald and Morrison⁴⁰) in which plasma bicarbonate is so commonly diminished (Henderson, Bock et al.,⁴¹ and many others).

As regards the effects of diabetic acidosis, several text-books state that achlorhydria and hypochlorhydria are commonly found, but I am unable to find any statistics corrected for age and sex to compare with the figures for normal people. It is interesting, however, that insulin increases the secretion of gastric acid (Roholm,⁴² Collazo and Dobreff⁴³), the acidity after a test-meal (de Ancaies⁴⁴), and gastric motility (Dickson and Wilson⁴⁵).

Of the effects on gastric acidity of starvation and the diarrhoeal disease, in both of which plasma bicarbonate is diminished,^{79 80} there appears to be no definite evidence; immediately after starvation there appears to be some diminution of total acid

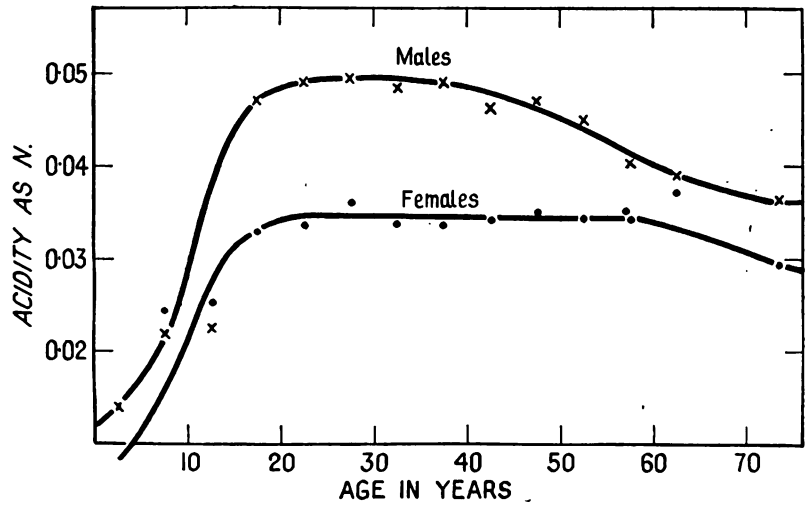

FIG. 3.—Variations of average normal gastric acidity with age and sex (after Alvarez, Vanzant et al.⁵⁴).

secretion in dogs (Kunde⁴⁶) but in man Carlson⁴⁷ could find no such changes.

It is somewhat difficult to place the various anoxæmias in the classification here used. In all cases hyperventilation leads to diminished plasma CO₂, as in hæmorrhage (Bennett,⁴⁸ Buell⁴⁹), at altitudes (Barcroft,⁵⁰ Wittkower,⁵¹ Fitzgerald⁵²), and after breathing a low-oxygen atmosphere (Koehler,⁵³ Haggard and Henderson⁴). Whereas, however, in the early stages the loss of CO₂ directly follows hyperventilation with rise of blood pH—which would tempt us to classify this group under Class (a)—in the later stages lactic acid formation neutralises part of the plasma alkali, with a fall of pH. Most of the cases here discussed fall into the latter group which is therefore classed under (b). In each of the cases mentioned above a lowered gastric acidity has been demonstrated—e.g., at altitudes by Delrue in the case of dogs⁷¹—and by Apperly, Crabtree, and Norris for man (unpublished); after breathing an oxygen-poor atmosphere (Crisler, Van Liere, and Wiles,⁵⁴ Apperly and Crabtree, unpublished); and in some of our own observations following hæmorrhage in both dogs and man. In most of the above instances the stomach emptying-time was retarded.

Fig. 2 shows the results in one of our series of experiments on dogs, in which anæmia and polycythæmia were artificially produced by bleeding and transfusion.⁹¹ It will be seen that gastric acidity rose with red cell content up to a maximum at or slightly above the normal content. (Beyond this, with increasing polycythæmia, acidity fell again. The reasons for this will be dealt with elsewhere.) Similar figures were found in normal and anæmic patients. Not only do we have acidity changes with the grosser forms of anoxæmia, but also corresponding to those variations of hæmoglobin which are within normal limits.

Without going into our

FIG. 4.—Variations of average normal hæmoglobin or oxygen capacity with age and sex (modified from Peters and Van Slyke⁵⁵).

experimental work here, we will merely mention the most interesting and striking similarity between the graph representing the average gastric acidities for different age- and sex-groups (as determined by Vanzant, Alvarez et al. from 3746 cases,⁵⁵ Fig. 3) and the graph showing the average hæmoglobin content of the blood for similar age- and sex-groups (from Peters and Van Slyke,⁵⁶ Fig. 4). Further, when the figures in these two graphs are plotted against each other, a straight line relationship is revealed (Fig. 5). We have of course found a considerable individual scattering about these average curves. These charts suggest two things: (1) that variations in average gastric acidity for different age- and sex-groups are at least

FIG. 5.—Relationship of average gastric acidity of different age and sex groups (taken from Fig. 3) to average hæmoglobin for the same groups (taken from Fig. 4).

partly dependent on hæmoglobin differences, or whatever causes the latter; and (2) that, assuming the straight line in Fig. 5 continues as such to the base-line, gastric acidity disappears when the hæmoglobin content of the blood falls to about two-thirds its normal value—i.e., that anæmia can bring about achlorhydria. We have indeed found this in patients with post-hæmorrhagic anæmia. This observation is of great interest in view of the well-known work of Witts and others on the reverse relationship—i.e., that certain anæmias are preceded and caused by achlorhydria. It would appear that we will have to distinguish between Witts's achlorhydric anæmia and our anæmic achlorhydria. We hope to publish these and other observations in the near future.

Dr. Alvarez has suggested to me that the changes in acidity and motility may explain the fact that the symptoms of peptic ulcer often improve after a severe hæmorrhage.

(c) *Primary CO₂ excess* in the plasma is brought about either by breathing an atmosphere containing an excess of CO₂ gas (Davies et al.⁵⁷), or by any process that interferes with the elimination of CO₂ from the blood—e.g., in emphysema (Scott,⁵⁸ Dautrebande,⁵⁹ Peters et al.⁶⁰), or during an asthmatic attack (Osman and Close,³⁸ Apperly and Norris (unpublished)).

Bakaltschuk⁶¹ and Apperly and Crabtree² showed the rise in acidity brought about by breathing an atmosphere containing 3–5 per cent. CO₂ or by rebreathing one's own CO₂. Johnston and Washeim⁶² showed the same result during sleep, when plasma CO₂ rises, possibly on account of a diminished sensitiveness of the respiratory centre, resulting in CO₂ retention (Endres⁶³).

R. J. Main, in this laboratory, has shown a close linear relationship between alveolar CO₂ per cent. and the ratio of pulmonary vital capacity to body surface (unpublished)—i.e., that healthy large-lunged individuals have a higher alveolar CO₂. Full and Herxheimer⁶⁴ have also found a decidedly higher average alkali reserve in athletes than in untrained men. This high blood alkali or CO₂ in normal people indicates an optimum oxygenation (Gesell⁶⁵). It is therefore not surprising that the big-chested, athletic type of man has, on the whole, a higher gastric acidity than the opposite physical type (Campbell and Conybeare,⁶⁶ Vogeler⁶⁷). Apperly and Semmens¹⁵ demonstrated a rough correlation between gastric acidity and the ratio of pulmonary vital capacity to body-weight.

Another cause of increased plasma CO₂ is constriction of the bronchioles. We have found this in a number of asthmatics during an attack, but of the effect on gastric acidity of bronchiolar constriction brought about, for example, by asthma, noxious gases, and possibly by smoking with inhalation, we know nothing. The hyperchlorhydria of many smokers is generally attributed to the direct effect of swallowed irritants on the gastric mucosa. Possibly an increased bronchiolar constriction, reflex or direct irritation, might be a factor.

(d) *Increased plasma CO₂ secondary to primary alkali excess* has been demonstrated experimentally after the ingestion of large doses of sodium acetate and other alkaline salts by Davies and Haldane,⁵⁷ Palmer et al.,⁶⁸ Gesell and Hertzman,⁶⁹ and others, and clinically during a course of Sippy's diet (Kast,²⁴ Myers and Booher²⁵). That gastric acidity is raised under the same conditions has also been shown by Apperly and Crabtree² and by Hardt and Rivers⁷⁰ respectively. The former also observed an increased gastric motility.

The accompanying Table is a summary of the above observations.

RELATION OF GASTRIC ACIDITY TO BLOOD pH

In the Table Groups (a) and (b) are associated with diminished plasma CO₂ and (c) and (d) with increased plasma CO₂. On the other hand, those conditions in which pH is increased are found in Groups (a) and (d), while (b) and (c) contain those associated with a fall of pH. It will be seen that gastric acidity follows variations in CO₂, but has no relationship to blood pH.

RELATION OF GASTRIC MOTILITY TO BLOOD pH

Although few observations have been made on the relation of gastric motility to blood chemistry, the evidence presented above and summarised in the Table shows that experimental and clinical variations of the plasma CO₂ associated with increased gastric motility fall in Groups (a) and (d), while those associated with a retarded emptying rate fall in Groups (b) and (c). This seems to indicate that blood pH is a factor in determining gastric motility, these two varying in the same direction.

PRACTICAL CONSIDERATIONS

The preceding suggest some possible practical applications:—

1. Hyperchlorhydria and the symptoms associated with it might be diminished by, among other things, (i) removal to a warm climate, (ii) artificial fever, (iii) heat treatment, (iv) bleeding, and (v) the substitution of oxides and non-absorbable bicarbonates for the usual sodium bicarbonate treatment, since the latter salt in large amount, by increasing plasma CO₂, may actually raise gastric acidity.

2. Certain of the hypo-acid dyspepsias are more likely to be influenced by attention to the underlying anoxæmia or acidosis than by direct local treatment. A search for the causes of a low plasma CO₂ may be fruitful, since it may give a clue to the underlying pathological conditions.

3. In dealing with cases in which achlorhydria or hypochlorhydria is associated with anæmia, it might be well to investigate which of these conditions is primary—i.e., whether we are dealing with an anæmic achlorhydria or an achlorhydric anæmia (Witts).

SUMMARY

Gastric acidity after a meal is chiefly a function of the blood CO₂. In normal people this is regulated by the hæmoglobin content of the blood, by the ratio of the pulmonary vital capacity to body-weight (or surface), and by temperature. Under abnormal conditions anoxæmia, anæmia, altitudes, pregnancy, nephritis, fevers, diabetes, severe exercise, and lowered physical fitness may diminish plasma CO₂ and therefore gastric acidity. Asthma, emphysema, &c., which raise plasma CO₂, would be expected to raise gastric acidity, while encephalitis, X radiation, and certain cardiac conditions, which lower plasma CO₂, would be expected to lower gastric acidity; but these effects have not been investigated. The acidity of the gastric juice is a rough measure of the alkali reserve of the blood (except in marked anæmia), while the rate of gastric evacuation would seem to be influenced partly, at least, by blood pH. A consideration of the possible causes of such variations of plasma CO₂ and pH may give valuable hints as to the pathological conditions underlying certain dyspepsias.

There is also a direct relationship between the red cell content of the blood and gastric acidity. When the former falls to about half or two-thirds normal (on the average) free acid disappears from the stomach. A distinction is therefore made between the achlorhydric anæmia of Witts and anæmic achlorhydria.

Part of the expenses connected with this work was generously borne by Parke, Davis and Co.

THE INHIBITORY EFFECT OF FOLLICULAR HORMONE ON THE ANTERIOR LOBE OF THE PITUITARY GLAND

BY BERNHARD ZONDEK, M.D.

PROFESSOR IN THE HEBREW UNIVERSITY OF JERUSALEM

(From the Gynecological and Obstetrical Department of the Hadassah-Rothschild Hospital, Jerusalem)

In previous papers I have been able to determine the following facts. The anterior pituitary is the motor of sexual function. The gonadotropic hormones of the anterior pituitary represent the superior sexual hormones. The anterior lobe stimulates the secretion of (a) folliculin (œstrin) in the theca cells by means of prolán A (follicle-stimulating hormone), and (b) progéstin, in the granulosa cells by means of prolán B (luteinising hormone). Without the anterior lobe there is no folliculin. The follicular hormone, produced in the ovary through the action of the follicle-stimulating hormone (prolán A), reacts in its turn upon the anterior lobe.

The present paper is a preliminary report of experiments in which I have studied the inhibitory effect of the follicular hormone given over long periods in amounts much larger than those ordinarily produced in the body—given, that is to say, as a drug. Elsewhere I shall report the effect of these large doses of follicular hormone on its effector organ, the uterus, and I now propose to describe their effect on the controlling gland, the anterior pituitary.

My first finding is that the harmonic function of the anterior pituitary can be inhibited.

INHIBITION OF THE GROWTH HORMONE

The experiments were performed on rats. Infantile rats, 3-4 weeks old, weighing 25 g., received subcutaneous injections of follicular hormone twice a week. These injections consisted of either α -hormone in aqueous or oily solution, or the benzoic ester of the dihydrofollicular hormone (Dimenformon).* The control animals received injections of normal saline or olive oil. In doses of 100 M.U. (mouse units) twice a week folliculin had no effect on body growth. After four months' treatment, with a total amount of 2900 M.U., the treated animals were of the same size and weight as the controls. On the other hand, when 1000 M.U. was applied twice a week, definite inhibition of growth was seen in 4½ weeks (after a total of 9000 M.U.). The larger the amount of hormone, the greater the inhibition of growth. The effect is very obvious if 5000 or 10,000 M.U. dimenformon is applied twice a week. A slackening of growth is apparent within a short time, though it only becomes really definite when the animals have reached the juvenile stage and weigh 70 g. While the weight curve steadily rises in the control animals, the curve of those which have been treated remains constant or rises very little. After 3-4 months' treatment—e.g., after the application of 100,000-200,000 M.U.—a difference in weight amounting to as much as 43 per cent. may be shown. For instance, the control animals weigh 164 g., and the treated animals 96.5 g.

If the experiments are performed on juvenile animals with a weight of 70 g., their growth may

* I am indebted to the Organon (Oss) for kindly supplying large amounts of Folliculin Menformon and Dimenformon.

similarly be inhibited. The application of 5000 M.U. folliculin twice a week produces inhibition after three weeks (total 30,000 M.U.), and if continued for 3-4 months (120,000-160,000 M.U.) leads to a difference in weight amounting to 20 per cent. The earlier the experiments are begun—i.e., the younger the animals—the more striking is the inhibition of growth. It is seen equally in male and female animals.

The relation between growth inhibition and the dose of hormone is shown in the accompanying Table. The inhibition affects the skeleton as well as the organs. The treated animals are shorter, and

Table showing Growth Inhibition resulting from Follicular Hormone

(A) INFANTILE ANIMALS

Sex.	Preparation.	Dose.	Duration of treatment in weeks.	Total amount Foll.-Menf. in m.u.	Growth inhibition shown by reduction of weight, per cent.

(B) JUVENILE ANIMALS					
F.	Foll.-Menf. oily sol.	5000 m.u. twice a week.	15½	155,000	26.3
F.	Foll.-Menf. aqu. sol.	"	17½	190,000	23.5

* No treatment from 8/8 to 21/8. Foll.-Menf. = Folliculin-Menformon. aqu. sol. = aqueous solution. oily sol. = oily solution.

amounts of follicular hormone. The younger the animal, the more intense the inhibition. The retardation is particularly conspicuous during the puberty of the rats—i.e., at a weight of about 70 g. H. M. Evans and Long were able to demonstrate that the growth of rats can be increased by injection of anterior pituitary extracts. My experiments show, conversely, that large doses of follicular hormone may destroy the effect of the growth hormone of the anterior pituitary. Evans and Long produced giant animals by means of growth hormone, while I produce dwarf animals by means of follicular hormone. The fact that the inhibition of growth results from the paralysis of the growth hormone caused by the follicular hormone becomes evident when we find that the gonadotropic hormones which are produced in the anterior lobe may equally be inhibited.

INHIBITION OF THE GONADOTROPIC HORMONES

The sexual organs of the animals whose growth has been inhibited by follicular hormone show definite changes. Prolonged application of the hormone induces a continuous oestrus, with the result that vaginal smears regularly show cornified cells. The vagina is thickened and hyperplastic, and the mucous membrane proliferates. The uterus also shows much enlargement, and the myometrium is in the stage of pronounced proliferation. These enlarged genital organs contrast remarkably with pale and small ovaries, which may undergo so great an involution that they are no longer recognisable as such. While abundant corpora lutea are to be found in the control animals, they are absent in the ovaries of the treated animals. In serial sections small follicles are usually to be found, also some follicles of average size, but rarely large follicles, and never corpora lutea. This difference clearly manifests itself in reduction in the weight of the ovaries. When the application of follicular hormone was started in the juvenile stage (the animals weighing 70 g.), administration of 165,000 M.U. during 16 weeks caused a reduction of, e.g., 20 per cent. in body-weight and 58 per cent. in the weight of the ovaries. The ovaries of the control animals weighed 37 mg., those of the treated animals 15 mg.

The development of the ovaries is retarded by the prolonged application of follicular hormone; the follicles do not rupture, and corpora lutea are not formed. This effect undoubtedly originates in the following fashion: follicular hormone paralyses the gonadotropic hormones of the anterior pituitary—and, as it appears, the luteinising hormone, prolactin B, in particular—thus hindering them from exerting their normal influence on the ovaries.

The same reaction is to be observed in the male. It has long been known that folliculin has an anti-masculine effect, and that the testes diminish in size when it is administered. The way in which this happens has not hitherto been explained, but my experiments demonstrate that it is due to inhibition of those hormones of the anterior pituitary which stimulate testicular development. In the experiments previously described by other workers and by myself, relatively small doses of folliculin were used; but I am now able to show that if male rats are given doses sufficient to arrest their body growth tremendous changes in the testes are produced. This may be illustrated by the following example.

Male rat, 4 weeks old, and weighing 30 g., received one injection of 15,000 M.U. dimenformon, followed by regular application of 5000 M.U. twice a week. After three months' treatment, with the total dose of 155,000 M.U., the animal

the bones are more delicate. As an example I report the differences in weight of one of the experiments.

Control animal.—The femur weighs 0.35 g., tibia and fibula 0.31 g.

Folliculin animal (R 117) (five months' treatment with a total of 205,000 M.U.)—The femur weighs 0.29 g., tibia and fibula 0.24 g.—i.e., a difference in weight of 17 and 22 per cent. respectively.

The anatomical changes in the epiphyseal lines will be reported in a separate communication.

Mention may further be made of changes in the fur of animals under treatment. The hair is rough and shaggy, and shows a tendency to fall out, particularly in the gluteal region.

The experiments demonstrate the possibility of inhibiting growth by prolonged application of large

weighs 94 g., while the control animal weighs 160 g.† —a difference of 41 per cent. In the control animal the weight of the mature testis was 1000 mg., but in the treated animal only 50 mg.—a difference of 95 per cent. The testes of the treated animal remained at the infantile stage seen in animals two weeks old.

The development of the genital apparatus (testis, spermatogenesis, prostate, and seminal vesicles) is completely arrested by prolonged application of folliculin.

In a further report I hope to describe the effects of large doses of folliculin on the thyrotropic hormone and other hormonotropic active principles, as well as the changes in the anterior lobe of the hypophysis of the treated animals. The importance of these results in clinical work will be discussed later.

INTRAVENOUS CURARINE IN THE TREATMENT OF TETANUS

BY RANYARD WEST, M.D., M.R.C.P. Lond.

BEIT MEMORIAL RESEARCH FELLOW; DEMONSTRATOR OF PHARMACOLOGY IN THE UNIVERSITY OF OXFORD; ASSISTANT PHYSICIAN TO THE SEAMEN'S HOSPITAL, GREENWICH

CURARINE is the commonest active principle of curare. It is responsible for the characteristic action of the curares of British Guiana and its presence in these is constantly due to the bark of a ligneous vine, *Strychnos toxifera*, which is a chief ingredient of the native mixture.

Curarine is a quaternary alkaloid which can be prepared in crystalline form either from suitable curare or direct from *S. toxifera*. It is the latter source which has enabled the alkaloid to be prepared in quantity recently (King, 1935).

The action of curarine is the classical one of curare—a paralysis of muscle from a failure of the effective transmission of the impulses travelling to it along the motor nerve. Death from curarine is due to asphyxia following failure of the respiratory muscles. But the paralyzing action of curarine is not necessarily sudden, complete, and universal; it is graded quantitatively and has a selective anatomical distribution. Experimentally, in animals, small doses cause a failure of *maintenance* of contraction (response to electrical tetanus) while the response to single stimuli remains good. Recently curarine has been found to act selectively on certain rates and strengths of electrical stimuli (Briscoe, 1935). Further, the pathological conditions of decerebrate rigidity in the cat and of experimental local tetanus have been found by Bremer (1927) to respond selectively to curare, and, in the case of decerebrate rigidity, to curarine (1935). Anatomically, the order of sensitivity of muscles is strikingly constant, viz.: (1) muscles receiving a cranial nerve-supply; (2) the skeletal muscles generally, including the intercostal muscles; and (3) the diaphragm.

Curare has been introduced into therapeutics and abandoned on many occasions since the middle of last century. The irregular strengths and compositions of curares would make their standardisation very difficult. Curarine was isolated from curare by Preyer (1864) and tried therapeutically by Hoffmann (1879). It was prepared from *S. toxifera* by Boehm and given to a case of tetanus by Hoche (1894), (Hale-White, 1901). Recent partial successes

† The control animals received olive oil subcutaneously twice a week in the same amounts as were used for the oily solution of dimenformin in the treated animals.

in treating chronic pathological rigidities with some crude curares (Hartridge and West, 1931; West, 1932) has led to a collection of plant material and a resurvey of the pharmacology of curarine (West, 1935). Meanwhile Cole (1934) and Mitchell (1935) have reported cases of acute tetanus treated with curare and with curarine respectively. Florey, Harding, and Fildes (1934) gave curarine to animals in experimental tetanus.

In our animal experimentation it was noticed that, in the cat, a clear removal of decerebrate rigidity without failure of respiration could be maintained only by giving the drug very slowly. The intravenous route was found much safer than the subcutaneous in that by its partial recovery will occur within a few minutes of stopping the inflow of the drug. A tendency to bronchial spasm and hypersecretion was met by atropine or adrenaline, for rapid action the latter being preferable. This intravenous technique was transferred to man and tried in a volunteer suffering from advanced parkinsonism. The method finally adopted, and here described, forms a provisional suggestion for the treatment of severe cases of tetanus.

Method of Treatment

The apparatus used is the following:—

1. An intravenous drip outfit, with duplication of reservoir and dripper. The dripper must be calibrated. The Canny-Ryall or Farquharson dripper commonly delivers from 500 to 700 drops per ounce of fluid. The vein may be entered either by needle or cannula.
2. A malleable gutter splint to fix the arm in a comfortable position.
3. Artificial respiration equipment: endotracheal catheter—e.g., St. Bartholomew's type (grey), small, medium, or large. Two oxygen cylinders, with good fine adjustments on the taps; glass junctions for tubing.
4. Direct-vision laryngoscope.
5. Mason's gag, tongue forceps, mounted swabs (as anaesthetist's tray).
6. Adrenaline solution 1:1000.
7. Curarine chloride in solution, 100 mg. of the solid to a pint of saline or glucose saline.

Dose.—The standard rate of curarine inflow may be taken as 0.25 mg. per kg. of body-weight per hour. The rate of drip required to deliver this may be calculated as follows:—

$$\text{Drops per minute} = \frac{0.25 \times \text{wt. of patient (kg.)} \times \text{drops per oz. from dripper} \times 20}{\text{mg. curarine per pint saline} \times 60}$$

If the curarine is made up at a strength of 100 mg. to the pint, the patient's weight is 70 kg., and the dripper is found to deliver 600 mg. per oz., this becomes—

$$\text{Drops per minute} = \frac{0.25 \times 70 \times 600 \times 20}{100 \times 60} = 35$$

A pint of solution lasts about six hours.

Technique.—An initial dose of atropine (gr. 1/50) is given subcutaneously, and ten minutes later an intravenous needle is strapped in position in a suitable vein on an arm which is splinted so as to flex the elbow at some 30°. (The fully extended arm was found a very painful posture.) A can of warmed glucose saline with a visible drip attachment is connected, and curarine added to the solution so as to deliver 0.25 mg. per kg. per hour to the patient. It is convenient if it is arranged so that this is equivalent to about 30 drops per minute in the dripper. A second can of warmed normal glucose saline connected to the intravenous system near the patient's arm is a valuable means of securing fluid and food to the patient and of preventing clotting in the

needle or vein whenever the curarine-saline has to be turned off.

At first the curarine-saline is run in at six times its "maintenance rate"—e.g., 3 drops per second—so that 0.25 mg. per kg. is delivered in about ten minutes. This should be sufficient for curarisation, and during the administration the patient is closely watched, and, if well enough, interrogated about his sensations.

Curarisation.—A muscular weakness in the distribution of the cranial nerves is to be expected as the sign of partial curarisation. The patient may complain that his head is heavy, that his tongue will not move, or of diplopia. Ptosis is usually the first objective sign of curarisation, but weakness of other motor cranial nerves may be noted early. At the first sign of curarisation it is wise to halve the rate of inflow. But, speaking from my present limited experience, I would designate as the best sign of effective curarisation a change in the breathing. A nurse will record the breathing as "shallow." Actually intercostal respiration almost or quite ceases, abdominal (diaphragmatic) respiration continuing steadily and without effort. The change is often sudden and indicates that curarisation has gone as far as it can be taken unless respiratory failure is to be courted deliberately.

On completion of the induction of curarisation, the inflow is stopped for about five minutes and then restarted at the maintenance level of 0.25 mg. per kg. per hour. For the first hour its effects should be watched closely, as the rate may be too high and lead to an actual shallowness or a visible effort in abdominal breathing, or too low, with resultant return of intercostal breathing or an increase of the pathological rigidity.

In a case of tetanus with persistent tonic rigidity of jaw, neck, and abdomen, there should be marked, if not complete, relaxation of these muscles when curarisation has occurred to the level indicated. With an ordinary sized dripper (e.g., the Canny-Ryall) a pint of curarine-saline, dripping at a rate of 30 drops per minute, may be expected to last about six and a half hours. Animal experiments suggest that atropine (gr. 1/100 to 1/50) should be given subcutaneously every four hours, if bronchial spasm and hypersecretion are to be avoided. Should they occur, adrenaline is probably a better immediate remedy.

It is not yet possible to say how long treatment by curarine drip can be maintained in tetanus. In Case 2 (below) it was continued for 20 hours without difficulty, other than from (avoidable) clotting in the needle.

Sleep remains an important desideratum. I think a small nightly dose of morphine may be given safely, and the treatment is not incompatible with *light* Avertin anaesthesia (0.05 c.cm. per kg.). The patient to whom this was given slept well and yet lightly for three hours. Weakness of the muscles of deglutition may cause difficulties and accidents in swallowing, and if these occur a feeding-tube should be passed early and kept in position as long as is necessary.

If dangerous spasms occur they are likely to be respiratory in type, and particularly bronchial. These may be due to the tetanus. But pure curarine is itself capable of causing bronchial and laryngeal spasm in animals, and the history of one patient (Case 13) shows this to be a real danger of curarine in man. So sudden may the onset of the spasm be, that, even when it is watched for and the requisite apparatus is immediately to hand, it may be difficult

to deal with. An intermittent closure of the glottis occurs, and an endotracheal catheter has to be passed during the first possible moment of relaxation if the patient's airway is to be secured. I have used the St. Bartholomew's type (grey) intratracheal catheter in one emergency of this kind, and found it satisfactory. A rapid stream of oxygen should be delivered through the catheter. Consciousness is lost very early; the catheter should be retained until there are signs of its return, and only removed then if spontaneous breathing is active.

In critical cases of tetanus adequate relaxation may be incompatible with the retention of spontaneous respiration. Curarisation may then be deliberately deepened, and a means of artificial respiration provided. The Bragg-Paul Pulsator (Messrs. Siebe Gorman and Co.) can be used. But in view of the risk of bronchial spasm it is essential to be able, in addition, to deliver oxygen directly to the lungs by the endotracheal catheter. For, in animals under severe curarine spasm, it is impossible to perform effective artificial respiration by a compression method.

Ten Cases of Tetanus

The accompanying Table summarises 10 cases of tetanus treated during 1935. They illustrate the observation that when the incubation period is under seven days or the period of development of symptoms to the point of generalised convulsions less than three days, death must be expected whatever the treatment adopted. Cases 1, 2, 3, 4, 8, 9, and 10 fall into this category, and though their treatments were various, all the patients died. Of these 7 cases it will be noted that, in 5, death occurred not later than the day after the onset of general convulsions. The exceptions are Cases 2 and 10. The former was given intravenous curarine, the latter avertin in repeated doses. Case 10 was exceptional in the very long incubation period of 19 days being followed a day later by generalised convulsions. On the twenty-second day of his illness the patient, a man of 63, appeared to be improving. Acute hyperpyrexia occurred, with cardiac failure, on the twenty-third day. The case treated with curarine (No. 2) is described below.

Of the three cases in which the outcome was reasonably in doubt (Nos. 5, 6, 7) two had an incubation period of seven days, and one of these recovered. Cole (1934) recorded the treatment of such a patient with curare and his subsequent recovery. This patient (No. 5) was a boy of 13. He received no curare and no special treatment beyond repeated anti-tetanic serum and a chloral and bromide mixture.

CASES TREATED WITH CURARINE

CASE 2 was extremely severe. The incubation period was five days and the generalised convulsions occurred on the following day. On admission, 60,000 units of antitetanic serum had been given. Paraldehyde grs. 60 and bromide grs. 40 had been given repeatedly. I saw the patient early on the seventh day. There was a high degree of tonic spasm of the jaw, neck, and abdominal muscles.

Treatment.—After atropine gr. 1/50, curarine 12 mg. was given intravenously, taking seven minutes over the injection. Complete ocular ptosis resulted, with partial relaxation of the muscles of the jaw, neck, and abdomen. Curarine is rapidly excreted, and much of the rigidity returned within 30 minutes. When full rigidity had returned, 10 mg. of curarine in 10 c.cm. of solution was injected intravenously during four minutes. Full relaxation of the trismus occurred, the patient supporting his fallen jaw in his hand. Relaxation of the neck and abdominal muscles followed. Fifteen minutes later, and

Table of Cases of Tetanus, 1935

Case and age.	Incubation and development.		Treatment.		Outcome.
	Probable site of infection.	(a) Onset. (b) Convulsions. Day.	Serum and period. Units.	General and special.	
1 (9)	Splinter in foot.	(a) 5th (b) 6th	490,000	Sedatives.	Fatal spasm on 2nd day of symptoms, 7th day.
2 (27)	Nail in foot.	(a) 5th (b) 6th	200,000 3 days.	Curarine intravenously 20 hours. Avertin 0.05 c.cm. per kg. once.	8th day. Resp. spasm and asphyxia.
3 (c. 50)	?	(a) 5th (b) 7th	120,000 2 days.	Avertin 0.05 c.cm. per kg. 2-hourly.	8th day convulsions ceased: hypostatic pneumonia.
4 (9)	Splinter in leg.	(a) (b) 7th	—	—	Death under light chloroform ether anaesthesia, for diagnostic lumbar puncture.
5 (13)	—	(a) 7th (b) 10th	24,000 2 days, 365,000 8 days.	Chloral grs. 10, bromide grs. 15, 4-hourly.	3 convulsions on 10th day. 11th day improving. 34th day recovered.
6 (32)	Nail in foot.	(a) 7th (b) 11th	192,000 2 days.	Curarine intravenously.	12th day. Resp. spasm, cardiac failure.
7 (24)	Cut hand.	(a) 10th (b) 14th	150,000	Curarine subcutaneously.	15th day. Fatal resp. spasm following feeding.
8 (51)	Infected finger.	(a) 11th (b) 12th	200,000 at once.	Avertin 0.1 c.cm. per kg. 6-hourly (reduced).	13th day. Generalised fatal spasm.
9 (38)	Nail in foot.	(a) 13th (b) 15th	120,000 2 days.	Chloral and bromides.	16th day. Fatal spasm (the second).
10 (63)	Compound fracture tibia.	(a) 19th (b) 20th	200,000 3 days.	Avertin 0.05 c.cm. per kg. 4-hourly.	23rd day. Hyperpyrexia and sudden cardiac failure.

during full relaxation, 10 mg. curarine was given subcutaneously. Curarine takes 20–30 minutes to be absorbed from the subcutaneous tissues. Good relaxation was obtained for 2 hours. After 4½ hours full tonic rigidity had returned and small added spasms had commenced at 5-minute intervals. After atropine gr. 1.50, curarine 9 mg. in 9 c.cm. in 4½ minutes was given intravenously. Rigidity was removed but began to return in 35 minutes. Thereupon the curarine intravenous drip was started.

Induction of relaxation was obtained by giving 7.5 mg. in 7 minutes. A lower rate of inflow was then adopted, and 66 mg. was given in each 6-hourly period for 18 hours. During this period the patient remained almost flaccid, slept and was fed. He received two injections of morphine gr. ½, and during the treatment sleep was assisted by one-half dose (0.05 c.cm. per kg.) of avertin rectally. After 18 hours of treatment, difficulty from clotting in the needle caused the return of rigidity, a rapid deterioration in the patient's condition, and the onset of attacks of respiratory spasm. Curarine was restarted as a continuous subcutaneous injection, but it was found impossible to maintain a constant rate of inflow. Further respiratory spasms were difficult to control owing to the difficulty of introducing endotracheal catheters. The patient's own respiration was probably weakened by the curarine, and the strain of right-sided cardiac congestion and anoxæmia caused a comparatively sudden cardiac failure.

The outcome of this case was a disappointment. For it was felt that a patient who had been success-

fully treated for two days after the onset of violent tetanic spasms might have survived if further time could have been given for the progressive removal of his toxæmia.

CASE 6.—The onset of symptoms was on the seventh day, and although generalised spasms did not occur until the eleventh, the case then became critical. A generalised convulsion had occurred during the early morning. During the day the patient was free of spasms, but in the evening they returned and by midnight they were prolonged and severe. The technique described was followed and an intravenous drip established at a rate of 0.27 mg. per kg. per hour. Considerable relaxation was obtained and the patient continued to breathe spontaneously without difficulty. After 3 hours of curarisation spasms involving the bronchial muscles occurred. Four such spasms occurred within an hour and necessitated the passage of the endotracheal catheter. The patient was considerably cyanosed before the catheter could be introduced, and his general condition had deteriorated. After the institution of endotracheal oxygenation there was no further cyanosis, but larger concentrations of curarine (0.4 mg. per kg. per hour) had to be given to maintain flaccidity. Six hours after the commencement of curarisation, and 2 hours after the passage of the catheter, the pulse-rate had risen and there were already signs of pulmonary congestion. The jaw remained relaxed, the neck muscles largely relaxed, the abdominal muscles partly so. The limbs were flaccid, the patellar reflexes which are abolished only in deep curarisation were generally but not always obtainable. It was decided not to stop the curarine inflow, in view of the inevitable return of muscular spasm. But from the time of the last respiratory spasm the patient's condition became worse until death from cardiac failure 2½ hours later.

CASE 7.—In this case the incubation period was ten days, and a further four days elapsed before the onset of generalised spasm. The patient was first seen after these had become very severe. Rapid respiration, tachycardia, and high fever were present. Each spasm arrested respiration for about a minute, and each was expected to end fatally. Curarine 2.5 mg. was given subcutaneously when the case was seen. An hour later the patient was fed through a tube and immediately suffered a long respiratory spasm. Curarine 7.5 mg. was then given subcutaneously and oxygen continuously by a short nasal tube. Relaxation occurred 30 minutes subsequently, but the patient never recovered consciousness after the previous respiratory spasm and died an hour later.

Death from generalised spasm involving respiration is one of the common ends in cases of tetanus. But in animals curarine had itself shown a tendency to cause respiratory spasms (West, 1935). In decerebrate cats these spasms can be prevented by atropine and removed by adrenaline. The means of their production is not clear, for though an isolated strip of the tracheal muscle of the cat will contract under the influence of curarine, it does so uncertainly and only with the drug in high concentration (1:1700). Such contractions of the isolated tracheal muscle are relaxed by adrenaline (1:125,000), but not by atropine.

Control Observations

In order to ascertain the therapeutic effect of curarine on the rigidity of post-encephalitic parkinsonism, three advanced cases were treated with the drug by the intravenous route.

CASE 11.—After the effects of ascending doses had been tried, the first patient received 0.25 mg. per kg. in 10 c.cm. of solution during 11 minutes by intravenous injection. Blurred vision and slight headache occurred, but there was no loss of rigidity or of tremor, both of which were marked features of the case. The result confirmed previous observations with curarine given subcutaneously (West, 1935). No respiratory symptoms developed.

CASE 12.—The second patient received intravenous curarine by the drip method; an induction with 0.1 mg. per kg. in 5 minutes (1.2 mg. per kg. per hour) resulting in a temporary reduction of rigidity. The rate of inflow was halved after 5 minutes and continued at about 0.6 mg. per kg. per hour for 10 minutes. Severe ptosis developed, the pathological rigidity relaxed, probably with some loss of power, and respiration became purely abdominal. The curarine inflow was then stopped, but restarted 10 minutes later. Rigidity returned very quickly after cessation of the curarine inflow. No laryngeal spasm occurred. The case shows that, even with the best conditions—a dripping inflow giving a gradual and controlled rise of concentration in the blood stream—the power of removing rigidity is transitory and the margin between the effective and the asphyxial concentrations small.

CASE 13.—The third patient was very rigid, with a good deal of added tremor. A preliminary injection of atropine gr. 1/50 was given; the patient having already considerable tolerance to drugs of this series. Curarine induction occupied 20 minutes and was continued until the arms were relaxed, the tremor being somewhat diminished. The flow was then interrupted for 5 minutes, after which stiffness was again increasing. Curarisation was continued at about 0.8 mg. per hour until ptosis developed (3 minutes), the patient felt unable to raise the arm (5 minutes), and breathing became "light"—i.e., abdominal (10 minutes). Parkinsonian rigidity was virtually abolished, and tremor remained nowhere but in the lips. This level of curarisation was maintained for 15 minutes at a rate of 0.2 mg. per kg. per hour, when the inflow was stopped. An hour later the patient had had a meal and the rigidity had largely returned. Curarisation was now induced more rapidly, at over 3 mg. per kg. per hour. Relaxation and "light" breathing occurred after 8 minutes and the inflow was stopped. Immediately subsequently the patient pointed to her throat, choked, and was apparently unable to breathe further. The condition closely resembled what has been described in animals under curarine (*loc. cit.*). An electric laryngoscope was instantly inserted into the mouth, and the endotracheal catheter passed, with some difficulty, owing to a spasm of the false vocal cords. A stream of oxygen was blown through the catheter, which was not removed for nearly half an hour, when its presence appeared to embarrass the patient. After the catheter had been passed, adrenaline and later strychnine were given hypodermically. The patient was able to talk 50 minutes after the onset of the spasm. She recollected no events between its commencement and the manipulation of an airway after the removal of the oxygen catheter. Sore-throat and some bronchial catarrh developed on the following day, but the patient was able to get up on the third day. She declared her rigidity to be less than previously, but if this were so it did not remain so.

The alarming experience of this "control" case demonstrates the reality of the danger of curarine respiratory spasm.

Conclusions

(1) Curarine treatment of tetanus should still be reserved for cases which are already very severe or in which by the accepted criteria (Cole, 1935) the prognosis is very grave. I have not yet had experience of a case of tetanus which showed its first symptom less than seven days after infection, and which subsequently recovered. Cole (1935) records one such case, with recovery under antitoxin and general treatment only. But cases occurring on the seventh day have recovered with and without curare.

(2) If curarine be given in severe tetanus, the intravenous drip is probably the most effective method of its administration.

(3) A real danger of curarine treatment—bronchial spasm—is shown by the experience with a "control" case of advanced parkinsonism (Case 13). The

spasm can be effectively treated by prompt endotracheal intubation only. Probably the risk of it is increased if the induction of curarisation is hastened beyond the rate of 1.5 mg. per kg. per hour (or 0.25 mg. per kg. in ten minutes). Animal experiments justify the administration of atropine gr. 1/100–1/50 hypodermically before and at four-hour intervals during the period of curarisation, and of a full dose of adrenaline (1 c.cm. liquor adrenalini hydrochlor.)* if the spasm occurs.

(4) Curarine in its present available form is unsuitable for the treatment of cases of chronic rigidity.

(5) Curarine is given to cases of tetanus only as a means of removing muscular spasm. It may be combined with other methods of treatment, particularly with *light* avertin narcosis. Needless to say antitoxin is required as urgently as with any other treatment. At present I would give 200,000 units when the diagnosis is made. This is the recommendation of Cole in his recent full review of the treatment of tetanus (1935). In the early and acute cases, if the patient can be kept alive for two days, the giving of more serum should be considered. I should like to endorse Cole's plea for early diagnosis: "Stiffness of the jaw, especially if accompanied by pain in the back or abdomen, probably means tetanus."

Summary

(1) The administration of curarine by continuous intravenous drip is described.

(2) Ten cases of tetanus are recorded, nine of which proved fatal. Treatment varied (see Table).

(3) In two fatal cases curarine was given intravenously, and in one of them death was delayed beyond the expected point. Respiratory spasm followed an inability to maintain an even curarisation after 18 hours of successful treatment.

(4) The treatment of three cases of advanced parkinsonism by the administration of curarine intravenously is recorded. The absence of an adequate margin between the rigidity-removing ("lissive") dose and that affecting respiration, together with the transitory action of curarine, renders it, in its present available form, unsuitable for the treatment of these chronic conditions.

(5) Experience with one case of parkinsonism under curarine treatment establishes bronchial spasm as a serious danger of curarine therapy in man.

(6) It is suggested that the best method of giving curarine which is at present available is by intravenous drip. This method can be controlled from minute to minute, if necessary, and enables the narrow margin between the beneficial "lissive" action and the asphyxial action on respiration to be increased. It is further suggested that the only present place for intravenous curarine in therapeutics is its continued experimental use in cases of tetanus in which, by the accepted standards (Cole, 1935), recovery cannot be expected by other means.

I am indebted to the following for permitting me to see cases of tetanus under their charge: Mr. P. H. Mitchiner, Dr. R. Harvey-Williams, Dr. W. M. Robson, Dr. Maurice Shaw, Dr. Leslie Cole, Dr. R. Grainger, and the medical superintendents of Kingston Municipal Hospital, Croydon Municipal Hospital, and West Park Mental Hospital, Epsom. I received both help with cases and suggestions for improving technique from: Dr. Maurice

* Recent animal experiments showing a spasmodic action of curarine on isolated tracheal and bronchial muscle to be immediately antagonised by adrenaline suggest that this drug should be given very slowly by the *intravenous* route until relaxation occurs.

Shaw (who suggested the intravenous route), Mr. J. Lindahl Dr. R. Woolmer, and A. Kennedy.

The research embodied in this paper was undertaken with the assistance of an expenses grant from the Medical Research Council.

A MERCURIAL (NOVURIT) SUPPOSITORY AS A DIURETIC FOR CARDIAC OEDEMA

By JOHN PARKINSON, M.D., F.R.C.P. Lond.

PHYSICIAN IN CHARGE OF THE CARDIAC DEPARTMENT
OF THE LONDON HOSPITAL; AND

WILLIAM A. R. THOMSON, M.D. Edin.

PATERSON RESEARCH SCHOLAR AND CHIEF ASSISTANT IN
THE DEPARTMENT

ORIGINALLY introduced by Zieler¹⁴ as a remedy for syphilis in 1917, Novasurol was first used as a mercurial diuretic for dropsy by Saxl and Heilig¹³ in 1920. Satisfactory as a diuretic, it proved to have the disadvantage in some patients of causing a severe diarrhoea and other toxic effects. By means of chemical modifications, Salyrgan was synthesised in 1923, and it is now clear that as a diuretic it is as potent as novasurol, and that its toxicity is negligible. A similar though not identical product known as Neptal was subsequently produced in France, and it also proved efficacious in the treatment of dropsy.

These preparations have the disadvantage of having to be administered intravenously or intramuscularly, preferably by the former route. Sloughing may result from leakage into the subcutaneous tissues, and the patient have to submit to an exceedingly painful arm for the subsequent 24-48 hours. This should seldom occur, and it can be obviated with fair certainty and with little additional trouble by diluting the contents of the phial to 10 c.cm. with sterile water or saline as recommended by Bedford.¹ Attempts have been made to administer salyrgan by mouth, but with little success. Thus Fleckseder⁶ gave it in daily doses with ammonium chloride over a period of several weeks with a meagre result. Engel and Epstein⁵ refer to rectal administration of salyrgan in 100 c.cm. water, with moderately good results.

Herrmann and his colleagues⁷ suggested that a combination of the organic mercurial diuretics and the purine bases produced a larger diuresis than either separately. Such a combination is found in a preparation with the trade name of Novurit which has been tested and found satisfactory by many workers including Popper,¹¹ Crawford and McDaniel,³ and DeGraff, Nadler, and Batterman.⁴ Novurit is a sodium salt of trimethylcyclopentandicarboxylic acid allylamidmethoxymercurichydroxide combined with theophyllin. It may be given intravenously or intramuscularly in doses of 1-2 c.cm., each c.cm. containing 0.10 g. of the mercurial salt and 0.05 g. of theophyllin.

Recently the same drug has been prepared in the form of a suppository which contains 0.5 g. of novurit in cocoa butter. Though rectal administration of a drug often has clear disadvantages compared with oral administration, an effective suppository would be a simpler method in private practice than an intravenous injection. It would be an advance in the therapeutics of congestive heart failure to be able to administer a mercurial diuretic simply and safely by this route. This paper records our short experience of the clinical action of novurit suppositories. We have been assisted throughout by Dr. Basil S. Grant to whom we are indebted.

METHODS

The problem of controls in a clinical investigation is always difficult. To take alternate patients and give to one the suppository, and to the next an intravenous mercurial diuretic the action of which is already known, has the disadvantage that no two cases of cardiac dropsy are alike. The alternative, and the method used by us, is to administer different drugs to the same patient. Of course, one disadvantage of this method is that the drug first administered is more likely to produce a diuresis than one given later when the oedema is already diminishing; but on the whole we feel that it is the better method.

Twelve consecutive cases have been so treated, all being cases of congestive heart failure with oedema, although in some the oedema was slight. Two of them are excluded from this report: one died with hemiplegia and coma a few days after admission for heart failure; the other was excluded because he had received regular doses of digitalis, and we wished to test only those free from all medication other than the diuretics under discussion. Brief summaries of the ten consecutive cases utilised for this study are as follows:—

CASE 1.—Female, aged 23. Mitral stenosis. Aortic incompetence. Normal rhythm. Failure. Two years, dyspnoea. Eight weeks, palpitation and swelling of abdomen. Three days, swelling of ankles.

On admission: Cyanosis, dyspnoea, oedema of feet and lumbar region, ascites, enlarged liver, right hydrothorax. Pulse-rate 100. Electrocardiogram, sinus tachycardia. Urine, trace of albumin. Weight 7 st. 3½ lb. (46.1 kg.).

On discharge: No evidence of oedema or hydrothorax, liver not palpable. Weight 5 st. 8½ lb. (35.7 kg.).

CASE 2.—Male, aged 60. Angina pectoris. Normal rhythm. Failure. Eight years, angina of effort. Two months, dyspnoea. Two weeks, swelling of ankles.

On admission: Dyspnoea, liver slightly enlarged. Pulse-rate 100. Blood pressure 120/95. Radioscopy, small right hydrothorax. Urine, trace of albumin.

On discharge: No evidence of oedema or hydrothorax, liver not palpable.

CASE 3.—Male, aged 59. Auricular fibrillation. Failure. One year, increasing dyspnoea, palpitation. Two weeks, swelling of ankles. Three days, jaundice.

On admission: Orthopnoea, cyanosis, jaundice. Marked oedema of ankles and lumbar region. Pulse-rate 104. Electrocardiogram, auricular fibrillation. Radioscopy, no hydrothorax. Urine, trace of albumin. Weight 9 st. 5½ lb. (59.8 kg.).

On discharge: No evidence of oedema. Weight 8 st. 4½ lb. (53.0 kg.).

CASE 4.—Female, aged 66. Hypertension. Auricular fibrillation. Failure. Several years, increasing dyspnoea. Two weeks, persistent dyspnoea and oedema of feet.

On admission: Orthopnoea, cyanosis, oedema of feet, legs, and lumbar region. Liver enlarged. Pulse-rate 90. Electrocardiogram, auricular fibrillation. Radioscopy, right hydrothorax. Urine, trace of albumin. Weight 11 st. 10½ lb. (74.8 kg.).

Response to diuretics was slow. Died in hospital three

weeks after admission. Weight (4 days before death) 10 st. 4 lb. (65.5 kg.).

CASE 5.—Male, aged 68. Hypertension. Normal rhythm. Bronchitis and emphysema. Failure. One year, dyspnoea and oedema. Six months ago, in-patient with heart failure.

On admission: Orthopnoea, gross anasarca, ascites, bilateral hydrothorax. Pulse-rate 104. Electrocardiogram, normal rhythm. Blood pressure 170/110. Urine, cloud of albumin.

On discharge: No evidence of oedema or enlargement of liver. Loss of weight, 3 st. 8 lb. (22.7 kg.) (see Chart).

CASE 6.—Male, aged 25. Mitral stenosis. Aortic incompetence. Auricular fibrillation. Failure. In-patient on three occasions during preceding year on account of failure. Three weeks, swelling of abdomen. One week, increasing dyspnoea.

On admission: Afebrile, dyspnoea, anasarca, ascites, liver enlarged. Pulse-rate 90. Electrocardiogram, auricular fibrillation. Blood pressure 140/90 approximately. Radioscopy, no hydrothorax. Urine, trace of albumin. Weight 10 st. 10½ lb. (68.4 kg.).

On discharge: No oedema. Liver not palpable. Weight 8 st. 8½ lb. (54.8 kg.).

CASE 7.—Male, aged 58. Chronic bronchitis. Angina pectoris. Normal rhythm. Failure. Ten years, "winter cough." Two months, angina pectoris, palpitation, and dyspnoea.

On admission: No orthopnoea, slight oedema of ankles. Pulse-rate 96. Electrocardiogram, normal rhythm. Blood pressure 170/80. Radioscopy, small left hydrothorax. Urine, no albumin. Weight 12 st. 11 lb. (81.4 kg.).

On discharge: No oedema or hydrothorax. Weight 11 st. 4 lb. (71.8 kg.).

CASE 8.—Female, aged 53. Chronic bronchitis. Normal rhythm. Failure. Four years, dyspnoea and oedema of ankles. "Winter cough" for many years.

On admission: Dyspnoea, slight oedema of legs. Pulse-rate 76, normal rhythm. Blood pressure 162/70. Radioscopy, no hydrothorax. Urine, no albumin. Weight 10 st. 10½ lb. (68.4 kg.).

On discharge: No oedema. Weight 10 st. 5½ lb. (66 kg.).

CASE 9.—Male, aged 65. Aortic stenosis (arterio-sclerotic). Normal rhythm. Failure. One year, dyspnoea on exertion. Four months, nocturnal dyspnoea. Two months ago, in-patient with heart failure.

On admission: Orthopnoea, oedema of legs, moderate ascites, liver enlarged to umbilicus. Pulse-rate 80. Electrocardiogram, normal rhythm, low voltage all leads. Blood pressure 110/70. Radioscopy, no hydrothorax. Urine, trace of albumin. Weight 9 st. 6 lb. (60 kg.).

On discharge: No oedema. Liver not palpable. Weight 8 st. 2½ lb. (52 kg.).

CASE 10.—Male, aged 64. Chronic bronchitis and emphysema. Normal rhythm. Failure. Several years, "winter cough." One year ago in-patient with heart failure.

On admission: Orthopnoea. Slight oedema of ankles. Liver just palpable. Pulse-rate 78. Electrocardiogram, normal rhythm. Blood pressure 130/70. Radioscopy, no hydrothorax. Urine, no albumin. Weight 9 st. 5 lb. (60 kg.).

Progress: Oedema disappeared and liver no longer palpable, but very little relief of cough. Weight 8 st. 10 lb. (55.4 kg.).

The two drugs used as controls

were salyrgan and novurit, the former because its value has now been well established, the latter in order to compare the effect of the same drug intravenously and by rectum. Both were given intravenously and never intramuscularly, salyrgan in the dose recommended by the makers, i.e., 2 c.cm. which contains 0.2 g. of the salt, and novurit also in the dose recommended, i.e., 2 c.cm. which contains 0.2 g. of the mercurial salt and 0.1 g. of the theophyllin.

No other drugs were administered if it could be avoided, excepting ammonium chloride as an adjuvant as described below. In only two cases was digitalis given during the period of observation, though naturally it was often used later. In one of these (Case 3) only 45 minims (3 c.cm.) of the tincture were given on the day of admission, three days before observations were begun. The other patient (Case 4) had severe congestive failure and auricular fibrillation, and digitalis had to be administered in view of a rising ventricular rate and increasing symptoms. Observations on the mercurial diuretics were therefore made only before digitalis was given and again in combination with digitalis when the effect of the latter on the urinary output had become stabilised.

Ammonium chloride as an adjuvant in the treatment of oedema with organic mercurial preparations has been widely adopted during the last ten years following upon the work of Rowntree, Keith, and Barrier,¹² and Keith and Whelan.⁸ There is still no agreement as to the optimum dose, and in this investigation we have given it only for the 24 or

Chart showing comparative effects of various mercurial diuretics in an illustrative case. (Case V.)

48 hours preceding the exhibition of the mercurial preparation. In most cases it was given for 48 hours—grs. 120 (8 g.) during the first 24 hours and grs. 90 (6 g.) during the second. In the few cases where it was given for 24 hours only, the dose was grs. 120 (8 g.). There is difficulty in disguising its salty taste; in this series it was prescribed with liquid extract of liquorice, as recommended by the British Pharmaceutical Codex,² but the disguise is thin. The sucking of a lemon helped to remove the unpleasant taste from the mouth in some patients.

The *method of investigation* was as follows. The patient was kept in bed and a low-salt diet was ordered from the outset with a daily fluid intake restricted to 20–30 ounces (2000–2500 c.cm.). For the first three days, or until it was evident that the urinary output was steady, no treatment beyond rest was given. Thereafter the three preparations—novurit suppositories and novurit and salyrgan intravenously—were administered as follows.

SCHEMA

- (1) Novurit suppository preceded by enema a few hours before.
- (2) Novurit suppository. Aperient two nights before.
- (3) Novurit suppository preceded by enema a few hours before. Ammonium chloride administered during previous 48 or 24 hours.
- (4) Novurit suppository. Aperient two nights before. Ammonium chloride administered during previous 24 or 48 hours.
- (5) Novurit intravenously with or without previous administration of ammonium chloride as in (3) and (4).
- (6) Salyrgan intravenously with or without previous administration of ammonium chloride as in (3) and (4).

As a general rule one of these preparations was administered every third day.

RESULTS

In no case did we fail to obtain a diuresis with each of the drugs used. The accompanying Chart has been chosen as a typical example of the results achieved. The œdema began to diminish immediately and all clinical evidence of it had disappeared as a rule within a fortnight, the exact time varying with the initial degree of œdema. Thus in Case 6 there were no clinical signs of œdema a fortnight after treatment had been begun.

An equally satisfactory result was obtained in those cases with hepatic enlargement—in every case the liver returned to normal size. In Case 9, for example, where the hepatic enlargement was much more striking than the degree of œdema, the liver was not palpable at the end of a fortnight. The table summarises the results obtained in all the cases, and there are several points to which we would draw attention. Taking, in the case of each drug, the average 24 hours urinary secretion per dose, it is seen that for the novurit suppository this is 87.2 oz. (2470 c.cm.), for novurit given intravenously 121.1 oz. (3435 c.cm.), for salyrgan 91.8 oz. (2600 c.cm.).

The onset of diuresis was more rapid and tended to be less prolonged with salyrgan than with the other two drugs. Thus with salyrgan, taking the average percentage excretion per dose, 81.7 per cent. of the diuresis occurred during the first twelve hours, while with novurit and novurit suppositories the corresponding figures were 67.1 and 68.7 per cent. respectively. Further analysis shows that in the first four hours the average percentage excretion per dose was 44.9 per cent. for salyrgan, 25.9 per cent. for novurit, and 23.2 per cent. for novurit suppositories.

Table showing the Twenty-four Hours Urinary Excretion following the Administration of Mercurial Diuretics

Average diuresis	96.7	78.5	87.2	130	110	121.1	109.7	78.5	91.8
In c.cm.	2760	2230	2470	3690	3120	3435	3110	2230	2600

The corresponding figures for the third four-hourly period were salyrgan 12.1 per cent., novurit 9.5 per cent., and novurit suppositories 14.9 per cent. Diuresis was never maintained beyond twenty-four hours.

The question as to whether it is desirable to secure evacuation of the bowels by means of an enema or an aperient was also investigated. It was found that with a preceding enema the average 24 hours urinary secretion was 98.4 oz. (2790 c.cm.), with an aperient two nights before it was 79.9 oz. (2266 c.cm.), while with neither it was 73.4 oz. (2082 c.cm.). As the numbers are so small, there is probably no statistical significance in these differences, and it may be concluded that the premedication treatment makes little difference provided there has been a satisfactory evacuation of the bowels. It was noted that several patients experienced more difficulty in retaining the suppository after an enema than after an aperient; on this account the aperient should be given two nights before the suppository, as, given

the night before, it would be more likely to leave the rectum in an irritable condition. The aperient used was liquid extract of cascara sagrada in doses of 1 fluid drachm (4 c.cm.).

With intravenous administration of the mercurial diuretics it is the general experience that the preliminary administration of the acid-forming salts results in a greater diuresis. Our figures, though small, support this belief, as in the case of novurit the diuresis with and without preliminary ammonium chloride was respectively 130 oz. (3690 c.cm.) and 110 oz. (3120 c.cm.), while for salyrgan the corresponding figures were 109.7 oz. (3110 c.cm.) and 78.5 oz. (2230 c.cm.). The results with the suppositories were similar, as with ammonium chloride the result was 96.7 oz. (2760 c.cm.), while without it the average 24 hours urinary secretion per dose was 78.5 oz. (2230 c.cm.).

No toxic or local irritative effects were observed except that in Case 1 after one suppository there was a small motion with each passage of urine, but without other upset. Further suppositories produced no such effects; nor did such effects arise in any other patient. All our patients received at least three suppositories in as many weeks (apart from successive intravenous injections), and one (Case 5) received seven within six weeks. The presence of a fissure or inflamed hæmorrhoids should doubtless be a contra-indication to their use. Occasionally the patient had difficulty in retaining the suppository, but even when it was retained for only two hours, the subsequent diuresis was satisfactory—e.g., Case 2 only retained the first suppository for two hours, yet the diuresis was 96 oz., while the second suppository, which was well retained, was only followed by a diuresis of 64 oz. In one case (5) the antecubital veins became so sclerosed that intravenous medication became difficult. This resulted in a slight leakage with the final dose of intravenous novurit. By the evening the forearm had become swollen and very tender and it did not return to its normal size until several days had elapsed. This is one of the disadvantages of intravenous administration, and is just as likely to occur with salyrgan.

DISCUSSION

Digitalis is of primary importance in the treatment of congestive heart failure. Often this is all that is required, but in a large proportion of cases some further therapy is necessary. For persistent dropsy, and even for a persistent hepatic enlargement, the organic mercurial diuretics are now the best means available.

From the results of this preliminary investigation we are not prepared to discriminate between novurit and salyrgan both given intravenously, though the Table suggests that novurit is rather more efficient. The studies of Limova,⁹ Crawford and McDaniel,³ and DeGraff, Nadler, and Batterman⁴ are in favour of novurit.

In order to obtain information concerning the unaided action of these drugs, digitalis was not given either before or with the mercurial diuretics. In practice digitalis would nearly always be given before and with these drugs, and as a result a larger diuresis would be expected.

The main reasons for preferring rectal administration by means of a suppository to intravenous medication have already been stated. Rectal administration will prove particularly useful to a practitioner who does not happen to have regular opportunities for using drugs intravenously. In addition,

there are cases where œdema of the upper extremities renders intravenous medication almost impossible. A further advantage is that the intelligent patient, under full medical supervision, should be able, if necessary, to insert the suppository himself.

The results reported here seem to indicate that as a diuretic the suppository is satisfactory, particularly in view of the fact that the degree of œdema in several members of the series was slight. The diuresis is not as great as with intravenous medication, although a larger amount of the drug is contained in the suppository than in the recommended intravenous dose, but such a finding is only to be expected in view of the smaller absorption there must be in rectal as compared with intravenous administration. Still a diuretic agent so simple to administer and which can produce a flow of 206 oz. (5840 c.cm.) in twenty-four hours and which on an average produces 87.2 oz. (2470 c.cm.) is an addition of value in the treatment of dropsy.

SUMMARY

(1) The therapeutic value of an organic mercurial diuretic which can be given as a suppository, the novurit suppository, has been investigated. This suppository, according to the manufacturers, contains 0.5 g. of novurit, a complex organic mercurial compound akin to salyrgan, but combined with 5 per cent. of theophyllin, in cocoa butter.

(2) Ten cases of congestive heart failure with œdema have been treated with this suppository and also with novurit intravenously and with salyrgan intravenously.

(3) The average twenty-four hours excretion of urine per dose was for the suppository 2470 c.cm. (87.2 oz.), for novurit intravenously 3435 c.cm. (121.1 oz.), for salyrgan intravenously 2600 c.cm. (91.8 oz.).

(4) The previous administration of ammonium chloride results in an increased diuresis with the suppository, as it also does with novurit and salyrgan intravenously.

(5) With the suppositories 68.7 per cent. of the diuresis occurred within the first twelve hours, while the corresponding figure for salyrgan intravenously was 81.7 per cent. The diuresis does not extend beyond twenty-four hours.

(6) No toxic or irritative effects of the suppository have so far been detected. Free evacuation of the bowels is desirable though not essential, and if an aperient is necessary, it should be given forty-eight hours before the suppository.

(7) It is concluded that novurit suppository is an effective and safe diuretic.

HYPERVITAMINOSIS D

BY LEWIS THATCHER, M.D., F.R.C.P. Edin.

PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK CHILDREN,
EDINBURGH; LECTURER IN CHILD LIFE AND HEALTH
IN THE UNIVERSITY OF EDINBURGH

THE case is that of a baby aged 11½ months whose health had been failing steadily for about four months without any obvious reason; he died four days after admission to hospital, when lesions characteristic of hypervitaminosis D were found in the kidneys.

CASE RECORD

Preliminary history.—In April, 1934, at the age of 4½ months, he was admitted to the Royal Edinburgh Hospital for Sick Children suffering from mild scorbic dermatitis. He was a well-nourished child, the body length being 26 in. and the weight 14 lb. 10 oz.; he had thrived well on artificial feeding, and was taking a reasonable ration of undiluted raw certified milk; he had been perfectly well except for the dermatitis that had been present for about three weeks. He was discharged cured in a fortnight, and brought up for inspection a month later, in June; he was very well, the skin was clear, and he had gained 1½ lb. to 15 lb. 14 oz.; the diet was left as it was—raw milk without any additions. He was not seen again for nearly five months, until he was readmitted to hospital on Nov. 7th, 1934.

History.—His general health had been failing since the beginning of July; he lost his good colour and was always fretful, without actual pain or fever; there was persistent anorexia, with constipation, and he had become steadily worse during the last month. He had not gained weight satisfactorily, and there had been many fluctuations between July and mid-October, when he weighed 16 lb. 10 oz.; then there was a steady loss, and on Nov. 7th he weighed only 15 lb. 13½ oz.—the same as five months before, although he had grown 2½ in. in that time. He had been well cared for, and was out of doors constantly throughout the summer; the home conditions were good, in a pleasant open part of the city; he had been given two treatments with the ultra-violet lamp in October.

The *daily diet* had been as follows. Late June and July: 35–40 oz. of raw Grade A (T.T.) milk with about 1 oz. of sugar added; ten drops of cod-liver oil thrice daily; six teaspoonfuls of orange juice; Virol, for one week only. August: as before, but the milk was cut down to about 30 oz. and one feed of oatflour porridge or some other cereal was given; strained soup and gravy and potato were given occasionally, and the yolk of an egg twice a week; feeding gradually became difficult because of loss of appetite; cod-liver oil was given regularly, and the mother sought to combat the increasing weakness and flagging weight curve by giving as much as half to one teaspoonful (1 to 2 grammes) three times on many days. During September and October the diet was very much restricted because of the persistent anorexia; less than one pint of milk was taken, with a little mixed feeding; cod-liver oil and fruit juice were given as in August, and pressed upon the unwilling child.

Extract from case notes.—He is a pale, thin, and very feeble infant, collapsed but not severely dehydrated; rectal temperature subnormal; no œdema; muscles small and very soft; cranial bones well calcified, the anterior fontanelle being of normal size; eight good teeth. The urine is scanty in amount and strongly acid; there is a trace of albumin, and no sugar or acetone; on microscopic examination of a fresh uncentrifuged specimen a few pus cells are seen—about four to the high-power field; no red blood corpuscles, and no casts after centrifuging. *Staphylococcus aureus* was cultured from the urine, but this was assumed to be a contamination because a specimen taken two days later was sterile; (post mortem, the genito-urinary tract was found to be free of pyogenic infection).

End of illness.—A diagnosis of terminal pyelonephritis was made, but no explanation could be given for the persistent failure to thrive, and for the fact that the urine

was sterile. The urine was alkalinised within 24 hours without improvement in the baby's general condition; there was irregular and increasing pyrexia, and several convulsions with a normal cerebro-spinal fluid; death took place four days after admission to hospital.

POST-MORTEM FINDINGS

A post-mortem examination was performed by Dr. Agnes Macgregor, pathologist to the hospital, who reported as follows.

The body was that of a small, thin male infant. The bones were well calcified and their ossifying junctions appeared to be normal. Apart from slight hypostatic congestion and œdema of the lungs, and mild fatty degeneration of the liver, the only significant pathological changes were in the kidneys. These were swollen, pale, and rather severely congested in a patchy fashion. On section there were found peculiar deposits of a grey granular material, very slightly gritty, which formed a narrow line along the bases of the medullary pyramids. This material could not be expressed or removed by scraping. It was present in every pyramid of both kidneys, but could not be detected elsewhere with the unaided eye. There were no foci of suppuration. The pelves and ureters were healthy.

Microscopical examination.—In certain tubules of the kidney there were deposits of a material which, both with hæmatoxylin and with von Kossa's silver nitrate method, gave staining reactions characteristic of calcium (see Figures). These were the most numerous and largest in the medulla, especially at the bases of the pyramids, but they were present also in the cortex, where they were very small. The calcium-containing material occupied the lumen of the tubules, sometimes completely filling it; in some instances cells attached to the wall of the tubule, or lying free in the lumen, were calcified. Around all the larger and some of the smaller deposits there was some proliferation of cellular fibrous tissue. In the cortex a few glomeruli contained calcium deposits, the affected tufts being swollen and the capillaries obliterated. There were some small foci of mononuclear-cell infiltration, unrelated to calcium deposits; some dilatation of groups of tubules which contained "colloid" casts; parenchymatous degeneration of the epithelium of tubules in the cortex; and slight œdema of the stroma. The arteries were healthy. No evidence of pyogenic inflammation was found. The liver showed slight fatty degeneration. Microscopical examination of lung, myocardium, stomach, spleen, lymph gland, thymus, thyroid, parathyroid, aorta, and various arteries revealed no pathological changes.

Pathological diagnosis.—The lesions in the kidneys were similar to those described in previously reported fatal cases of hypervitaminosis D in the human subject, and closely resembled those produced in animals by experimental administration of excessive quantities of vitamin D.

DISCUSSION

A clinical diagnosis of hypervitaminosis D should have been considered, for the illness resembled very closely that known to be caused by excessive doses of vitamin D and by minute amounts given to infants who are abnormally sensitive to the action of the drug. It was not realised that the baby might have been affected by the vitamin D in the cod-liver oil that had been administered daily in considerable doses throughout four summer months, augmented as it was by that contained in a full ration of fresh cow's milk and by that formed in his tissues under the influence of sunshine—to which he had been exposed a great deal throughout the summer. In addition, he had been given two treatments with the ultra-violet lamp about three weeks before he died; these were not persevered with because irradiation did not seem to suit him. No other cause for his illness was found either before or after death, for the infection of the urine did not indicate a severe infection of the urinary tract. It is known that

he was perfectly well and thriving satisfactorily without any signs of rickets just before the institution of the intensive antirachitic régime that was carried out without remission from June to the end of October.

In 1924 A. F. Hess¹ and also Steenbock and Nelson² discovered that ergosterol was endowed with anti-rachitic properties by exposure to the rays of an ultra-violet lamp, and it was proved that this was due to the formation of vitamin D. More recently the pure vitamin was isolated in crystalline form from this preparation,³ and given the name of calciferol; its potency is about 40,000 international units of vitamin D in a milligramme, whereas a good sample of cod-liver oil contains only about 100 per gramme.

Very soon after the introduction into the practice of medicine of preparations containing irradiated ergosterol reports of its toxicity in certain circumstances began to appear. Experimentally Pfannenstiel⁴ found that a dose 100 times greater, than the minimum antirachitic one did not produce any recognisable effect on rats; one 1000 greater was definitely harmful when taken over long periods of time; and one 10,000 greater was strongly toxic. Moreover, it was recognised that these ill-effects are exaggerated when the diet is modified in certain ways (especially when it is insufficient or badly balanced), that young and non-rachitic animals have less tolerance than those that are mature or rickety, and that there is a conspicuous difference in the susceptibility of different species as well as a possibility of individual idiosyncrasy. It is important to note that animals may recover very quickly if the drug is withheld in reasonable time. There is abundant evidence that infants also may react badly

FIG. 3.—Calcified masses of one of the larger deposits showing calcified masses in tubules and slight fibrosis. Hæmatoxylin and eosin. (× 160.)

is abnormal (fretfulness with a strange apathy); there is neither pain nor fever; the weight is likely to be stationary for some time, followed by a steady decline; albuminuria and pyuria seem to be found constantly in the later stages; there may be a rise in the amount of inorganic blood phosphate without a corresponding hypercalcæmia.

The post-mortem findings are conclusive, for they are pathognomonic of hypervitaminosis D. We do not know of any other agent, or any disease, that will cause the characteristic deposition of calcium salts in the tissues; it is found always in animals that

have been poisoned with vitamin D, and is most abundant in the kidneys and urinary passages—where there may be calculi—and in the walls of the great arteries. The state of the kidneys in the case reported in this paper is similar to that described in the two other cases of hypervitaminosis D affecting babies in which the diagnosis was established by careful post-mortem examination^{11 12}; calcification of other tissues has not been seen in the human subject.

FIG. 1.—Section through base of pyramid showing calcium deposits. von Kossa's stain. (× 35.)

FIG. 2.—Calcium deposits in tubules at base of medullary pyramid. Hæmatoxylin and eosin. (× 75.)

to "safe" doses^{5 6}; there may be a true idiosyncrasy. It has been found that undue susceptibility is most common in premature or feeble infants, and in those that are not rickety; in addition, tolerance may be lowered by feeble illness and by exposure to the rays of the sun and of the ultra-violet lamp.⁷⁻¹⁰

The indications that vitamin D is exerting a toxic influence may be summarised as follows. There is failure of general health without obvious cause, and progressive asthenia is associated with marked atony of the muscles; persistent anorexia is a striking feature; there may be vomiting and slight diarrhœa at first, followed by constipation; the mental state

I can find the record of one case only in which fatal illness may have been caused by the vitamin D contained in cod-liver oil.

Malmberg,¹³ following the work of Agduhr and other Scandinavian workers, reported the case of an infant one week old who was given half a teaspoonful of the oil daily. It disagreed, causing vomiting that ceased immediately the oil was withheld; it was given again about a fortnight later in half a teaspoonful dose twice a day; this was increased soon to a teaspoonful at the same times, and was continued in this amount until the baby died when she was 4 months old. The diet was human milk, fruit juice, and a little butter gruel occasionally. There had been inexplicable failure of health for several weeks before

death; the weight was stationary, but loss was obscured by the presence of subcutaneous œdema; there was neither vomiting nor diarrhoea; the state of the urine was not described. Post mortem, the only significant findings were degenerative changes in the myocardium and elsewhere similar to those found in experimental animals that had been given excessive amount of cod-liver oil for a long time; but the deposition of calcium in the urinary tract was not noted and, therefore, the case cannot be accepted as one of hypervitaminosis D.

It is common experience that a reasonable dose of cod-liver oil is extremely well tolerated by infants, and that digestive disturbance may be brought about by injudicious use of it. The signs, as a rule, are those of gastro-intestinal irritation with diarrhoea, and they clear up quickly when the oil is withheld, or a smaller dose given. It is conceivable that ill-effects might be brought about if intestinal peristalsis was unhurried, permitting more complete absorption, and especially in the presence of constipation that seems often to accompany vitamin-D poisoning.

It is important to know that the vitamin-D content of cod-liver oil has been definitely increased during the last few years; the monopoly that it enjoyed as an antirachitic agent was broken by the introduction of numerous well-advertised preparations containing calciferol—the potency of which is made much of—and this intensive competition had to be met. Not long ago many samples contained little or no vitamin D; now most of the oil that is sold is standardised to contain a certain number of international units per gramme. I have ascertained the certified potency of eight samples that are available on the British market; five popular brands contain about 100 international units, one has 140, one 160 (both of these are fortified by the addition of halibut oil), and one 200; the latter is a natural Norwegian oil, and was used in the case reported here.

SUMMARY

The case is that of a baby aged 11½ months known to be thriving and free of rickets just before the addition to the daily diet—at the beginning of June—of a considerable dose of cod-liver oil with an exceptionally high vitamin-D content. He had been brought up on raw cow's milk, fruit juice, and the customary amount of mixed feeding; he was out in the open air and sunshine a great deal, and had been given abundant opportunities for muscular exercise. He died early in November after an illness similar to that described as being caused by hypervitaminosis D. Post mortem, changes pathognomonic of that condition were found in the kidneys.

CONCLUSIONS

Young infants may have idiosyncrasy to the vitamin D contained in cod-liver oil as well as to artificially prepared calciferol. The present-day tendency to increase the vitamin-D potency of cod-liver oil is undesirable and unnecessary; that to which the public is accustomed, and upon which popular dosage is based—viz., about 100 international units per gramme—is sufficient for all purposes. There is no reason whatever to administer cod-liver oil to infants during the summer months when diet and hygienic conditions are satisfactory and there is no evidence of rickets.

B. AERTRYCKE FOOD POISONING

DUE TO CONTAMINATION OF FOOD WITH EXCRETA OF MICE

BY E. R. JONES, M.D. Liverp., D.P.H.

ASSISTANT CITY BACTERIOLOGIST; AND

H. D. WRIGHT, M.D., D.Sc. Edin.

PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LIVERPOOL

THE details of this small outbreak of food poisoning caused by *B. aertrycke* (*Salmonella typhi murium*) have appeared worth recording because the source of infection seems to have been definitely proved to be food contaminated with mouse faeces and also because of the impression we have formed that the completeness of the chain of evidence was due to the use of tetrathionate broth and brilliant green-eosin agar.

The outbreak involved five members of one family, living in conditions of poverty and squalor in a poor quarter of Liverpool.

The first case was a child of eight months who was admitted to Fazakerley hospital for infectious diseases on Oct. 22nd, 1935, with a large abscess in the left buttock and smaller ones in the right groin and on the dorsal surface of the left wrist. He was in a somewhat collapsed condition and suffered from diarrhoea which, the mother stated, had lasted for some days. The condition gradually became worse and the patient died on Oct. 27th. A specimen of faeces examined on Oct. 23rd yielded a heavy growth of *B. aertrycke*, largely in the group phase. At a post-mortem examination on Oct. 28th the abscess was found to be due to *Staphylococcus aureus* and was peculiar in that it contained a large mass of necrotic fat and subcutaneous tissue, about 3 in. by 1 in., lying free in the cavity. Changes in the bowel were those of slight inflammatory congestion and in the other organs those associated with toxæmia. *B. aertrycke* was isolated from the contents of the stomach, jejunum, ileum, ascending colon, and rectum, and from the spleen and heart blood. Serum collected at autopsy agglutinated salmonella group suspension in a dilution of 1 in 640 and *B. aertrycke* (type) suspension at 1 in 320.

On further inquiry it was ascertained that the father, mother, and two sisters of the dead child had all begun to suffer from diarrhoea on Oct. 24th, two days after the child had been removed to hospital. The attacks were mild and lasted in one case for one, and in the others for three days. Specimens of faeces from all four cases collected on Oct. 30th yielded cultures of *B. aertrycke*. Sera collected from three of the patients on Nov. 8th agglutinated standard suspensions as follows:—

	Salmonella group.	Aertrycke type.	Aertrycke O.
Patient A ..	1 in 20	1 in 40	Nil
„ B ..	1 in 80	1 in 40	1 in 80
„ C ..	Nil	1 in 40	1 in 80

In view of the age of the first patient (8 months) and the nature of the infection it was suspected that

milk might be the vehicle of infection and mice the source. Through the courtesy of the medical officer of health for Liverpool (Prof. W. M. Frazer) it was possible to examine six mice trapped in the house between Nov. 5th and 7th. From the intestinal contents of one of these *B. aertrycke* was isolated. The intestinal contents and spleen of the other five failed to provide cultures of this organism, as also did the spleen of the mouse whose faeces contained *B. aertrycke*.

A partly used tin of a dried milk preparation with which the child had been fed was fortunately available for examination. This was found to contain several pellets of mouse faeces of which four were examined, and from one *B. aertrycke* was isolated.

It seems reasonable to suppose that the infant was infected via the milk and that this had become infected by contamination with mouse faeces. So far as could be ascertained no other member of the family had consumed any milk and it is possible that they may have been infected from the first case. At the coroner's inquiry it was made clear that the conditions in the house and the habits of the inmates were such as to render this highly probable.

The possibility that rats or mice might be the source of infection in some outbreaks of food poisoning has been suggested by several workers, notably Bainbridge (1912) and Jordan (1931), in view of the fact that rodents are not infrequently found infected with organisms of the salmonella group under natural conditions. Most workers have found *B. enteritidis* (Gaertner) the infecting agent in rats, while in guinea-pigs and mice it is more often *B. aertrycke*. But although outbreaks have been traced by various authors (Shibayama 1907, Willfuhr and Wendtlandt 1921, Spray 1926) to the contamination of food with "rat virus" this has usually been due to direct contamination of utensils without the intervention of the mouse or rat. The only instance of association with naturally infected mice which we have been able to trace occurred in the outbreak described by Salthe and Krumwiede (1924) which appears to have been well established. Another possible case is the outbreak No. 51 in the series recorded by Savage and Bruce White (1925), though the mice in this instance were not examined until some weeks after the outbreak occurred.

We have been unable to obtain any evidence that "rat virus" was employed for rodent destruction in the neighbourhood where these cases occurred. As most of these viruses contain *B. enteritidis* (Gaertner) the infection is unlikely to have come from such a source. The house was found to be badly infested with mice and little or no effort had been made to protect food from them.

We have been interested to find that Williams, Murray, and Rundle (1910) recorded a group of seven cases of "summer diarrhoea" in Liverpool from which they isolated organisms of the salmonella group. The first of our series might easily have been so diagnosed.

The ease with which the chain of evidence has been established in this outbreak is in no small part due to the use of specially satisfactory media. These have consisted of an enrichment broth containing sodium tetrathionate prepared as described by Schäfer (1935) following Müller (1923) and an agar medium containing brilliant green and eosin described by Teague and Clurman (1916) and recommended by Meyer and Stickel (1918). We have found this combination extremely valuable in the isolation of all members of the typhoid-paratyphoid group

but apparently of no value for dysentery bacilli. Kauffmann (1930, 1935) has also reported very favourably on the employment of a modified tetrathionate broth for the investigation of intestinal infections. As these media appear to be so satisfactory we think our experience may be of interest to those engaged in the investigation of these conditions.

We wish to express our indebtedness to Prof. Frazer and his staff, especially to Dr. B. T. J. Glover, for assistance in obtaining material for examination and for data regarding the onset of the attacks, and to Dr. A. E. Hodgson for the opportunity of investigating the first case and for clinical information.

Clinical and Laboratory Notes

"MORBUS BRITANNICUS"

A FORM OF FIREMAN'S CRAMP

By Sv. E. KOFOED, M.D.

MORBUS BRITANNICUS is the name we have given a special sort of fireman's cramp, seen very often among the sailors of British trawlers coming to the Faroe Islands. It is never seen among Scandinavian sailors. In the "Ship Captain's Medical Guide" (London, 1929), by D. D. F. Macintyre, the disease is described as follows:—

"Firemen are peculiarly liable to a severe form of cramp, which affects the muscles of the belly, arms, and legs. The patient is usually discovered groaning and writhing on the deck, with his extremities curved, in excruciating pain, and his muscles drawn into hard rigid knots. . . . There may be frequent watery stools and signs of collapse. . . . The complaint is specially prevalent after leaving home ports, and decreases when well in blue water. . . . It attacks men who drink large quantities of cold water when the body is overheated. . . . Treatment: As the condition is due to deficiency of salt in the system, the treatment should be directed towards rectifying this deficiency. A pinch of salt should be put in every drink the men take in the stokehold. A hot salt-water bath will afford speedy relief. In bad cases an enema of warm salt solution—a teaspoonful of salt to the pint of water—may be given. . . . Other treatment is to rub the affected parts with turpentine liniment and to give a dose of cramp mixture, which may be repeated in half an hour if necessary."

The picture of the illness we have seen in the Faroe Islands, and which we have given the name of morbus Britannicus, is not quite identical with the one given by Macintyre, but there are so many points of similarity that we conclude that it must be fireman's cramp. Of the 30 patients in whom we have made this diagnosis, 10 were firemen, 6 trimmers, 3 engineers, and 5 cooks, and 6 had other occupations. Eleven were less than thirty years old, 11 between thirty and forty, and 8 more than forty.

The symptoms include headache, abdominal pain, and constipation—sometimes diarrhoea, but more

frequently constipation, which must be emphasised as a feature differing from the above description. Further were observed nausea, vomiting, and pain in the muscles of the belly, arms, and legs. The pain is often very alarming and spasmodic; only seldom have we seen generalised tonic and clonic spasms—namely, in cases when the disease has lasted a very long time, or where there was complicating organic stenosis of the pylorus. There have been only 5 cases with generalised spasm.

We have not seen fever. The pulse is ordinarily normal, in some cases a little more rapid than usual. The patients are pale, shocked, and apathetic. The spasm of the belly can be so intense that it looks like a regular pseudo-defence. This we have seen in 10 cases. It is therefore easy to understand that the diagnosis may be difficult, because the question of ulcer, cholelithiasis, or appendicitis arises. The patients may be suffering from terrible pain and the muscles iron-hard. The abdomen is boat-like, retracted, and diffusely painful. The spasm takes all the muscles of the abdomen more specially the recti abdominis. Therefore one considers first of all the possibility of a perforation with consequent peritonitis; but the picture is usually less violent, there is less shock, and pulse and temperature are not affected. Also flatus is usually free. Nevertheless we have in 3 cases very nearly diagnosed appendicitis, in 1 case cholelithiasis, and in 2 cases gastric ulcer.

In such doubtful cases it generally suffices to observe the patient carefully for some hours and give a small glycerin enema. Then we see opening of the bowels, and the patient will pick up. If one thinks of the possibility of fireman's cramp one is almost sure to get information about pain in the muscles of the arms and legs and find tetanic and rigid muscles.

We have the impression that the abdominal spasm comes first, perhaps because there is constipation. Another question is connexion with sea-sickness. We have no doubt that this is often present and partly causes the headache, nausea, and vomiting. Fireman's cramp is due to loss of salt by sweat, and naturally this is aggravated by sea-sickness, where there is loss of chlorine ions by vomiting, which in itself can lead to gastric spasm.

We have also seen cases of *ulcus ventriculi* complicated with morbus Britannicus. In one of these there was a violent spasm of pylorus accompanied by universal tonic spasm. The very ill patient was most strikingly relieved by two intravenous injections of 5 c.c.m. 10 per cent. of calcium chloride. Later a radiogram showed great dilatation of the stomach due to a duodenal ulcer. The other patient had a less violent attack of spasm. After the attack we discovered distinct symptoms of a stenosing ulceration of the stomach, and he was operated upon by a retrocolic posterior gastro-enterostomy. Since then he has been well and he is now cook in a trawler.

Remembering Prof. J. S. Haldane's researches into "miner's cramp," we have looked for chlorides in the urine. These were never completely absent, but the reaction was very weak in spite of the small diuresis. We have not yet been able to make quantitative researches on the chlorides in urine and blood, but we intend to do so in future. In our cases it seems that the amount of chlorine is more important than the amount of sodium chloride, and we have seen good results from calcium chloride per os, per rectum, or intravenously. Experienced captains believe that starvation and excesses are predisposing causes; also previous diseases. We have seen a case of morbus Britannicus occurring just after a bad

attack of malaria, and this was in a trimmer forty years of age who had been at sea for many years all over the world. As a direct cause bad weather is almost always observed.

We have never seen this disease among the fishermen of the Faroe Islands, and I think this is due to the salt food of these men. Sea-sickness is the same for British and other sailors, and so cannot be the cause of the prevalence among British sailors.

Morbus Britannicus is rather an important disease on British ships, which is proved by the fact that we in Klaksvig (in the northern part of the Faroe Islands) in the last three years have treated 180 British sailors, of whom 30 were suffering from this disease. We shall therefore conclude by suggesting that salt meat should be introduced as a part of the food on British ships, because this has proved to be preventive against the illness on Scandinavian ships. The treatment recommended in the "Ship Captain's Medical Guide" has not been effective, because the men are sea-sick at the same time and vomit the salt drink recommended, and usually do not trust themselves to give enemas. Prevention is most certainly in these cases best.

SEVERE SYPHILITIC ANÆMIA OF THE PERNICIOUS TYPE

BY CHARLES R. BOX, M.D., F.R.C.P. Lond.,
F.R.C.S. Eng.

CONSULTING PHYSICIAN TO ST. THOMAS'S HOSPITAL,
LONDON; AND

A. MORTON GILL, M.D. Lond.

SYPHILIS is a common disease and pernicious anæmia by no means rare, and yet the combination of the two diseases in the same patient is not often seen. In cases of severe anæmia with a positive Wassermann reaction it is usual to follow Stokes's classification¹ which is as follows:—

- (1) True pernicious anæmia with a false positive Wassermann reaction.
- (2) True pernicious anæmia in association with syphilis.
- (3) Severe anæmia due to syphilis.

We believe that the following case belongs to the third group, and we have therefore endeavoured to trace any previous case, clinically and hæmatologically resembling pernicious anæmia, with a positive Wassermann reaction showing no response to stomach extract, but restored to normal by antisppecific measures only. We have been unable to find any record of such a case.

In the days before liver and stomach extract therapy, Labbé² in 1906 reported a case of severe anæmia in a syphilitic which failed to respond to iron but was cured by mercury; Nathan³ in 1914 reported a case of pernicious anæmia and syphilis cured by antisppecific measures only; while Naegeli⁴ had a case of pernicious anæmia and tertiary syphilis which responded to arsenic and mercury, in 1893, and was well when seen in 1918. Since the introduction of liver by Minot and Murphy, de Lillo⁵ has reported a case of pernicious anæmia and syphilis, cured by antisppecific measures only, but the effect of liver or stomach extract was not tried. The following case, therefore, appeared to us to be of interest:—

History.—The patient, a man aged 48, was admitted to the Royal Masonic Hospital on Oct. 14th, 1934,

	1934.							1935.

complaining of nasal catarrh of some ten months' duration. On admission his pallor was such a striking feature that it was apparent that there was something more seriously amiss than nasal catarrh, and, on being questioned, he admitted that he also suffered from dyspnoea on slight exertion, palpitations, giddiness, and feelings of pins and needles in both arms and legs. His occupation was that of an accountant, and he had a wife and family, all in good health.

Examination.—The mucous membranes were pale and the patient had a bilateral malar flush. He was somewhat thin, his weight being 8 st. 9 lb. 7 oz. His tongue was smooth with atrophy of the papillae, his teeth false. The heart was clinically slightly enlarged to the left, and a loud blowing systolic murmur was audible in all areas; the blood pressure was 140/70 mm. Hg; examination of the optic fundi revealed much pulsation in the retinal veins, together with the presence of opaque nerve-fibres on both sides. The liver and spleen were both palpable. No abnormal physical signs were detected in the respiratory or central nervous systems, and examination of the urine was negative. The patient also presented a rash, and this was seen by Dr. A. C. Roxburgh who reported as follows: "Psoriasiform shiny scaly papules elbows and backs of hands. Peeling areas both palms."

Response to treatment.—Clinically the case was one of pernicious anaemia and the patient was placed on adequate doses of stomach extract by mouth. He was also given a mercurial ointment to be applied to the areas affected by the rash. A blood count and fractional test-meal appeared to confirm the diagnosis, as the laboratory reports show.

On Oct. 25th he complained for the first time of nausea with abdominal discomfort, and in view of the absence of free hydrochloric acid as shown in the test-meal, he was given a mixture containing pepsin and dilute hydrochloric acid at meal-times. There was no clinical improvement in his condition, so that we were not unduly surprised when a blood count on Oct. 30th also failed to reveal any progress. On this date he was again seen by Dr. Roxburgh, who made a note that the psoriasiform patches had almost disappeared. The fact that a rash, affecting both palms, had rapidly improved on an ointment containing mercury seemed suspicious, and on the same day a blood Wassermann reaction was done and found to be strongly positive. We thereupon decided to try the effect of antispecific measures alone. All previous therapeutic measures were abandoned and the patient was placed on a mixture containing pot. iod., grs. 10, and liq. hydrarg. perchlor., ℥ 30 t.d.s., p.c. The next blood count, a fortnight later, showed a 100 per cent. improvement, and the dose of potassium iodide was increased to grs. 15 and of liq. hydrarg. perchlor. to ℥ 45. The next count, on Nov. 30th, showed no improvement, and the dosage of potassium iodide was increased to grs. 20 and the liq. hydrarg. perchlor. to ℥ 60. On Dec. 6th the blood count had again improved, the red cells having increased by nearly half a million, and on Dec. 13th, although the red cells were approximately the same, the hæmoglobin had risen by 8 per cent.

The next blood count was disappointing, and so intravenous N.A.B. (nearsphenamine) was begun, the first dose of 0.6 g. being given on Dec. 21st. This was given at weekly intervals while the patient remained in hospital,

with a steady improvement in the blood picture. The patient's general condition also improved enormously; all his symptoms disappeared, including profuse night sweats, concerning which he had complained bitterly, and he was discharged on Feb. 11th, 1935, having gained over a stone in weight since admission.

On May 30th he was readmitted to hospital for estimation of progress. Since his discharge from hospital he had returned to business and had been taking Hutchinson's pill, 2 t.d.s., p.c. Apart from this, he had had no treatment since leaving hospital. He looked and felt a new man, and a blood count on May 31st was normal with the exception of a rather high colour-index. After a further test-meal, and a blood Wassermann reaction which proved to be still positive, he returned home on June 2nd. Five more N.A.B. injections were given in June and July, and in a letter written in December he states that his health is excellent. He continues to take Hutchinson's pills.

Laboratory investigations.—Fractional test-meals on Oct. 18th, 1934, Jan. 24th, Feb. 8th, and June 1st, 1935, all showed a complete absence of free hydrochloric acid and a very low total acid curve. Blood Wassermann tests on Oct. 29th, 1934, Jan. 23rd and May 31st, 1935, were all strongly positive. The blood counts are set out in the accompanying Table.

DISCUSSION

A case is described presenting symptoms, signs, and blood picture closely resembling Addisonian pernicious anaemia with, in addition, syphilis; the disease failed to respond to adequate doses of stomach extract, but showed a gratifying improvement under antisiphilitic measures only. We cannot believe that this was a natural remission, unconnected with the therapeutic measures adopted; the improvement both in the general condition and in the blood picture was so steadily progressive, particularly after the administration of N.A.B. was begun, that we feel no doubt that the one was intimately connected with the other.

There remains the problem as to the site of the lesion. Had this been a syphilitic gastritis, causing atrophy of the pyloric and fundus glands (as was suggested by the fractional test-meals), then one would have expected a response to stomach extract, which supplies both hæmopoietin and the anti-anæmic principle. Whether a syphilitic lesion elsewhere in the gastro-intestinal tract could interfere with the absorption of the anti-anæmic principle seems to us problematical. There remain two other possibilities: either that a syphilitic lesion in the liver prevented storage of the anti-anæmic principle (cf. pernicious anaemia in hepatic cirrhosis) or that the bone-marrow was affected in some way by the spirochæte, so that normal formation of the red cells was prevented.

Our thanks are due to Dr. Roxburgh for his reports on the skin condition, to Dr. J. Bamforth for the last

three blood counts, and to Dr. Eastes's laboratory for all the other pathological investigations.

THE SYNDROME OF CROCODILE TEARS

BY I. A. TUMARKIN, M.B. Liverp., F.R.C.S. Edin.

HON. AURIST TO THE BOOTLE HOSPITAL

INCOMPLETE recovery after Bell's palsy occurs in about a fifth of the cases observed, and these may be afflicted in a variety of ways. One of the most interesting, and incidentally most distressing, is the syndrome of crocodile tears.

Briefly, this consists of a troublesome epiphora which occurs during mastication. This is to be distinguished from the epiphora which occurs in the early stage of most facial palsies, and which is, of course, due to the paralysis of the orbicularis palpebrarum. The crocodile tears appear late, even in the presence of an active orbicularis, and although some epiphora may or may not be produced by exposure to wind and so on, yet the really copious flow is only excited by the act of mastication. In a severe case the patient is constantly mopping his eye during a meal, and may indeed develop a secondary blepharitis.

Considering the comparative frequency of this syndrome, it is surprising that it should have received such scant attention. In a recent investigation,¹ I found, in confirmation of A. B. Duel's figures, that fully 20 per cent. of Bell's palsy do not recover completely. Out of these incomplete recoveries, no less than 80 per cent. (15 out of 18) showed crocodile tears to a greater or less extent. Three certainly complained bitterly of it.

Theory of causation.—This syndrome is interesting in connexion with the associated movement often seen even in patients who regard themselves as cured. Such a patient is unable to contract one set of muscles without throwing other sets into action. When told to close the eye, he also unconsciously contracts the mouth or nose muscles. This is not to be attributed to spasm or hypersensitivity of the muscles, or to some overflow of energy in the facial nucleus. A much simpler explanation is available as follows: the nerve having undergone degeneration, new axons are pushing their way out seeking their various destinations. Unfortunately some are diverted, and find their way to the wrong muscle or gland. Thus, when, for instance, the nerve centre for the orbicularis palpebrarum goes into action, some of its energy output is carried via aberrant axons to other muscles. An explanation suffices for crocodile tears—i.e., that fibres intended for the parotid gland are diverted to the lacrymal so that during mastication the salivatory nucleus is also bombarding the lacrymal gland with secretomotor stimuli.

Sundry anatomical points are raised by this theory. It seems clear that the lacrymal gland is supplied by the facial nerve, and the actual path postulated is as follows: great superficial petrosal—vidian—sphenopalatine gang. Spheno-palatine nerve—sup.

maxillary division of the fifth. The latter communicates via its orbital branch with the lacrymal nerve, and so reaches the gland. I am not aware of any explanation for this fantastic course, but there seems no doubt that the petrosal nerve really carries lacrymatory fibres. Dandy has shown that in the anterior approach to the Gasserian ganglion, the petrosal is liable to be damaged, and that this results in diminished flow of tears.

The parotid is also supplied by the facial, via the chorda tympani, which sends a branch to the otic ganglion. This disposes of the theory that the glossopharyngeal is responsible via Jacobson's nerve, the tympanic plexus, and the small superficial petrosal nerve. In point of fact, Jacobson's nerve has recently been shown to be sensory, and indeed to be the source of that particular subdivision of glossopharyngeal neuralgia known as tympanic neuralgia.

The pathological and surgical implications of this theory are of considerable importance. To begin with, it is clear that the strangulation (or whatever the lesion is in Bell's palsy) must, in these particular cases have affected the nerve where the petrosal is given off—i.e., in the region of the geniculate ganglion. Such a case would not presumably benefit from a decompression limited to the vertical portion of the Fallopian canal. It would be necessary to uncap the nerve in its paratympanic course—an operation of the utmost finesse. Again, it is possible that we may find in a lacrymatory test some quite valuable information as to the location and severity of the lesion. Whilst absence of epiphora in the early stages of a Bell's palsy might be due to a mild lesion, it is more likely to be due to a severe lesion high up enough to involve the petrosal. It should be possible to differentiate these two types. In the former case, lacrymation would still be present, *but not in the latter*. Such a test would however be complicated by the lacrymatory effect of the sympathetic, and possibly by the action of accessory lacrymal glands. Nevertheless a careful investigation of the tear flow in the various stages of facial palsy would seem to be a promising line of research.

The prognosis in crocodile tears is still doubtful. The syndrome can certainly persist for years, but I have reason to believe that it tends to diminish with the passage of time.

Treatment. if called for, is likely to prove difficult. The most likely line which occurs to me would be excision of the lacrymal gland. Apparently there are enough accessory lacrymals to prevent the development of xerosis. Alternative operations such as ligation of the lacrymal artery, or avulsion of the orbital nerve are likely to be more difficult and probably less satisfactory.

I am happy to tender thanks to the various colleagues who allowed me access to their files for the purpose of abstracting the cases on which this paper is founded.

KING EDWARD VII. HOSPITAL, WINDSOR.—Sir Gomer Berry, chairman of the hospital, and Lord Camrose have each given another £1000 towards the cost of the nurses' hostel. Their contributions, which now amount to £21,741, cover the whole cost of the hostel.

EDENBRIDGE WAR MEMORIAL HOSPITAL.—A new block for consultation clinics and additional nurses' bedrooms is to be erected at this hospital and an appeal for funds is being made. The increased accommodation is much needed and the cost of building and equipment will be about £2700.

MEDICAL SOCIETIES

LIVERPOOL MEDICAL INSTITUTION

At the December meeting of this institution, the vice-president, Mr. T. P. McMURRAY, being in the chair, Dr. R. E. ROBERTS read a paper entitled

Radiology in Obstetrics

with special reference to its dependability.

Dr. Roberts considered the various questions which might be put to the radiologist by practising obstetricians, showed with lantern illustrations the ways in which the radiologist would endeavour to answer them, and discussed briefly the reliance which might be placed on the answers. His conclusions were: (1) Radiology in obstetrics has proved to be reliable in the diagnosis of pregnancy after the sixteenth week—sometimes earlier. (2) It gives information on the position and presentation, and on multiple pregnancy or foetal abnormalities, which is more complete and reliable than that obtainable by any other diagnostic means. (3) In assessing the period of gestation where this is in doubt, radiology often gives information considerably more exact than that obtainable by clinical means. (4) Radiology, in skilful hands, gives precise help in assessing disproportion by demonstrating the size of the foetal skull and the measurements of the maternal pelvis: the application of these cephalometric and pelvimeric data is, however, outside the province of the radiologist. (5) In the diagnosis of intra-uterine death, the radiological evidence is reliable if positive; if this condition be suspected a firm negative opinion can only be given if repeated examinations are made. (6) The X ray diagnosis of extra-uterine pregnancy is reliable if direct radiology be followed where necessary by the use of contrast media. (7) In the diagnosis of placenta prævia, two methods of employing contrast media are described: (a) Radiography after the injection of uroselectan into the amniotic sac. This method is open to the objection that the injection is almost certain to induce labour, and that in the radiograms the exact site of the filling defect due to the placenta is not always readily detected. (b) Radiography after the injection of an opaque solution into the bladder and demonstration of an increased gap between the foetus and bladder in placenta prævia. This method is only reliable in the later months of pregnancy in cases of central placenta prævia where a central clot is excluded. Both these methods are in their infancy; insufficient data are available for a firm opinion as to their reliability.

In the discussion which followed, Dr. C. H. WALSH said he was pleased to note that Dr. Roberts only went so far as to claim that he could measure the pelvic brim by his special method, and thereafter leave the obstetrician to decide the mode of delivery. Dr. Walsh maintained that a radiogram of a moderate-sized hydrocephalus is extremely difficult to interpret, and that the final diagnosis rests on clinical findings. With regard to amniography, Dr. Walsh stated that after considerable experience of this method, which he instituted at Mill-road Infirmary, Liverpool, about three years ago, he had come to the conclusion that the introduction of uroselectan into the amniotic sac had a useful but limited place in obstetric diagnosis. It would outline the placental site and would demonstrate beyond doubt an abnormal foetus. The disadvantages of the method were that from the radiological standpoint only an expert radiologist

could interpret the findings, and that sooner or later labour would be induced by its application.

Dr. A. WINFIELD praised the pioneer work done by Dr. Roberts in X ray pelvimetry. Amniography, however, entailing insertion of a needle and risk of abortion, did not appear to be of much practical value, and might well shake the confidence of a patient who had only expected to have a picture taken.

Dr. F. J. BURKE said that in a series of cases he had found amniography safe and, as a diagnostic measure, accurate and helpful in the diagnosis of doubtful cases of placenta prævia. An advantage of the method was to make it possible to demonstrate abnormalities of the foetus which might not be shown by direct radiography—e.g., meningocele. This was possible because foetal soft parts as well as the bony skeleton were outlined. The method by which radio-opaque substance was injected into the bladder was not, in Dr. Burke's view, sufficiently accurate to be of real value. The diagnosis depended on a study of the distance between the posterior aspect of the bladder and the anterior aspect of the foetal skull. To obtain a view in the correct plane demanded the most careful radiographic technique. It was difficult to see how it was possible to diagnose placenta prævia in this way unless the placenta occupied the anterior part of the lower uterine segment, and was actually interposed between the maternal bladder and the foetal skull.

Mr. ST. GEORGE WILSON said that obstetricians did not need exact measurements of the bony pelvis and of the foetal head. What they needed was the foetus presenting by the head in utero at or about thirty-seven weeks, in order to decide whether the foetus would pass through. It was important to remember the factor of uterine action. With regard to the evidence of placenta prævia, he had had a little experience of sodium iodide in the bladder, and he considered it was better than the amniography method in that it did not tend to start labour. However, he recognised that it was only of use in the central and marginal types of placenta prævia. In cases where the uterus was so tense that palpation was of very little use, diagnosis by means of X rays was very valuable.

Mr. R. KENNON read a paper entitled

The Kidney from the Surgeon's Point of View

He drew attention to the large number of urinary cases so indefinite as to require the attention both of surgeon and physician; some had frequency, others hæmaturia or renal colic, which could only be explained as renal congestion or mild nephritis. That normal urine (without casts) could be excreted in the presence of advanced nephritis was evident from occasional reports upon cases of "essential hæmaturia" which had been explored. Normal urine was common in the presence of multiple renal abscesses and perinephritic abscess. Infective nephritis had been overshadowed by the milder term pyelitis on slender pathological evidence. The possibility of acute nephritis of the abdominal type required continued emphasis to avoid a dangerous laparotomy. Subnormal gall-bladder function or a normal hypertonic stomach in ill-health at 60 might be the first indication of oncoming uræmia. Mr. Kennon commented on the swing from alkalisation to the ketogenic diet and mandelic acid. Results were best when stasis was avoided. Delay to recognise when relief of tension by nephrotomy, &c., was

required produced disaster. Nephrectomy performed for essential hæmaturia, often in fear of early tuberculosis, was a serious matter. Renal carbuncle rarely called for nephrectomy. This operation carried a mortality of 7 per cent. for all types of case, and must frequently be preceded by drainage.

In the discussion which followed, Mr. COSBIE ROSS commented on the relative frequency with which cases of uræmia presented themselves as abdominal conditions, and quoted three such examples seen within a period of two years. One was admitted as a case of hæmatemesis, another as acute intestinal obstruction, and a third as pyloric obstruction. An interesting feature of the case of hæmatemesis was that the house surgeon stopped all fluids by mouth, with the result that the patient's condition became steadily worse; when the diagnosis was established, and forced diuresis instituted, rapid recovery ensued. All three cases were subsequently proved to be

uræmic. Mr. ROSS expressed his firm belief that as a means of estimating renal efficiency, the indigo-carmin test was superior to the estimation of urea in the urine collected by means of a ureteric catheter.

Dr. R. W. BROOKFIELD said that the classification of kidney disease was continually undergoing modification. The precise ætiology of many renal conditions was still obscure, and none were more baffling than those cases of undoubted renal pain which were unaccompanied by any demonstrable abnormality in kidney or ureter, and were relieved by renal sympathectomy. He thought it important that surgeons performing operations for calculus should give more than a passing thought to the possible existence of a generalised bone condition still in an early stage of development. In this connexion he referred to a patient with well-marked Paget's disease, recently seen, who had had a renal calculus removed some years earlier.

REVIEWS AND NOTICES OF BOOKS

The Parathyroids in Health and Disease

By DAVID H. SHELLING, B.Sc., M.D., The Johns Hopkins University and Hospital, Baltimore. London: Henry Kimpton. 1935. Pp. 335. 25s.

THIS is an up-to-date and accurate critical review of the anatomy, pathology, physiology, chemistry, and clinical medicine of the parathyroids. Dr. Shelling refers to the rapid progress which has been made in the past decade, especially in the chemical and clinical phases of the subject. He hopes that the monograph will appeal to the investigator as well as to the clinician, and disarms criticism by expressing his fears that the radiologist or surgeon may find the discussion on calcium and phosphorus metabolism somewhat lengthy and involved, that the chemist may find it too brief and sketchy, and that the pathologist may consider his subject neglected at the expense of chemistry or radiology. In order to compensate in part for these shortcomings a bibliography has been appended to each chapter, so that those who wish to pursue further any particular phase of the subject may know at once where to turn for the original source of information.

Under the heading Pathology of the Parathyroids variations are described in number, position, size, and weight. Quotations from six authors show that a good deal of confusion still exists on these simple matters. Dr. Shelling's descriptions and illustrations of the histology of parathyroid tumours are excellent. On this point he quotes in detail the writings of H. M. Turnbull who showed the variability of the histo-pathology of parathyroid tumours in hyperparathyroidism. Thus dark oxyphil cells, ballooned chief cells, or pale oxyphil cells may constitute the bulk of the tumour. In the discussion on the physiology of the parathyroids the effects of total parathyroidectomy and the pathogenesis of parathyroid tetany are discussed in detail. Making the most of the few recorded cases of idiopathic hypoparathyroidism Dr. Shelling quotes at length the work of W. Bauer, A. Marble, and D. Clafin on the metabolism of calcium and phosphorus in this rare condition. The biochemical effects of repeated frequent injections of the parathyroid hormone naturally receive much attention, and details are given of the effects on blood calcium, phosphorus, non-protein nitrogen, sodium chloride, and CO₂.

An illustration of the thorough method adopted throughout the work is the short section on psychosis

in tetany, in which the observations of five authors are recorded. Tetany is discussed under three headings: (1) tetany dependent upon a reduction in the total concentration or an inactivation of part of the calcium in the serum; (2) tetany due to intoxications; (3) tetany due to magnesium deprivation. Table III. gives a useful summary of the differential diagnosis of the various forms of tetany. The long section entitled Hyperparathyroidism and Osteitis Fibrosa exemplifies the good judgment of the author. He gives due consideration not only to skeletal signs and symptoms but also to the four other symptom groups which he calls general, urinary, metastatic, and metabolic. Priority is properly allocated to F. Mandl in Europe and J. C. Aub in America for appreciation of the true significance of hyperfunction of the parathyroids. The differential diagnosis of hyperparathyroidism is discussed under the headings osteomalacia, Paget's disease, renal rickets, osteoporosis, localised lesions in the bones, generalised xanthomatosis of bones, secondary carcinomatosis, leukæmia, Hodgkin's disease, erythroblastic anæmia, and osteogenesis imperfecta. In the critical review of the effects of parathyroidectomy the work of E. D. Churchill and O. Cope forms the basis for discussion. It is disappointing in this section to find such a sketchy description of the bones in generalised osteitis fibrosa; a footnote refers the reader to the work of F. von Recklinghausen and H. M. Turnbull on this subject. A whole chapter is devoted to the relation of the parathyroids to vitamin D, and the last chapter deals justly with those who misuse the parathyroid hormone in therapeutics. Useful appendices supply details as to meals of low calcium and low phosphorus content. The book is attractively printed, and the illustrations, especially those of radiograms and histological sections, are excellent.

We heartily commend this book and wish it the success it deserves.

A Textbook of Bacteriology

By THURMAN B. RICE, A.M., M.D., Professor of Bacteriology and Public Health at the Indiana University School of Medicine. London: W. B. Saunders Co., Ltd. 1935. Pp. 551. 21s.

THIS text-book covers the ground required by the average student of medicine. The author has obviously tried to present the subject in the simplest

possible fashion, and at times his search for simplicity has led him into jejune and popular methods of expression which are undesirable in a text-book. For example, such a statement as "by all means, hands should be kept out of the mouth and should be washed several times a day" may represent laudable doctrine but is best omitted from a 500-page work on bacteriology. On the whole the information given in the book is accurate, though the definition given of a unit of diphtheria antitoxin as "the amount of antitoxin that will neutralise 100 M.L.D. of freshly made diphtheria toxin" is almost enough to disqualify an author from being regarded as a serious exponent of immunology. Chapters on immunity, filtrable viruses, and protozoa give completeness to a book which, if in no way inspired, provides a serviceable enough introduction to bacteriology.

Antenatal and Postnatal Care

By FRANCIS J. BROWNE, M.D. Aberd., D.Sc., F.R.C.S. Edin., F.C.O.G., Professor of Obstetrics and Gynaecology, University of London; Director of the Obstetric Unit and Obstetric Surgeon, University College Hospital, London. London: J. and A. Churchill Ltd. 1935. Pp. 480. 15s.

His sense of the growing importance of antenatal and postnatal care and the inadequacy of its representation in obstetric literature has spurred Prof. Browne to write a book which really meets a need. He starts with a welcome account of development of antenatal care, tracing its history back for four hundred years, and then proceeds logically to consider the management of the patient from her first visit to ascertain whether or not she is pregnant. We observe that he advises a Wassermann test in every case. Prof. Browne explains what importance is attached to an accurate history of past pregnancies and labours and goes on to say that this history "is usually obtained by a senior nurse." This may be all very well in hospitals and clinics, but since the book is presumably designed for practitioners and students we suggest that in a future edition this section might with advantage be enlarged to include a note on the special points in the past history that may or may not be of significance. The paragraphs upon diet in pregnancy are suggestive, but again not sufficiently detailed. Dr. Grantley Dick Read is responsible for Chapter VI, entitled *The Influence of the Emotions upon Pregnancy and Parturition*. It is mainly concerned with parturition, and an expansion of the subject matter to fit the title would be welcome; the section on the mental outlook of the midwife is excellent.

The difficulties and pitfalls of pelvic and foetal mensuration are fully discussed and a vivid picture is drawn of the problems associated with minor degrees of disproportion. The treatment of abnormal presentations and positions is clearly set out; more attention might have been directed to the breech presentation as a possible warning of other and more dangerous complications. The chapters on antepartum hæmorrhage, the toxæmias, and the inter-relationship of pregnancy with various diseases and ailments are on sound orthodox lines.

Only 9 of the 480 pages are allotted to postnatal care; there must be a good deal more that could usefully be said on this subject by such an authority as Prof. Browne. Such subjects as the medicinal induction of labour, specialised diets, and the conduct and scope of antenatal clinics are helpfully discussed in appendices, and a large bibliography completes the work.

If occasionally emphasis seems to be laid on the detection of the abnormal, rather than on the preservation of the normal, it is because the latter aspect of antenatal work is an attitude to be cultivated rather than a discipline to be taught. Prof. Browne certainly conveys this attitude better than do most writers on antenatal care and his book should be of the greatest interest and assistance to all engaged in the practice of obstetrics.

1. Demonstrations of Physical Signs in Clinical Surgery

Fifth edition, revised. By HAMILTON BAILEY, F.R.C.S., Surgeon, Royal Northern Hospital, London. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall. 1935. Pp. 287. 21s.

2. An Introduction to Surgery

Third edition. By RUTHERFORD MORISON, M.D., F.R.C.S., Emeritus Professor of Surgery, Durham University; and CHARLES F. M. SAINT, C.B.E., M.D., F.R.C.S., Professor of Surgery, Cape Town University, S.A. Same publishers. 1935. Pp. 367. 15s.

3. The Early Diagnosis of Malignant Disease

By GEOFFREY KEYNES, M.D. Cantab., F.R.C.S. Eng., Assistant Surgeon to St. Bartholomew's Hospital; Surgeon to Mount Vernon Hospital. London: John Bale, Sons and Daniels:son, Ltd. 1935. Pp. 70. 2s. 6d.

1. This admirable book has been still further improved in its new and revised edition. It is a book which every student should read and keep by him. The steps of physical examination are clearly and simply set out and the work is beautifully illustrated.

2. A new edition of this book, originally written many years ago, will be welcomed by student and teacher alike. It fulfils well its purpose, for it supplies an introduction to surgery which can be understood by the novice to clinical work. The method of presentation is simple and effective—altogether a most satisfying work.

3. In this small book the main facts which enter into the diagnosis of malignant disease in different parts of the body are set out clearly and readably, but not in very great detail. When the reader gets over a feeling of slight surprise that its gifted author should have devoted his energies to the compilation of a collection of diagnostic paragraphs interspersed with a few illustrative clinical records he will perceive that these are presented more vividly and with greater precision than the corresponding paragraphs scattered through surgical text-books.

Praktische Anatomie

By Dr. T. VON LANZ, Professor of Anatomy in the University of Munich; and Dr. W. WACHSMUTH, Privatdozent for Surgery in the University of Bonn. Vol. I, Part III. *The Arm*. Berlin: Julius Springer. 1935. Pp. 276. R.M.26.

THE title of this book is somewhat misleading to the English reader, to whom a "practical anatomy" book is a dissection manual. The work is actually concerned with the practical application of anatomy in clinical matters. The authors start with the sound precept that anatomical knowledge is the basis of all correct physical procedure in clinical work; they have produced an interesting and fairly full account of the anatomy of the arm. We would like to see more stress laid on the function of the muscles immediately surrounding the shoulder-joint when

dislocations at this articulation are under consideration. The fact that the head of the radius is always in contact with the humerus constitutes an obstacle to the blind acceptance of the statement here made that shocks passed from the hand to the radius are transmitted by the interosseous membrane to the ulna. The illustrations are semi-schematic and clear; numerous figures representing persons turning their limbs about within hollow spheres marked longitudinally and latitudinally in degrees are of the nature of an acquired taste, but will not prevent—even if they do not encourage—an appreciative reception of this effort to serve the surgical practitioner in his work.

The Stomach and Duodenum

By GEORGE B. EUSTERMAN, M.D., F.A.C.P., and DONALD C. BALFOUR, M.D. Tor., F.A.C.S., F.R.A.C.S., and Members of the Staff, The Mayo Clinic and the Mayo Foundation for Medical Education and Research. London: W. B. Saunders Co., Ltd. 1935. Pp. 958. 45s.

THE authors of this book after surveying the ætiology and physiology of the stomach proceed to describe the useful methods of examination, and discuss the significance of symptoms and the various diseases of the stomach and duodenum. Special chapters are devoted to such subjects as anæsthesia for gastric operations and the medical treatment of inoperable cancer of the stomach, anæmia following operations on the stomach, and other complications which occur after operations on that organ or the duodenum. Chapters of great interest are devoted to such rarities as diaphragmatic hernia, hypertrophic pyloric stenosis in adults, non-malignant tumours of the duodenum, sarcoma of the stomach, and paraduodenal hernia.

The Mayo Clinic stands in the eyes of the medical world as a great surgical institution and it is perhaps scarcely just to criticise this work on the grounds that it seems to show a strong surgical bias. But as the name of Dr. Eusterman is placed first amongst the authors, and medical education and research are mentioned prominently in the early pages of the volume, the prominence throughout the book of surgery at the expense of medicine is a little disappointing. The faint enthusiasm towards medical treatment must leave the average reader with the impression that the therapeutics of every gastric disease consists in the successful application of surgery in order to terminate an illness in which medical treatment has been laudably but ineffectively applied for a considerable period. This surgical bias is to be found also in the suggestion which is made again and again that the risk of malignant change is a strong reason against the medical treatment of gastric ulcer. Thus in Chapter IV. Dr. MacCarty begins by saying that carcinoma is not only the most frequent gastric lesion but it is the most frequent form of cancer found in the human body, and proceeds to state that he has never seen a carcinoma arising from an intact mucosa and that the majority of cancers occur in association with chronic ulceration. Yet in Chapter XVI., which is devoted to the question of carcinomatous transformation of gastric ulcer, we are told that the frequency with which this change occurs is "not of primary importance," and an editorial article is quoted with approval which states "the question of the percentage of gastric ulcers becoming malignant is purely academic." The authors admit that the

majority of gastric ulcers are actually benign and will remain so, but yet produce a series of hair-raising arguments sufficient to convince the average reader that extensive resection is a wise precaution whenever an X ray reveals the presence of an ulcer in the stomach.

Even when the treatment of duodenal ulcer is under discussion we can find nothing but pessimism in the authors' outlook towards medical treatment. They admit that the information available is too slender to provide a final, authoritative answer to a question on the prognosis of duodenal ulcer treated medically. As the result of past experience they have arrived at the conclusion, "which is reflected in the attitude of life insurance companies towards patients who have ulcers," that such patients, as have not been operated on, are substandard risks. It may be comforting to the physicians who endorsed this statement that in England at any rate a man or woman with a past history of duodenal ulcer which has responded well to medical treatment for some years without relapse is more readily acceptable by life insurance companies than a patient in an equally happy condition who has undergone an operation on the stomach.

REPORTS AND ANALYSES

RUSSIAN IMPERIAL STOUT

(BARCLAY PERKINS AND CO., LTD., LONDON, S.E.)

THIS well-known stout before the war was exported to Russia. The sample which was analysed had been 21 months in bottle and had a very full and matured taste. When analysed the following results were obtained:—

Present gravity	1024.04
Alcohol by volume	10.42 per cent.
Equivalent to proof spirit	18.20 "
Matters in solution	9.66 "
These include—	
Maltose	2.53 "
Dextrin	3.22 "
Other carbohydrates, hop extract, &c.	2.41 "
Protein	0.72 "
Acidity (as lactic acid)	0.30 "
Mineral matter	0.48 "
(including phosphoric acid)	0.134 "

This stout on account of its strength and full maturity can be regarded as one of the finest products of the English brewing industry. Its condition—i.e., content of carbonic acid gas—was not excessive, and as a beverage it is most agreeable to the palate.

MONBERNO MEDICATED WINE

(PREPARED BY THE CISTERCIAN MONKS OF MOUNT ST. BERNARD ABBEY, CHARNWOOD FOREST, LEICESTERSHIRE)

This red wine has an agreeable flavour and bouquet which is suggestive of port. When analysed the following results were obtained:—

Alcohol	17.5 per cent. by volume.
Equivalent to proof spirit	30.5 "
Volatilo acidity (as acetic acid)	0.025 "
Fixed acidity (as tartaric acid)	0.42 "
Total solids	15.0 "
Consisting of—	
Sugar	12.1 "
Ash	0.46 "
Phosphoric acid	0.10 "
Meat extract	1.20 "
Other extractives	1.24 "

The claim that this wine contains meat and other extractives is supported.

THE LANCET

LONDON: SATURDAY, JANUARY 4, 1936

THE MARRIAGE OF PUBLIC HEALTH AND AGRICULTURE

THE phrase is Mr. BRUCE'S. He was speaking of the wastefulness of widespread malnutrition at a time when farmers long to produce more crops; he was pointing out that agriculture and public health have one great need in common; and he was urging the governments of the world to divert their subsidies from schemes for restricting production to schemes for enlarging consumption. Here in England this policy finds one of its best exponents in a member of our profession who is also in close touch with farming, Sir JOHN ORR of the Rowett Institute at Aberdeen. In his address to the British Association last September he admitted that price-raising methods such as quotas and tariffs have saved British agriculture from the full effects of the world economic crisis, but maintained that they can be justified only as emergency measures. At a time, he said, when there is a so-called glut of all kinds of food, the continued existence of diseases due to malnutrition shocks the public conscience, and public opinion forces an increase of the already heavy expenditure on social services in an endeavour to get them eliminated. Cheaper food would reduce the cost of such services, for it means less poverty and less disease due to poverty; and Sir JOHN went on to demonstrate that agriculture, as much as public health, stands to gain from an expansive programme. Inquiries jointly made by the Rowett Institute and the Market Supply Commission show that consumption of the "protective" foods—milk, eggs, fruit, and vegetables—rises uniformly with income, and that generally speaking it is not until we reach families with about £1 a week per person that the diet, according to modern standards, is adequate for maintaining health. At present some 20 million of the population are below this scale and if everyone in the country were brought up to the £1 5s. scale, which probably represents an optimum, the market for food would be 20 per cent. larger. He calculates that if we all had as much food as we ought the percentage increases in consumption would be: milk 42, butter 27, eggs 28, fruit and vegetables 53—which "gives an indication of the limit to which agriculture could be developed in this country without reducing imports and therefore without prejudicing our export trade or the interests of

our overseas investments." The Bishop Auckland potato experiment, in which unemployed men bought their potatoes direct from a depôt at 4d. instead of 7d. a stone, showed that there is an ample market for food at lower prices and indicated one way in which these prices can be attained. The better organisation of distribution by marketing boards could, in itself, lower retail prices, and the remaining difference between the price the public can pay and the price the farmer must charge should be made good, in Sir JOHN ORR'S opinion, by direct subsidies to these boards from the State—subsidies to be regarded as more in the interests of public health than of agriculture. "All the money going to the farmer flows back immediately to the towns, invigorates industries and reduces unemployment. None of it is lost to the country. . . The next five years should be devoted to a great constructive policy, based on increased consumption and better utilisation of our wealth, a policy designed to bring about a prosperous agriculture, a better fed people, and increased internal trade."

A voice crying in the wilderness? No. For when Mr. BOOTHBY brought forward some of these arguments in the debate on the Address last month the Government spokesman, Lord EUSTACE PERCY, took pains to show that the investigations on which Sir JOHN ORR'S conclusions are founded were made at the instance of the Government itself, and published in order to awaken public attention to the need for, and possibilities of, a policy of nutrition. Lord DE LA WARR, as Parliamentary Secretary to the Ministry of Agriculture, told the League of Nations' Assembly in September that it is not enough to resist a policy of restriction; something more positive is needed—namely, deliberate action. On Dec. 18th Lord EUSTACE PERCY, receiving a deputation from the Children's Minimum Committee, said that a broad nutrition policy must be one of the main aims of social administration in the immediate future; indeed, he went further and declared that on the main issues there was no conflict between the views of the Government and those of the deputation. If this is true it suggests a definite change of front—a determination, now that trade is recovering, to think in terms of permanent social advantage rather than the requirements of crisis. For the deputation's memorandum set out clearly their demand for a more positive approach to the problem of nutrition, their discontent with the abandoned scales of the Unemployment Assistance Board, their anxiety about the painful reports that come from distressed areas and distressed homes, and their belief that "a great deal more can be done immediately by a more generous development of existing services to safeguard and improve the health of the two sections of the community for whom proper nutrition is of supreme importance—children, and mothers during the child-bearing period." The sharpest edge of the depression, they said, is falling on families with young children, and they outlined schemes by which this national evil can at least be mitigated. Lord EUSTACE PERCY was right when he replied that

a really broad policy can hardly be based on attempts to deal merely with cases of poverty, and that its most important aim must be rather to promote the establishment of sound normal standards of nutrition and physical fitness. But he might equally well have said that such a policy must be based on the recognition that proper feeding is the first necessity for national health—a necessity more urgent and compelling even than good housing or the control of infection or any other of our hygienic aims. At present we are wasting our agricultural resources and we are wasting our human material. In Sir JOHN ORR'S words, we need a national food policy, into which both agricultural and public health interests can be fitted and reconciled.

The science of nutrition has shown the way to a more economical economy, to a more tolerable state of society. It has revealed deficiency diseases; it has described the means whereby they can and must be prevented.¹ But we shall be very much mistaken if we look on this science as merely the analysis of starvation; we should think also of the constructive contribution it may make to human progress. Dr. JAMES MCLESTER took this as his theme for the presidential address² he gave to the American and Canadian Medical Associations last summer, when he spoke of the highly significant discovery that under certain circumstances an animal's life may be greatly improved by the addition of appropriate foods to a diet previously thought satisfactory. In twenty years, he said, OSBORNE and MENDEL were able to treble the growth-rate and double the standard weight of their albino rats; they produced what was in fact a new species, simply by intelligent alteration of the rations. Can the same thing be done for man? The Chinese in Hawaii, the Japanese in San Francisco, grow larger than their compatriots in China and Japan. In this country F. G. PARSONS believes that hygiene and better food have raised the height of the upper classes, while H. H. BASHFORD reports that Post Office messengers get bigger (though not necessarily brighter) from year to year. Where must the process stop? "The mere survival of a community," Sir GOWLAND HOPKINS has remarked, "is too often taken as proof that the nutrition of its constituent individuals is adequate"; but "the community, while managing to survive, may yet be functioning at levels far below those possible to its innate capacities." In other words, MCLESTER says, adequate and optimum are not synonymous, and it may be possible, through improved nutrition alone, to bring mankind to a higher level of physical development—to a larger stature, greater vigour, increased longevity, and a higher level of cultural attainment. Ultimately this is a problem of education and of government; and the first step towards solving it is to ensure that the marriage now arranged between public health and agriculture shall shortly take place.

MORE ABOUT INFLUENZA

AN important communication by C. H. ANDREWES, P. P. LAIDLAW, and WILSON SMITH marks a further advance in our knowledge of influenza.¹ Ever since this team of workers first announced that they had succeeded in isolating a filtrable virus from cases of epidemic influenza, and advanced reasons for thinking it to be the prime cause of this disease,² their findings in subsequent outbreaks have been eagerly awaited. Would it prove that epidemic influenza was due to one and the same virus the world over or would more than one aetiological agent be found? And what about sporadic influenza? would this also turn out to be a virus disease? It was clear from Sir PATRICK LAIDLAW'S Linacre lecture³ that a virus, similar to those recovered from influenza in 1933, had been encountered during 1934 and 1935, but it is only now that the full details of this work have been forthcoming. The winter of 1933-34 saw little influenza in London, but from a small outbreak in March, 1934, a fresh strain of virus was isolated. The next winter, however, proved more propitious for the investigations and eight new strains were obtained, six from an outbreak amongst the troops in Dover and Shorncliffe and two from cases which occurred in London in the early months of 1935. All these new strains have been shown to be identical with those obtained in 1933.

To these findings must be added evidence coming from other parts of the world. In America T. FRANCIS,⁴ of the Rockefeller Institute, has isolated several strains of virus from cases of influenza and shown them to be the same as the English strains. Further, the Hampstead workers have had the opportunity of examining two of these American strains and of confirming the conclusion arrived at by FRANCIS. A recent paper by F. M. BURNET⁵ reports the isolation of a strain of virus from cases of epidemic influenza in Australia; this also was shown to be similar to the English ones. There is thus good reason for thinking that epidemic influenza, wherever it occurs, has the same virus for its prime cause. The causation of sporadic influenza, however, still remains unsolved. Material from 12 such cases has been examined for the presence of virus by the Hampstead team, with completely negative results; and negative also were the results obtained with nasopharyngeal washings from six cases of a type of upper respiratory infection prevalent in the Woolwich garrison in the early months of 1935 and diagnosed clinically as influenza. In the past many have doubted whether all cases labelled influenza constituted an entity and these findings tend to confirm the suspicion.

This latest paper from the National Institute for Medical Research¹ records two disappointments. Attempts were made to infect human volunteers

with the influenza virus, but without success. It should be pointed out, however, that only two volunteers were inoculated and that the authors advance very reasonable explanations for this failure, so that these negative results do not really mean very much. The second disappointment concerns the possibility of infecting mice direct from man. When about 18 months ago ANDREWES, LAIDLAW, and SMITH⁶ reported the successful inoculation of mice with ferret-passaged influenza virus, it was hoped that it would be possible to infect mice direct from man and thus bring influenza research within the reach of laboratories without facilities for keeping ferrets. Unfortunately this hope has not been realised. Human material which took readily in ferrets has regularly failed to infect mice; only after ferret-passage does the virus become infective for the mouse. A further piece of work calls for mention. WILSON SMITH⁷ has cultivated influenza virus. He tried two methods: (1) cultivation in the developing egg, which has been used successfully with a number of viruses, and (2) cultivation in a simple medium consisting of minced chick embryo tissue and Tyrode's solution. The latter method proved by far the most successful and should be of use in providing suitable material for immunisation purposes.

ARTERIAL EMBOLLECTOMY

REPORTS of arterial embolectomy by British surgeons owe their chief interest to the rarity of the operation in this country. Sweden, on the other hand, has a larger experience of it, and J. P. STRÖMBECK⁸ is able to report the late results in 61 cases in which the circulation was restored. These are the successes out of a total of 327. The investigation covers the years 1913-32 and, as it was made in 1934, at least one and a half years had elapsed since the last operation. The immediate mortality in the 327 cases was, of course, considerable, and in STRÖMBECK'S words 207 (63 per cent.) were "discharged from hospital dead." But these deaths were by no means always directly attributable to the operation, since the disease causing the embolism—most often cardiac—is often fatal in itself. Of the 37 per cent. surviving operation, 18 per cent. required subsequent amputation, while the other 19 per cent. were discharged alive, with circulation restored; and it is with these 61 cases that STRÖMBECK'S paper is chiefly concerned.

Only one of the patients was not traced. Of the others, 49 were alive after three years; 43 after five years; and 16 after ten years. At the time of the investigation 41 had already died, the cause of death in all but 2 having apparently a direct connexion with the disease originally causing the embolism. In 28 the cause of death is given as heart failure or as chronic myocarditis or cardio-sclerosis; other complications of the basic heart affection were hemiplegia, renal infarcts, cerebral thrombosis, and chronic nephritis. The after-

history of the patients also revealed a tendency to cerebral circulatory disturbances and to repeated embolism. STRÖMBECK sums up the prognosis after successful embolectomy by saying that, as regards expectation of life, it is essentially the prognosis of the underlying cardiac disease. Further inquiry into the working capacity after operation, and into the local damage to the part of the body affected, showed that the proportion of patients getting back to something like a good working capacity was definitely greater in those that lived longest. Of those who died within three years, at least 70 per cent. never got back to work, and many of them were bedridden. The local results tended to be good; small areas of necrosis, sensory disturbances, and peroneal paresis were reported in one-eighth of the cases.

Mr. GEOFFREY JEFFERSON'S paper read at the annual meeting of the British Medical Association in 1934 stimulated interest in embolectomy, and our issue of last Nov. 30th contained two records of successful operation, together with useful suggestions about technique. Mr. VICTOR RIDDELL pointed to the danger of secondary thrombosis at the site of an embolectomy, and proposed that the artery should be ligatured, above and below the incision through its wall, in cases where the collateral circulation, restored by unblocking of the lumen at the bifurcation of the vessel, appeared to be efficient. Mr. G. R. GIRDLESTONE believed that an attempt might often be made to massage the clot from its situation at the bifurcation of an artery into the less important branch—a plan which would have the advantage of avoiding injury to the intima, and so of lessening the risk of subsequent secondary thrombosis. This suggestion was also made by JEFFERSON. The importance of securing a lasting restoration of the circulation is obvious, and STRÖMBECK describes this as the only means by which we can hope to lower the present high mortality from the operation. A secondary amputation, where embolectomy fails, involves great immediate danger. The only other method available for lowering the mortality is to choose the patients who present the best operative risk, but any improvement in results thus attained is of course more apparent than real. It is clear, however, from STRÖMBECK'S valuable study of after-histories that no very cheerful prognosis is justified as regards restoration to normal life or length of survival.

CO-EDUCATION

OF the human race as a whole at least a half and probably more are co-educated, yet co-education is often spoken of as a difficult problem. It becomes a difficulty under two conditions: (1) when it is not simply a matter of boys and girls learning together, but also of spending most of their leisure together; (2) when co-education is not the usual custom of the community. In England both of these conditions are present. Co-education in day-schools is not the problem that it is in boarding-schools, and in the latter there are further complications associated with

⁶ THE LANCET, 1934, ii., 859.

⁷ Brit. Jour. Exp. Path., 1935, xvi., 508.

⁸ Acta chir. Scand., 1935, xi., 229.

the social class which sends its children to these establishments. Those whose playground is the street, those who have no special play-room at home, are in general, on account of their home experience, less likely to find co-education a personal difficulty, and their parents will in general view it with less alarm—and see fewer dangers—than those who live in an atmosphere of greater, even perhaps too great, exclusiveness.

Boarding-school co-education is in England inevitably regarded as different from ordinary schooling; the sex-segregated schools are thought of as normal, the others as a little peculiar. Under these circumstances it is difficult to exclude the atmosphere of an experimental undertaking, even though the schools in question may have been founded for a long time, because each generation of parents and teachers has to step out of the traditional groove when deciding on this type of school. Parents and staff are apt to become self-conscious regarding co-education, and self-consciousness in the face of a sexual question never helps towards clearness of judgment. The self-consciousness is attributable at least in part to the sense of danger, real or imagined, which attaches to an experimental situation, and is not perhaps quite unrelated to the self-consciousness and the heightened expectancy which precedes the contact of the sexes in later years; at any rate, there are similarities. Whatever may be the real dangers (we must not underestimate the prudence not to speak of the fears of adolescents), the imagined ones in the minds of adults sometimes assume the vividness and even the terminology of actual illicit sexual relations. In addition there is a special sociological terror, the assumption being that pleasure in associating with the opposite sex away from the guarding eye of an adult will, if indulged prematurely (i.e., before the person is economically able to support a home), lead to an insidious dissolution of *all* the standards of conduct and character acquired in the home, and is therefore destructive to the culture which it is hoped that the next generation will maintain, if need be with the same amount of effort expended by the last.

A discussion of co-education that avoids these questions, like the "straight talks" to the young, goes straight past the difficulties. The problem needs simplification, and the first step is to look directly at the psycho-sexual life of the child and adolescent. Co-education was the topic of the December (an "open") meeting of the Medical Section of the British Psychological Society, and the observations of medical psychologists were presented by Dr. LAURA HUTTON. The first fact to emerge is that there is not one but three problems of co-education, corresponding to three phases of psycho-sexual development. The first stage covers approximately the years from six to eleven, and is characterised by a relatively slight degree of sexual feelings, boys and girls tend to treat each other alike. They play and work together and don't think twice about it. The second stage is from eleven to fourteen, in it there is a

prepubertal awakening of interest, but at the same time an affectation of despising or ostentatiously avoiding the opposite sex. This contumely is not genuine and partly arises from a secret shame of sexual feelings, and a dread lest anyone should detect their presence. The scorn is a mask for anxieties which though not objective cannot be neglected. The third stage is that of puberty proper; it begins with a secret acknowledgment of the mutual attraction, but now the defensive aggressive attitude is directed not to the opposite sex as a whole, but to any special and public manifestation of the attraction. When there is an opportunity for the sexes to mix during the third phase there is a period of more rational and quiet friendships, to give place later to deeper feelings directed specially to particular individuals. To speak, therefore, of co-education without considering the changes of the psycho-sexual impulse in the pupils is likely to lead to a drift into meaningless generalities.

A recognition of these changes may illuminate also the special problems of the children in sex-segregated schools—viz., a narrowing of experience at a time when it should broaden, and a tendency to remain at one of the defensive (but normally transitory) positions already mentioned. For example, it is sometimes suggested that the sex-segregated schools are more likely to foster homosexual tendencies than the co-educational, since in the latter (if there is not overt or implicit intimidation) the pupils have opportunity for discovering their feelings for the opposite sex. Investigation shows that homosexual practices in schools do not as a rule have permanently serious consequences. There is however a less transitory kind of homosexual interest which is so deep rooted that it would not be influenced materially by the opportunity afforded by co-education. It is unwise to organise education about a particular sexual problem.

The whole matter requires more investigation; as yet a parent has no criteria to help him decide whether to choose a co-educational or sex-segregated school. The absence of criteria is partly due to the difficulty of the subject, partly to the fact that the child's schooling is one of the last and not least cherished fields for the enforcement of parental authority, and a kind of last ditch in which parental discipline puts up its vicarious fight. Education should not get too much involved in these struggles or it becomes a forcing-ground for faddism, and since there is so much for the pupil to master intellectually in these busy, brainy days it is undesirable for his school years to be burdened by emotionally toned problems of school organisation; those who think the pupils are not keen critics of educational theoreticians know nothing of the facts. So for the sake of pupils and schools alike, there is need for a clearer statement of those matters.

The medical psychologists give us another clinical observation which speaks neither for nor against co-education or sex-segregated schools, but which should do something to dispel alarmist

views as to the dangers of "tampering with education." It appears that character and a *Weltanschauung* are formed in the pre-school period; there is little need to fear that even the most experimental of schools will produce freaks in those having no strong tendency to freakishness; a good school helps the child to develop a strong interest in the people and things

(and occasionally even in "problems") which he finds around him. If the school is to be adapted to the potentialities of the child as well as to the need for continuity of culture in the community, whether the decision be ultimately in favour of co-education or sex segregation, the basis for a wise decision must be a deeper study of the psycho-sexual development of the child.

ANNOTATIONS

THE ACTION OF DUST ON THE TISSUES

It is now generally agreed that the essential process in the development of pneumoconiosis is the solution of the inhaled dust particles; the mere mechanical irritation of accumulated insoluble mineral particles is not sufficient to produce that degree of fibrosis which we associate with silicosis. This conception of the silicotic process is largely due to observations on the tissue reactions which result when silica and other minerals are introduced into other parts of the body than the lung. L. U. Gardner and D. E. Cummins¹ have used the intravenous route and have studied the behaviour of silica introduced in this way into the liver and the spleen. E. H. Kettle² observed the behaviour of dusts injected into the subcutaneous tissues, and J. W. Miller and R. R. Sayers³ investigated the results of injecting dusts into the peritoneal cavity. These observations showed fairly clearly that whereas certain dusts caused a very definite tissue reaction, others appeared practically inert, and it at once became apparent that here was a method which should make it possible to determine whether any particular dust might be expected to produce pneumoconiosis if inhaled into the lungs. In a recent publication⁴ Miller and Sayers have carried the matter still further. Using the peritoneum as their test tissue they have examined 16 different dusts and have found that they may be divided into three clear-cut groups.

In the first or absorptive group the dust was absorbed or disappeared without causing any gross visible damage; calcite, limestone, precipitated calcium carbonate, gypsum, and portland cement fell into this group. In the second or proliferative group—pure crystalline quartz (two samples) and a highly siliceous chert—the dust initiated cellular proliferation followed by fibrosis and retrograde changes. And in the third, inert group, anthracite coal (two samples), bituminous coal (two samples), hæmatite, carborundum, precipitator ash, and soapstone, the dust remained inert in the tissues, neither being absorbed nor causing gross proliferation. Microscopic examination of the lesions demonstrates the essential differences between them. In the early stages of the absorptive group reactions there is a little necrosis, possibly traumatic, but this rapidly disappears, and only a very minor degree of fibrosis results. In the proliferative group both necrosis and fibrosis tend to be progressive. In the inert group there is never any necrosis and fibrosis is always slight in amount. The authors do not refer to the secondary reactions in the associated lymph nodes to which Kettle⁵

attaches considerable importance, but from the observations accompanying their article the lesions they have produced seem to be sufficiently distinctive to justify their claims that the pneumoconiotic potentialities of a dust may be estimated by their technique in as short a period as 60 days.

ACID IN THE STOMACH

EXACTLY three years ago we commented on an aspect of acid secretion which promised to have important bearings on the causation and treatment of gastric diseases as well as of certain general disorders. About this time F. L. Apperly and M. C. Crabtree had shown that the concentration of the gastric hydrochloric acid during a fractional test-meal seems to depend on the bicarbonate content of the blood-plasma; in other words, that the secretion of acid is determined more by conditions of the blood than by what is going on inside the stomach itself. Further studies on the same lines are reported in our present issue in which Prof. Apperly continues his interesting inquiry into the significance of gastric acidity. In bringing together those causes which lead to variations in the plasma CO₂, it is seen that a number of diverse conditions have at least one common factor. For example, direct loss of carbon dioxide may be produced by the over-breathing which occurs in a hot bath, in some fevers, and at high altitudes; it may also be secondary to the formation of lactic acid after severe exercise or to the ingestion of ammonium chloride. There are records showing that in all these conditions gastric acidity is low; likewise it is said to be reduced in the anoxæmia associated with hæmorrhage. Apperly's experiments suggest a further step in his argument—namely, that anoxæmia is not the first consideration, but that hæmoglobin variations in the blood (upon which anoxæmia largely depends) may be correlated with changes in gastric acidity. Thus he goes so far as to assume that when the hæmoglobin content of the blood falls to about two-thirds of its normal value gastric acidity disappears, and in patients with post-hæmorrhagic anæmia he has found that this in fact happens. The idea that the relationship is as simple as this arouses doubts, however, as well as interesting speculations. It seems to be established that in some cases at least achlorhydria often precedes anæmia by long periods, and that some gastric abnormality is the predisposing cause of the blood changes; and though this does not exclude the possibility that in others the gastric anacidity is secondary to the anæmia, it will often be hard to find a primary cause of the initial blood changes. Further, there are undoubtedly some patients in whom the hæmoglobin in the blood is not above 50 per cent., but whose gastric acidity is little if at all below normal. But even if his conclusions are not entirely acceptable Prof. Apperly's paper is valuable because it brings once more to

¹ Amer. Jour. Path., 1933, ix., 751.

⁵ THE LANCET, 1934, i., 889.

the front the non-gastric factors in the regulation of the acidity of the stomach and emphasises the importance of thinking of the general condition of the patient with gastric disorders and not merely of diet and treatment with acids and alkalis. His demonstration of the action of warmth in reducing gastric acidity shows the importance of general measures in the management of conditions associated with hyperchlorhydria, and the well-known effect of fevers in causing anacidity may possibly explain some of the benefit that apparently follows the use of protein substances by injection in cases of peptic ulcer.

UNEXPECTED RICKETS AND SCURVY

Dr. Alan Moncrieff shocked the Physiological Society the other day with a communication entitled "rickets on a diet with adequate cod-liver oil, and scurvy on a diet containing adequate orange juice." The case-records now published¹ illustrate, as he says, difficulties in the simple ætiology assumed for the deficiency diseases. The rickety child, 17 months old, had been artificially fed from birth on a rational diet, supplemented by cod-liver oil in doses of one or two drachms daily or by "another preparation reputed to be 25 times as rich as cod-liver oil in vitamin D," of which she got 1½ drachms a day. Despite this she had all the physical and radiological signs of rickets, and also evidence of tetany (facial irritability and laryngismus stridulus); the serum calcium was 4.3 mg. per 100 c.cm. (ionic calcium 1.9) and the inorganic phosphorus 3.2. There was no evidence of renal disease or coeliac disease, and slow improvement took place under treatment with vitamin D and calcium intravenously. This is a case apparently at the opposite pole from that recorded by Dr. Thatcher on p. 20 of our present issue in which death from hypervitaminosis followed the use of cod-liver oil in doses by no means extremely large. Dr. Moncrieff's second case, moreover, is at least as remarkable, for here the patient developed typical scurvy at ten months, although he had had a good mixed diet and orange juice since birth amounting to half an orange daily for many months. In view of the apparent non-absorption of vitamin C he was given 400 mg. of ascorbic acid intravenously, after which he made a rapid recovery, and it might be interesting to know how he later responds to test doses of the vitamin. These cases are presumably to be regarded as examples of "conditioned" deficiencies, akin to the "starvation in the midst of plenty" of the sufferers from coeliac disease.

DENTAL CARIES AND DIET

A SMALL inquiry into the relation between sound teeth and diet is reported by Dr. Arthur Collett² of Oslo. Of two groups of children under school age, Group A belonged to a closed institution, while Group B consisted of children attending a nursery school but living at home. The latter group stayed at the school from 8.30 A.M. to 4 P.M. daily; their teeth were brushed there and they received a third of a litre of milk and a hot meal; but at home they were allowed plenty of sweets and soft bread, as well as fruit, vegetables, meat, and fish, and the state of their teeth was deplorable. Among 40 children between the ages of three and seven years, there were 584 holes in the teeth—i.e., 14.6 holes per child. (Every ruined or extracted tooth counted as two holes; the 42 teeth thus

classified accounted accordingly for 84 of the 584 holes.) Very different was the dental lot of the 11 children of similar age in Group A. They had 209 milk teeth and 14 permanent teeth, and only 19 holes, 16 of which were already stopped, could be found. These 19 holes were distributed among 11 teeth, and no less than 9 of the 19 belonged to one and the same child who had been admitted to the institution at the comparatively late age of 2-3 years. All the 19 holes were in the milk teeth. The contrast is evident from the fact that while the A children had only 1.7 holes per child and 0.08 holes per tooth, only 4.9 per cent. of the teeth being holed, the B children had 14.6 holes per child. The numerical difference between the two groups was the more striking when correlated with the difference in the size of the holes in the two groups, those in Group A being minute, those in Group B painfully evident. Dr. Collett traces this difference in large part to the dietary of Group A which contained hardly any sweets and included over half a litre of milk (for the older children), home-baked bread containing 50 per cent. whole meal, margarine (no butter), a dessertspoonful of cod-liver oil every day throughout the year, and plenty of vegetables and some fruit. Every meal ended with uncooked fruit or carrots. The tooth-brush and local dental hygiene were dispensed with, apart from the stopping of holes.

ANÆSTHETICS AND SHOCK

THE interrelationship of shock and anaesthesia, a matter of much practical importance, is by no means easy to determine. There is common agreement that insufficient narcosis may, on the advent of a painful nerve stimulus, lead to serious or even fatal shock. These cases are comparable with those in pre-anaesthetic days when a patient fainted or suffered fatal syncope at the first stroke of the knife. They are also comparable with that "psychic shock" which anaesthetists have learned to fear, when the disastrous stimulus is a mental or emotional one. In all these instances it is the absence of anaesthesia or much too light a dose which has made that shock possible. Sir Frederic Hewitt used to say that if consciousness is thoroughly abolished, at any rate when ether is the anaesthetic used, reflex fatal shock of this kind never occurs. At the other extreme, excessive anaesthesia through overdosage can produce a condition analogous to and hard to distinguish from surgical shock. The same effect occasionally follows an endothelial injection. There is, then, close association between insufficient anaesthesia and shock, and between excessive anaesthesia and shock. What may be termed normal anaesthesia is, however, regarded as one of the chief means of preventing shock during surgical operations. The efficiency for this purpose of various anaesthetics and certain methods of anaesthesia have been so clearly demonstrated by Crile that they are now generally accepted. At a recent discussion on surgical shock, given in our columns, one speaker is reported to have said¹ that "fluctuating depths of anaesthesia invariably cause shock." If the fluctuations are so extensive as to reach the two extremes, no doubt the statement is incontrovertible. But if as appears likely from the context, the speaker had in mind variations in anaesthesia within "normal" limits of depth, for example with the corneal reflex at one time abolished and at another allowed to return, we cannot agree with him. Variations of

¹ Jour. of Physiol., 1935, lxxxv., 26 P.

² Tidssk. f. d. Norske Lægefor., Nov. 15th, 1935, p. 1246.

¹ See THE LANCET, 1935, II., 1413.

this kind are constantly allowed in practice by good anaesthetists. During long abdominal operations narcosis is intentionally lightened throughout the period when some anastomosis or other surgical procedure is carried out on insensitive viscera. When the peritoneum has to be dealt with and the abdomen closed the anaesthesia is deepened. In this way the patient receives far less of the drug than he would if he has been kept deeply under throughout the operation, irrespective of its stage or of the sensitivity of the tissues being cut or sewn. Far from facilitating shock, variation of depth in this manner is prone to lessen the risk of shock by reducing the chance of excessive anaesthetic.

THE NEW POISONS LIST

ON New Year's Day the Home Office issued the new list of scheduled poisons, leaving four clear months for its study before the new rules come into force on May 1st. The list is divided into two parts. In Part I. are those substances the sale of which is to be restricted to authorised sellers of poisons, i.e., registered pharmacists. In Part II. are those substances which may be sold only by registered pharmacists and persons registered for the purpose under the Pharmacy and Poisons Act, 1933; this part includes various poisons commonly used for agricultural, horticultural, sanitary, and domestic purposes. The new rules impose certain additional restrictions, including, notably, regulation of the transport of poisons, prohibition of the sale to the public of certain potent medicinal poisons except upon a prescription given by a qualified medical, dental, or veterinary practitioner, and prohibition of the sale of strychnine except for medicinal purposes. Copies of the Poisons List, the Poisons Rules, and the form prescribed for application to be made to the local authority for registration for the sale of the substances in Part II. of the Poisons List may now be had from H.M. Stationery Office.

EFFECTS OF HORMONES ON THE PITUITARY

So much is written about the way in which the anterior pituitary acts on other endocrine organs that one is apt to forget that these other organs also influence the anterior pituitary. The latter is not really a "master gland," since it is in some respects subordinate to the activities of its "subjects"; it is only one of several factors in a dynamic equilibrium. Thus for some years it has been known that histological changes are produced in the anterior pituitary by castration of either male or female, and in castrated animals concurrent increases in the content and output of gonadotropic hormones have been observed. Administration of oestrin to the castrated female has been found to inhibit the histological changes, or to restore the histological picture to normal; but so far the restoration of the anterior pituitary has not been achieved with androsterone, the excretory form of the male hormone,¹ although it has been reported by Migliavacca² for a hormone preparation from urine, and by McCullagh³ for a water-soluble fraction from testes. It remains to be seen whether the recently isolated testosterone will have this effect. As regards less radical changes in the anterior pituitary, which take place without gross histological signs, evidence is rapidly accumu-

lating which bears on the reciprocal action of the anterior pituitary and the gonads and on the mechanism of the menstrual cycle. Many authors have described inhibitory effects of oestrin administration upon ovarian growth and development in the normal animal, but the results in this field are often confusing and contradictory, evidently because of wide variation in factors now recognised to be important, such as amounts and form of hormone administered, period of treatment, and the condition of the animal. As an example of recent work, in which detailed analysis of the effects has been made, we may quote Lane,⁴ who injected oestrin into infantile female rats for varying periods and then examined the pituitaries by removing them and implanting them into a second series of rats. The follicle-stimulating hormone was at first increased in amount above normal, and then inhibited, ultimately completely. Secretion of the luteinising hormone, on the other hand, seemed to be increased throughout the experiment. A stimulating effect of oestrin on the anterior pituitary has been recorded by other authors, for instance by Deanesly,⁵ who observed ovulation in pseudopregnant mice after administration of oestrin, probably as a result of appropriate enhancement of the secretion of follicle-stimulating and luteinising factors.

Dahlberg⁶ has applied the idea of a balance between oestrin and anterior pituitary hormones to explain the inhibition of ovulation in the human being after the liberation of one ovum and the continued repression of ovulation during pregnancy, though he favours the assumption of a direct antagonism in the ovary rather than the mechanism of pituitary inhibition. The experiment in support of this theory consisted in the inhibition, by injection of follicular fluid, of the ovulation normally induced in the mouse by injection of urine of pregnancy (containing prolans). Zondek failed to confirm this phenomenon with injections of oestrin, but other evidence indicated that an inhibition of this type might exist, and Dahlberg claims that the discrepancy is due to differences in the mode of administration. It is known that continual small doses are more effective than a single large dose, owing probably to the rapid destruction and excretion of the water-soluble hormone; oral administration, although the fraction absorbed is less, ensures more continuous absorption, and under these circumstances the original experiments have been confirmed. It seems, therefore, that in the pregnant woman there is enough oestrin continuously in the circulation to prevent ovulation, but not enough to injure the ovaries. When such blood is injected into a mouse in the usual pregnancy test the single dose of oestrin, quickly absorbed and quickly excreted, is not sufficient to interfere with the ovulation produced by the prolans.

Now the anterior pituitary, in spite of the multiplicity of the endocrine-stimulating functions attributed to it, has only three distinguishable types of cell—chromophobes, basophils, and acidophils—the accepted view being that the first type is a reserve or foundation cell which may develop into either of the other two. It is therefore reasonable to suppose that doses of oestrin which affect the gonadotropic activity of the anterior pituitary will have a parallel effect on the other activities if these are exercised by the same cells. Actually suppression of the

diabetogenic activity by œstrin has been demonstrated,⁷ but Shumacker and Lamont⁸ failed to find any effect of œstrin (in doses of 9 "rat units" per day) on the somatogenic, thyrotropic, adrenotropic, or even gonadotropic activities, as indicated by the changes in weight of the body and separate organs after a period of 67 days. Engel⁹ found that the effect of growth hormone on rats was not modified by the simultaneous administration of male hormone or œstrin. On the other hand, Bernhard Zondek, in a paper published in our present issue, has demonstrated that administration of massive doses of œstrin to young rats over a long period not only represses development of ovaries or testes, but has a most striking effect in inhibiting growth, reducing body-weight by as much as 43 per cent. as compared with control animals. In addition, he forecasts the publication of data showing effects on the thyrotropic and other activities of the pituitary, as well as changes in the anterior pituitary itself. Correlating these observations with the recorded result of thyroid feeding on the anterior pituitary and secondarily on the œstrous cycle of rats¹⁰ it seems that we are on the threshold of a closer understanding of the interrelationship of the anterior pituitary and the other endocrine organs, and of the manifold effects of administering a single hormone. Such understanding should lead to a yet more rational system of hormone therapy.

CARRIER LICENCES

THERE would not at first sight appear to be much of particular interest to medical men in a treatise¹¹ on "The Law Relating to Carriers' Licenses, under the Road and Traffic Act, 1933," unless indeed they wished for some strenuous intellectual exercise. The numerous full and complicated enactments from the Railway and Canal Traffic Act of 1854 to that of 1933 offer an intricate study for anyone rash enough to attempt their understanding without a training in the law. Mr. Maxwell has set out to make their principles and precepts clear to all those concerned with transport on the roads. And it is here that the doctor will find his curiosity justified if he looks into this volume; indeed, he may see a certain cause for alarm. Mr. Maxwell shows him that he is, according to the wording of the law, subject to penalties in which he could not expect to be involved by the ordinary use of his car. Here is one passage from the chapter on offences: "the conclusion can hardly be avoided that every motor car fitted with any kind of convenience for carrying the luggage or effects of passengers or any other kind of load is a goods vehicle, and that a license is required to carry anything in any motor car in connection with a business. . . ." This definition seems certain to include the car in which the doctor carries his case of drugs, his emergency outfit, his anaesthetic bag, and so on. Later on comes the more specific statement: "if an engineer needs a license to carry his tools a surgeon should need a license to carry his instruments," and the author goes on to show that the typist might need one to carry his typewriter, and

perhaps the barrister to carry his briefs. It appears that much of the drafting of the bills governing traffic is faulty, making the clear meaning of the law difficult to discern and indeed, if taken strictly, not seldom reducing the law to absurdity. Mr. Maxwell, an authority on railway law, has been impressed with the necessity of clearing up the muddle if people are to have a fair chance of evading liabilities for which they are unlikely to realise their responsibility, and his book should be of service to the many persons who become involved in litigation through incidents of road travel of one kind or another.

HEPATIC LESIONS IN CONGENITAL SYPHILIS

THE morbid anatomist nowadays sees relatively little of the lesions of acquired syphilis, at any rate in a frank and easily recognisable form; the gumma has become a rarity and even syphilitic aortitis is nothing like as common as it was. Still more uncommon are the lesions of the congenital form of the disease, for antenatal and infant welfare and venereal disease clinics are making their influence felt, not to speak of the increased vigilance in this direction of the general practitioner. Nevertheless, from time to time an unhappy infant slips through the therapeutic net and may in due course present very puzzling problems to the unwary pathologist. In a scholarly article in the recently established *Indian Journal of Venereal Diseases* (1935, i., 183) Dr. P. Ramachandra Rao discusses in detail the manifestations of congenital syphilis as seen in the liver. This organ, as he points out, is particularly liable to be affected by the disease, for the maternal blood passes directly to it through the umbilical vein and only reaches the rest of the body after it has passed through its capillaries. The intense saturation of the liver with spirochaetes, with the accompanying fine fibrosis and the development of miliary gummata, is the form of congenital syphilitic disease of the liver which is familiar to everybody. Less well recognised are the later or more chronic manifestations, for, as Dr. Rao observes, it may be impossible to demonstrate spirochaetes in them. Often enough the syphilitic nature of the lesions can only be presumed from the clinical history or the recognition of more characteristic changes elsewhere in the body. Among these more obscure hepatic lesions Dr. Rao includes chronic periportal pylephlebitis, pericholangitis, and endophlebitis of the hepatic vein, illustrating his thesis by descriptions of interesting cases occurring in the autopsy practice of the King George Hospital of Vizagapatam. A number of helpful photomicrographs are included and the value of the article is enhanced by a very complete bibliography.

USE OF MENTHOL IN CHILDHOOD

IN an annotation on the treatment of the common cold in France, published a fortnight ago, we mentioned the apparent unpopularity of menthol as a remedy. In adults toxic symptoms due to the use of this drug must be extremely rare, but as long ago as 1912, it seems, R. Leroux wrote in no uncertain terms of the danger of its use in childhood, and particularly in infancy, even when given by intranasal instillation in vaseline. He thought that it was liable to produce reflex inhibition of both respiration and cardiac action, and that its action and dangers were exactly comparable to those of chloroform anaesthesia in its early stages. It happens that Dr. Champeau has just recorded¹ severe disturbances

in a child $4\frac{1}{2}$ years old which he attributes to the ingestion of 6 mg. of menthol. Having previously suffered from adenoids, she was given three sweets, each containing 2 mg., at the onset of an upper respiratory infection. The menthol was in high concentration (1 in 100), since each sweet was only approximately 20 cg. in weight. An hour after the drug had been administered, the child suddenly appeared tired and asked to be put to bed; she then became very pale, with coldness of the extremities and cyanosis of the face. Respiration was spasmodic, and the pulse rapid and irregular, ceasing entirely for periods of several seconds during which the diaphragm was in spasmodic contraction; she also vomited. The crisis lasted in all about three-quarters of an hour, the condition improving after injection of camphorated oil. At Champeau's suggestion, the Medical Society of Evreux, at its general meeting last October, unanimously recommended that all menthol products should be clearly labelled as containing a drug for adult use and dangerous to children, and that the medical and pharmaceutical faculties should have their attention drawn to the danger of prescribing menthol in early life. We may note that Martindale and Westcott's "Extra Pharmacopœia" already contains a similar warning: "It is dangerous to apply an ointment containing menthol to the nostrils of infants, e.g., for treatment of catarrh,—may cause instant collapse." The same caution is applied to camphor.

THE HEALTH OF THE AIR FORCE

DURING the year 1934 the Royal Air Force maintained its good health and the incidence of disabilities fell, in fact, by more than 5 per cent. There was a total of 19,344 cases of sickness, an incidence of 632 per 1000 of strength which, compared with the periods 1928-33 and 1921-27, showed a decrease of 48 and 362 per 1000. This incidence equals that of 1932, which was the lowest since the reports began in 1920. The number of deaths of those invalided from the service and of venereal infections was each the lowest on record. The chief causes of disability were injury and venereal disease, respectively 77 and 9.9 per 1000. Of the 94 deaths, injury accounted for 58, and 24 of these were due to flying accidents. As in previous years, pulmonary tuberculosis and psychoneurosis were the commonest causes for invaliding 155 men out of the service. Disease and injury as causes of sickness bear the usual relation to one another, the former constituting 80.5 per cent. of the total. A notable decrease occurred in the number of cases due to influenza, respiratory disease and diseases of the skin. Though an epidemic of dysentery in Iraq produced a sharp rise to 156 cases, the incidence of malaria and sandfly fever fell to 373 and 283 respectively. After injury, the commonest cause of sickness was disease caused by infection, with diseases of the digestive system second on the list. The average duration of each case was 17 days. Expansion of the service has led to an increase in the routine work of the central medical establishment, and a study has been made of the effects of strain resulting from the rapid development of aircraft. During the year the results were published of research in the significance and treatment of heterophoria and in the relationship between body-build and functional efficiency,¹ when it was shown that overweight men were more capable of enduring both physical and mental strain than those under weight. In the pathological laboratories at

Halton there has been research into the aetiology of tonsillitis and droplet infections among the aircraft apprentices. A report of the possibility of yellow fever at places in the Sudan used for landing grounds by both the Air Force and the civil airways led to an investigation throughout the country. Serological tests proved that though yellow fever probably had been present in the past there was little risk of foreigners contracting the disease, and therefore there was no interference with the air services beyond quarantine examination and disinfection.

THE POPULATION PROBLEM IN INDIA

FROM a study of the growth of populations¹ Colonel C. A. Gill, I.M.S., has advanced the view that various population types can be differentiated, each representing a different stage of growth from "infancy" to "old age." The passage through these stages is dependent, he believes, on natural laws of populations which secure the progressive evolution of the human race. In general it appears from his argument that the stage of growth reached must govern the legislative and administrative action required for the needs of specific populations. In particular in British India, which Gill classified as in the "nascent" stage, any appreciable and continuous reduction of the birth-rate must, he asserts, place a check upon progressive evolution unless it is associated with a corresponding reduction of the death-rate. He therefore argues that any endeavour to popularise the use of contraceptives in that country would be a biological blunder.

From these views, outlined in our columns early this year,² Lieut.-Colonel A. J. H. Russell, Public Health Commissioner with the Government of India, and Prof. K. C. K. E. Raja, of the department of vital statistics and epidemiology of the All-India Institute of Hygiene and Public Health, dissent completely.³ Neither in vital statistical indices nor in the evidence relating to fecundity marshalled by such workers as Carr-Saunders do they find any support for Gill's theory of a decreasing urge of prolificity as a biological phenomenon when we pass from primitive to mature population types. It seems that the regulation of numbers has exercised the mind of man at all times and various means of achieving this regulation were present in primitive pastoral communities as well as in countries of modern civilisation. It is certainly difficult to see why we should be running counter to the purposes of nature by adopting contraception in preference to abortion and infanticide. If India, in particular, is to reach and maintain a higher standard of living the question of family limitation must, Russell and Raja urge, become one of increasing importance. The present picture they draw of her population is that of a community living at an extremely low standard and growing at a pace which is outstripping or threatening to outstrip its food-supply. Even if some allowance is made for a speedier development of her natural resources the attainment of higher standards of health and comfort, demand, they say, some retardation of the present rate of growth.

This conclusion can hardly be regarded as an overstatement. The position is frankly regarded as disturbing by such observers as Sir John Megaw whose opinion is quoted in this paper. "There is every reason to believe," he has said, "that the maximum increase which can be hoped for in the production

¹ Jour. of Hyg., 1934, xxxiv., 502.

² THE LANCET, 1935, i., 563.

³ Ind. Jour. Med. Res., 1935, xxiii., 545.

¹ THE LANCET, 1934, i., 1377 and 1399;

of the necessities of life will not keep pace with the growth of the population so that there is a prospect of a steady deterioration in the state of nutrition of the people." Does evolution really demand this high natality and the high mortality to which it must apparently lead? On another page of our present issue is set out Sir John Megaw's own answer to this question. In India, he says, a comprehensive food policy is needed to save that country from a relapse into barbarism. Educated Indian opinion already recognises this and he is hopeful of the success of a concerted national movement.

NEW YEAR HONOURS

THE decorations and dignities conferred by the King this New Year are few compared with those granted in last year's list of Birthday honours, which commemorated the Silver Jubilee. Of the five new knighthoods, Dr. Knuthsen's is a promotion in the Royal Victorian Order, two are given for services in India, and two go to surgeons of high distinction, Prof. Wilkie of Edinburgh, and Mr. Devine of Melbourne. Outside the straiter bounds of medicine we are glad to note that the list of new knights includes the name of Prof. Arthur Harden, F.R.S., biochemist and Nobel prizeman, while others closely associated with medical activities are Mr. Percival Hartley, D.Sc., director of the Department of Biological Standards, Mr. J. F. Marshall, director of the British Mosquito Control Institute at Hayling Island, and Miss Olga Nethersole, founder of the People's League of Health, all of whom are created C.B.E. Sir Gomer Berry, who receives a peerage, has been for many years an open-handed supporter of hospitals and the medical efforts associated with them. To these and to all whose names are set out on p. 60 we offer congratulations.

THE LITERATURE OF BLOOD TRANSFUSION

FIFTEEN years ago a bibliography of blood transfusion would have consisted of one to two hundred entries dealing chiefly with the early experiments on the technique. Since 1920 the subject has grown enormously and its ramifications are still spreading as the difficult subject of blood groups and reactions is slowly unravelled, and as the indications for transfusion increase. A bibliography of the whole field has now been compiled by Dr. E. Koenig¹ in Russia, and although this only covers the period 1900-33 the number of entries runs to 4323. It is improbable that even so it is complete, but it is comprehensive enough to be extremely valuable to everyone working on any aspect of the problem. The bibliography has been compiled by the Scientific Research Institute for Blood Transfusion in Leningrad and is published conjointly by the Institute and the *Vestnik Chirurгии*. The titles of the Russian, German, English, French, and Italian papers are printed in the original languages, and there are in addition German translations of the titles from Czech, Danish, Dutch, Estonian, Georgian, Hungarian, Japanese, Norwegian, Polish, Portuguese, Rumanian, Serbian, Spanish, Swedish, Ukrainian, and White-Russian sources. The whole subject has been divided into 22 sections and 77 subsections, the headings of the sections being printed in the first five languages mentioned. The book is therefore a model of what an international bibliography should

¹ International Bibliography on the Problems of Blood Transfusion and the Theory of Blood Groups, 1900-1933. By Dr. E. Koenig. Leningrad: Vestnik Chirurгии, 1935. Pp. 226. R.12 k.50.

be, and it is difficult to see how its plan could be improved. Its general accuracy can only be properly assessed by use, but it seems possible that the index of names could be made fuller; for example, one name which appears six times in the bibliography is only given two entries in the index. The compilation of the list is still proceeding, and a supplement will be published when sufficient material has accumulated. Suggestions will be welcomed by the Institute for Blood Transfusion in Leningrad.

THE second International Congress of Microbiology will be held in London from July 25th to August 1st under the presidency of Prof. J. C. G. Ledingham, F.R.S. The congress will have its headquarters at University College, and its meetings have been arranged under the following sections: general biology of micro-organisms (president, Prof. E. Gotschlich, Heidelberg); viruses and virus diseases in animals and plants (Prof. R. Doerr, Basle); bacteria and fungi in relation to disease in man, animals, and plants (Mr. E. J. Butler, F.R.S., London, and Prof. H. Zinsser, Boston); economic bacteriology, soil, dairying, and industrial microbiology (Prof. R. E. Buchanan, Iowa); medical, veterinary, and agricultural zoology and parasitology (Prof. E. Brumpt, Paris); serology and immunochemistry (Prof. K. Landsteiner, New York); microbiological chemistry and specific immunisation in the control of human and animal disease (Prof. W. H. Park, New York). The hon. general secretary for the congress is Dr. R. St. John Brooks, Lister Institute of Preventive Medicine, Chelsea Bridge-road, London, S.W. 1.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
DEC. 21ST, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2522; diphtheria, 1216; enteric fever, 14; acute pneumonia (primary or influenzal), 1073; puerperal fever, 30; puerperal pyrexia, 107; cerebro-spinal fever, 17; acute poliomyelitis, 6; acute polio-encephalitis, 1; encephalitis lethargica, 10; dysentery, 48; ophthalmia neonatorum, 72. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec. 27th was 3590, which included: Scarlet fever, 1171; diphtheria, 1204; measles, 250; whooping-cough, 399; puerperal fever, 20 mothers (plus 15 babies); encephalitis lethargica, 280; poliomyelitis, 3. At St. Margaret's Hospital there were 14 babies (plus 2 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 4 (1) from enteric fever, 39 (4) from measles, 8 (0) from scarlet fever, 20 (6) from whooping-cough, 55 (9) from diphtheria, 39 (9) from diarrhoea and enteritis under two years, and 67 (8) from influenza. The figures in parentheses are those for London itself.

Portsmouth, Manchester, and Grimsby each had 1 death from enteric fever. Liverpool reported 12 deaths from measles, Manchester 6, Bootle 3, Blackburn, St. Helens, and Stockton-on-Tees each 2. Liverpool also reported 5 deaths from whooping-cough. The deaths from diphtheria were reported from 30 great towns; 5 from Birmingham, 4 from Huddersfield, 3 each from Bradford and Sunderland. The mortality from influenza is scattered over 34 great towns, Manchester and Birmingham each reporting 6, Liverpool 5, Southampton 3, no other great town more than 2.

The number of stillbirths notified during the week was 254 (corresponding to a rate of 42 per 1000 total births), including 49 in London.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXIII

PROGNOSIS IN TRIGEMINAL TIC

CHRONIC paroxysmal neuralgia of the trigeminal nerve, or trigeminal tic, may be said never to be cured by drugs, or to disappear spontaneously. It may start gradually, with shoots like toothache, or it may leap suddenly into consciousness with a shattering explosion of pain in the face. Once started, the pain is bound to recur again and again, though there may be in some cases intervals of years of complete freedom in the earlier stages. Gradually the attacks become more frequent, and usually more severe as the years pass, till ultimately scarcely a day passes without numerous stabs of almost intolerable agony in jaw, tongue, nose, and sometimes eye and forehead.

I have seen two women who had suffered for over fifty years, one having commenced the paroxysms at the early age of twelve. Often, but not always, as time goes on the neuralgia may spread from the original site in one or other jaw, or possibly the eyebrow, until it involves all three divisions of the trigeminal area on one side. Sometimes the pain remains located in upper or lower jaw alone, but invariably if the pain starts in the first division, in eyebrow and forehead to top of head, the neuralgia ultimately spreads downwards to involve the nose and upper lip and cheek, spreading from the first into the second division, though several years may elapse before this takes place.

Inheritance of the disease is not very rare, the neuralgia almost invariably appearing at a younger age in the second generation, and again younger in the third. I have had two patients of a family in which nine members suffered, three in each of three generations, the disease appearing at the age of 16 in two sisters, and at 20 in their brother, in the third generation.

TREATMENT BY ALCOHOL INJECTION

The easiest form to treat successfully is third division tic, the pain affecting the lower jaw only and perhaps the same side of the tongue. A properly placed alcohol injection into the nerve at its exit from the foramen ovale will instantly numb the lower jaw, chin, and lip, and half the tongue, so that the tongue movements become free and easy, and no longer cause painful spasms, and eating and swallowing are immediately possible without causing any of the distress previously felt. Owing to the numbness of the left gum and inside of cheek and the half of the tongue, it is preferable for the patient to eat on the other side of the mouth; the weakness of the biting and chewing muscles on the affected side, produced by the involvement of the motor root in the alcohol injection, tends to upset what dentists call the "bite" and the alignment of the dentures. The motor fibres usually recover with 3 months, though the anaesthesia and freedom from pain may be measured by years. I have seen numerous cases of five years' standing and upwards with complete freedom after injection of the third division only, and I have seen recurrence after 13 years and 15 years, while another patient is still quite free after 26½ years.

The reason for the long periods of relief after third division injection, as compared with the results after second division injection, is that when the alcohol is injected into the nerve at the foramen ovale, a cer-

tain amount often enters the Gasserian ganglion and destroys a number of nerve-cells in its outer part, so that partial numbness and light anaesthesia is apt to be permanent, sufficient in certain individuals to keep the neuralgia at bay almost indefinitely. When the second division is injected, at or in front of the foramen rotundum, no alcohol will reach the Gasserian ganglion, and though complete and total anaesthesia of the cheek, jaw, and palate on that side may result, with immediate relief of the neuralgia, yet new nerve-fibres grow down from the ganglion cells fairly rapidly, and in twelve months or less sensation may be practically normal again, and thus no obstacle remains to the passage upwards of the painful impulses from the periphery.

ROOT RESECTION OR GANGLION INJECTION

Since recurrence of the neuralgia in second division cases is usual after a year or two, the question of either root resection or ganglion injection must be considered. If the second division alone is involved, then injection at the foramen rotundum should always be done as the preliminary treatment, for two reasons: first, because it is possible in a few cases to obtain relief lasting many years; and secondly, to accustom the patient to the permanent numbness that would result from the ganglion injection or root resection. A small proportion of patients object intensely to the numbness, and the preliminary injection will be a test as to whether they would prefer to endure the neuralgia, if it returns, or to put up with permanent numbness as the price of a cure. If the first division is involved together with the second, the pain shooting up the forehead to the vertex, and perhaps in the eyeball itself, then it will probably be useless to inject the second division only, and it will be necessary to deal with the ganglion at once, or else have the sensory root resected. It is possible in these cases to inject the inner two-thirds of the ganglion only, leaving normal sensation on the unaffected lower jaw and tongue, which is a considerable comfort to the patient. Though the motor root may be paralysed at first, it nearly always recovers within about three months. By the open method of operation for root resection, it is now possible to save the motor root in most cases, and from the method of fractional root resection, leaving uncut a small bundle of fibres on the inner side of the root, incomplete anaesthesia results, especially of the ophthalmic branch, so that the risk of keratitis is much diminished.

CARE OF THE CORNEA: KERATITIS

The care of the cornea is very important for the first few weeks after total root resection or ganglion injection. If, however, the eye is shaded from the first by a close-fitting curved straw-plait shade, no lint or wool being used under the shade, and the conjunctival sac washed out twice daily with weak (1 in 7) boracic lotion, then in almost all cases the eye remains healthy, and the shade can be gradually discarded after five or six weeks. If, through carelessness, or for other reasons, such as the presence of facial palsy, the cornea is insufficiently protected, or should there be a pre-existing conjunctivitis or trachoma, then keratitis is much more likely to supervene, and it will be necessary to close the lids by tarsorrhaphy, and not reopen them for several months. Hence, before deciding on a total root

resection or ganglion injection, it is important to examine the vision of the two eyes; if the eye on the side of the neuralgia is the only sound eye, the patient's difficulties are much increased by having the eye closed, even for a few weeks, and should serious keratitis develop, the loss of vision will be tragic. Fortunately, with proper care of the eye from the moment of completion of the injection, or operation, keratitis should never develop, unless facial palsy or conjunctivitis are present. Facial palsy is not a rare complication of root resection; it is associated with traction or other interference with the Vidian nerve as it runs beneath the ganglion.

OTHER COMPLICATIONS

With a ganglion injection, slowly and properly performed, facial palsy is very rarely seen, though occasionally vertigo, and nystagmus to the opposite side, owing to leakage of alcohol backwards to the internal auditory meatus, may give trouble for periods from a few minutes to an hour or two. Herpes on the upper lip and side of nose is common, both after injection of the ganglion and root resection, but it gives no real trouble and leaves no scars or post-herpetic pain. It is not a true zoster, and its serum reactions are those of herpes febrilis. Temporary diplopia is also met with occasionally, both after injection and root resection.

With total anaesthesia of the third division, there is a liability for the patient to bite the lower lip, inside of cheek, or even the tongue, during the first three days. This tendency is attributable to the strange feeling of the numb parts; but re-education is speedy, and no trouble of this kind occurs after the first few days, during which soft food only is advisable.

In a small proportion of cases, cure of the paroxysmal neuralgia, whether by injection or root

resection, may be followed by persistent burning sensations in cheek and eye; shooting pains may even be complained of, or a sensation of discomfort or coldness in the eye. Mostly these sensations appear to be of a psycho-neurotic nature. They do not appear at once, but a month or two after an operation which appears at first to have been the usual success. Possibly sympathetic nervous disturbance is a factor in some cases, and I have had one case in a young woman in whom stellate ganglionectomy relieved the symptoms.

BILATERAL TIC

In 4 to 5 per cent. of the cases similar neuralgic pains attack the other side; occasionally from the commencement both sides may suffer, though the pain on one side is usually much more severe at first; ultimately it is probably equally severe on the two sides, sometimes alternating. Women suffer from trigeminal tic much more frequently than men, perhaps twice as often, and when the disease is bilateral, the proportion of women to men is, as might be expected, doubled, about four to one.

Bilateral injection of the foramen ovale, if the two injections are performed within three months of each other, will cause jaw drop, and soft food will be necessary. Even though the anaesthesia remains total and permanent, the motor roots usually recover in a few months, as their trophic-cell nuclei are in the pons. If root resection is done, the motor root can usually be saved, but, if it is cut, it never regenerates. Bilateral facial anaesthesia does not worry the patients much, though the processes of eating may require practice with a mirror.

WILFRED HARRIS, M.D., F.R.C.P.

Senior Physician, Hospital for Epilepsy and Paralysis, Maida Vale; Consulting Physician, St. Mary's Hospital, London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Lt.-Comdr. T. L. Cleave to *President* for course.

Surg. Lts. J. M. Fitzpatrick to *Enterprise*; N. C. Hepburn, W. F. Viret, and F. H. Lamb to *Pembroke* for R.N.B.; H. G. Silvester and D. Simpson to *Victory* for R.N.B.; A. E. Ginn, D. Shute, and J. Lees to *Drake* for R.N.B.; and J. Carlton to *Hood*.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. P. C. Lewis to R.M. Barracks, Plymouth.
W. S. Walton entered as Proby. Surg. Lt.

ARMY MEDICAL SERVICES

Col. J. P. Helliwell, C.B.E., late A.D. Corps, to be Maj.-Gen.

Lt.-Col. J. V. M. Byrne, from A. D. Corps, to be Col.

Maj.-Gen. J. P. Helliwell, C.B.E., from Asst. Dir.-Gen. Army Med. Servs. (for the Dental Serv.), to be Dir. Army. Dental Serv.

ROYAL ARMY MEDICAL CORPS

ARMY DENTAL CORPS

The undermentioned Majs. to be Lt.-Cols. :—
A. B. Austin, F. H. W. Beer, J. P. Duguid, A. Gibson, and R. J. Condie.

The undermentioned Capts. to be Majs. :—
W. Wormington, J. B. Cowie, M.M., F. H. R. Davey, F. F. Anslow, W. J. R. E. Edwards, F. S. S. Whiter, D. C. Blyth, F. G. Arnold, R. H. N. Osmond, W. G. Bradbeer, and B. J. Swyer.

The undermentioned Lts. to be Capts. :—
H. C. Dobbie, G. M. Sinclair, H. W. South, C. E. Howell, K. H. Coulton, J. E. C. Robinson, and R. H. Green.

ROYAL AIR FORCE

The undermentioned promotions are made with effect from Jan. 1st, 1936 :—

Air Commodore to be Air Vice-Marshal : Alfred William Iredell, K.H.P.

Wing Commanders to be Group Captains : Gerald Struan Marshall, O.B.E., and Raymond William Ryan.

Squadron Leaders to be Wing Commanders : James Henry Hope Maxwell, William Edward Barnes, James Daly Leahy, M.C., Edward Cyril Knowles Henry Foreman, and William John Greaves Walker.

Flight Lieutenant Leonard Freeman is promoted to the rank of Squadron Leader.

Dental Branch.—Flying Officer William Vernon Anthony Denney, L.D.S., is promoted to the rank of Flight Lieutenant.

The undermentioned are granted short service commissions as Flying Officers for three years on the active list :—

C. F. R. Briggs, H. D. Conway, L. M. Crooks, W. J. Fowler, I. K. Mackenzie, H. C. de B. Milne, D. J. Sheehan, and R. F. Wynroe.

Dental Branch.—R. M. Brown and W. E. Nelson are granted non-permanent commissions as Flying Officers for three years on the active list.

INDIAN MEDICAL SERVICE

Lt.-Cols. P. S. Mills and D. C. V. Fitzgerald, M.C., to be Cols.

The King has approved the award of the Distinguished Service Order for gallant and distinguished service in action in connexion with the recent Mohmand operations, North West Frontier of India 1935, to Capt. F. J. Doherty, M.B., I.M.S., attached 5th Battalion (Queen Victoria's Own Corps of Guides), 12th Frontier Force Regiment, Indian Army.

SPECIAL ARTICLES

MEDICAL EDUCATION AND MEDICAL RESEARCH*

By W. W. C. TOPLEY, M.D. Camb., F.R.C.P. Lond.,
F.R.S.

PROFESSOR OF BACTERIOLOGY AND IMMUNOLOGY IN THE
UNIVERSITY OF LONDON AT THE LONDON SCHOOL OF
HYGIENE AND TROPICAL MEDICINE

We should all, I fancy, be hard put to it, if asked to explain what medical research means. For our present purpose we may take it as a convenient label covering a multitude of interrelated activities, all concerned, immediately or remotely, and sometimes very remotely, with the study of disease in man. Proceeding from this *ad hoc* definition, we may consider how our present medical curriculum fits people to work in different parts of this very extensive field.

Before doing so I should like to make two things clear. Firstly I am, in the main, thinking in terms of the whole-time research worker—the man who intends to devote himself to research, or to research and teaching, as opposed to practice. Secondly, I am airing personal opinions with which I have no reason to suppose that anyone would agree.

Words are tricky things, and I may easily fail to convey the meaning I intend, or to put the emphasis in the right place; so that I propose to start at the end, and state my conclusions quite clearly before I give my reasons for them. The theses that I am attempting to maintain are these:

(1) That the present medical curriculum, in its usual form and including all such modifications of it as are in sight, however adequate it may be for the purposes for which it was designed, fails badly as a method of providing recruits for medical research, except, perhaps, in the strictly clinical field.

(2) That the reason why the medical curriculum fails, from the research point of view, is that, except in the strictly clinical field, the success of a research worker will depend more on his knowledge of the basic sciences on which medicine is founded than on his detailed knowledge of practical medicine or surgery in the clinical sense.

(3) That medical research, at least on its laboratory side, is not an activity that can profitably be adopted as an alternative to practice at some late stage of a student's career, but must be consciously prepared for, from his earlier university days onward.

The Background Needed for Research in Various Fields

In giving my reasons for these statements, it will be convenient to start by taking samples of different kinds of research workers, and considering the things they must know in order that they may work effectively.

CLINICAL RESEARCH

To preserve a proper sequence I am forced to start with a subject on which I can speak with no authority at all—medical research in what is, perhaps, its strictest sense, the acquirement of new knowledge in regard to disease by observations carried out at the bedside. The proper name for this is clearly clinical research. Speaking as an outsider, it has always seemed to me that clinical research, in the true sense

of that term, demands a combination of qualities, and a breadth of knowledge, of a very exceptional kind. It may, I think, be laid down as an axiom that no one is likely to make any real advance in our knowledge of disease unless he has the scientific outlook—science and pseudo-science are poles apart. Pseudo-science is even harder to define than medical research; but since it is a very horrid and insidious intellectual infection, to which we medicos are freely and frequently exposed, it may be worth noting some of its signs and symptoms. One of the worst is the uncritical application to practical medicine of procedures derived from physiological or pathological principles under conditions where there is no evidence that those particular principles are applicable. I suppose that the exploitation of hormones, or of bacterial vaccines, can supply some of the most fearsome examples, just as, when used as they should be, these reagents afford some of the most striking instances of the scientific cure or prevention of disease. Another symptom of medical pseudo-science is a confusion of apparatus with method, a belief, for instance, that things done in a laboratory are necessarily more scientific than things done outside it. In the absence of a clear grasp by a clinical worker of the implications of laboratory tests, or of a close and personal liaison between workers in the laboratory and in the ward, this form of the disease can be very harmful. Perhaps the most insidious form in which pseudo-science can attack us is that of rationalisation—the tendency we all have to make up reasons as to why we do things, or why things happen, without submitting our reasoning to the tests of repeated observation and experiment that science dictates. If we give way to this, if we mistake a guess for a working hypothesis, and a working hypothesis for a well-established theory, then we are lost.

But the scientific outlook—the determination not to go beyond our evidence and to test each link in our chain of reasoning—is much easier to maintain when the things we are thinking about do not matter very much to ourselves or anybody else. The more they matter, in this emotional sense, the harder it is to regard them as data for consideration, or problems for investigation, rather than as practical problems that have to be tackled somehow or other, and as quickly as possible. Now clinical medicine does matter very much, and I should say that the purely scientific outlook is, for the ordinary person, entirely impossible. If it were possible it would, I think, defeat itself; because the subject of clinical research is not sickness, but the sick person, and a lack of emotional understanding will render the clinician blind to half his problem. So we must make many demands of our clinical research worker. He must be able to separate from the mass of data with which his experience presents him those that can be dealt with on strictly scientific lines. These will, of course, often include the emotional reactions of the patient; but the clinician, in his capacity of investigator, must try to regard them as though they were figures in a sum, or the results of titrations, or steps in an argument. But also, and at the same time, he must do the best he can for his patient, and this means that he must often use measures which, as a scientist, he would regard as based on a very doubtful foundation of ascertained fact. The thing can be done. It has been done, and done supremely well by some of the great clinicians. It is of the utmost importance

* Based on an address delivered to the Cambridge University Medical Society on Oct. 23rd, 1935.

to medical science that it should continue to be done well in the future. But it demands a clarity and adaptability of mind of a very high order. I think, also, though here I speak with the greatest diffidence, that this field of work in the future is going to make even greater demands than it did in the past, when so much of the purely clinical territory remained unmapped. I should guess that it will not be easy for the clinical investigator of the future to go very far unless he is a master of some special technique which, in its essence, is non-clinical, though it is applicable to clinical problems. Or, perhaps, it would be truer to say that the man who relies on clinical methods alone—clinical in the restricted sense—will find his field of activity greatly restricted, while the man who has mastered some ancillary technique, chemical, or physiological, or pathological as the case may be, in addition to his clinical training, will find problems in plenty waiting for solution. I do not, of course, mean that he must be a chemist, or a physiologist, in the broad sense, as well as a clinician—that, I suspect, would be an impossibility. But, if he is to work in any of those borderlands that call so urgently for exploration, he should be expert in that limited non-clinical field which he hopes to apply in his clinical studies. Of one thing I feel very sure, clinical research in the true sense will never consist in engaging other people to make a host of tests and examinations, using techniques which one has not mastered oneself, and then trying to add the results together. It is, of course, obvious that there are medical problems that demand for their solution the application of methods drawn from several different branches of science. But the proper method of approach to such problems is the method of team-work—a question that I hope to discuss later. Those who desire a more detailed and authoritative account of clinical research than I can offer should refer to the Iluxley lecture given by Sir Thomas Lewis.¹

LABORATORY WORK IN HOSPITALS

Having ventured over a frontier which, perhaps, I should never have transgressed, I can turn to what is, to me, more familiar ground. The laboratory worker, to use a useful generic label for the multitude of scientific activities that are ancillary to medicine, has fewer demands made upon him than has the research worker in the wards. He is not, in general, responsible for the care, or treatment, of the sick person, and this makes it much easier for him to view his facts dispassionately, and to treat them as data which gain significance only in so far as they add together to form an ordered whole on which at least a tentative conclusion can justifiably be based. But it is clear that the term "laboratory worker" is almost as vague and elastic as "medical research." There are those who work in the laboratories attached to our great teaching hospitals, and even among these there are significant divisions. Of clinical diagnostic pathology I do not wish to say much. A great part of it, in my personal view, belongs to the domain of clinical medicine rather than pathology; for I do not see why the clinician's technical armoury should be limited to the instruments and methods that past generations happened to employ. The clinical pathologist must clearly be at least a competent clinician as well as a laboratory worker—competent in the sense of having an intimate knowledge of disease as it occurs in man, and an ability to weigh clinical evidence, though not

necessarily the ability to obtain that evidence for himself.

When we view pathology—including under that term bacteriology and chemical pathology—from the angle of the hospital medical school rather than from that of the ward, the connexion with the sick person, as such, becomes more remote. We are now hardly concerned at all with the fate of Mr. A. or Mrs. B., not at all, in our professional capacity, with their happiness or well-being apart from the particular disease from which they are suffering. Indeed, we never meet them as human beings. In so far as our humanitarian aims and aspirations are concerned we shall not be attempting to cure them of cancer, or tuberculosis, or any other malady, but we shall hope that, through our own efforts and those of the workers who follow us, the time will come when no Mr. A. or Mrs. B. need die of these particular diseases. We shall realise, moreover, that the more we can put the present Mr. A. and Mrs. B. out of our minds, and concentrate on the disease as apart from the individual, the more likely we are to contribute something at least to the solution of our more general problem. Inasmuch, however, as we are still largely concerned with disease in man, we shall need some clinical background, though not so much as the clinical pathologist requires. But, if our requirements decrease in terms of clinical experience, they increase in terms of the basic sciences. More and more is it becoming necessary for the research worker in pathology or bacteriology to possess a sound working knowledge of organic and physical chemistry. Without it, his activities will be very seriously limited.

ACADEMIC MEDICAL WORK

And now we pass to those laboratory workers whose spheres of activity lie in universities or research institutes, instead of in hospitals. They form a continuous series that defies arbitrary division or classification. They range from university departments of pathology, through the departments of physiology, of psychology, of pharmacology, of biochemistry, of biology, of chemistry, of physics, of mathematical statistics, and so on, their immediate relation to disease growing more and more remote, and the number of their workers who are in any way concerned with medical problems growing proportionately fewer and fewer. But remoteness from the centre does not necessarily denote inactivity or unimportance. Sometimes it coincides with a locus of particularly active growth. It does not seem to me unlikely that many of the major advances in medicine will come in the future from branches of science that have no immediate connexion with the prevention or cure of disease. It is a fairly safe guess, because that is the way in which all applied sciences have advanced; and medicine has at least one example it can never forget—the work and life of Louis Pasteur.

It should, I think, be emphasised that there is a significant change in the method of approach as we pass from clinical medicine, through pathology, physiology, and biochemistry to the remoter ancillary sciences—ancillary so far as medicine is concerned. The clinician's problems are inexorably posed for him. He has considerable freedom of selection among them, but he cannot often adapt his problem to his technique, he must try to develop his technique to cope with his problem, and even when this technique is very imperfect he must do the best he can with it. The pathologist again has many of his

¹THE LANCET, 1935, I., 723.

problems set for him, but his choice among them is freer. There is less urgency in his work. He can neglect altogether those problems that seem to him to offer no hope of solution. He can make free use of animal experiment—indeed, pathology is following physiology in becoming more and more an experimental science—and he can isolate his data and phenomena far more than the clinician can, concentrating, if he chooses, on the study of one particular factor among the many that are involved in any of the manifestations of disease.

When we pass from pathology to physiology—if, in truth, we do pass any frontier beyond a convenient difference in academic labelling—we meet with a further decrease in the part played by the observation of phenomena as nature presents them to us, and a corresponding increase in the part played by controlled experiment. With this change there comes an added freedom to select problems in relation to available knowledge and technique. I need not enlarge on the enormous advantage of the introduction of new technical methods into physiology, or on the advances that have followed the adaptation of chemical or physical methods in the solution of physiological problems. The point to note is that the physiologist, when considering any problem, is free to think mainly in terms of technique. If he can devise a method of attack that offers reasonable hope of yielding a significant answer, he will be tempted to proceed. If he cannot, he will probably select some other problem, rather than work with unsatisfactory tools. I suppose that my physiological colleagues would agree with me that Claude Bernard's words remain as true to-day as they were when written 70 years ago:—

“The prudent and reasonable course at the present moment is to explain all that part of disease which can be explained by physiology, and to leave that part which we cannot so explain to be explained by the future progress of biological science.”

Claude Bernard, it may be noted, steadfastly refused to recognise any division between physiology and pathology, beyond that incidental to an arbitrary system of labelling, and I think I may best express his outlook on the relation of experimental science to clinical medicine by a further quotation, which occurs in the same passage of the same book.

“But if, instead of this, some delusive approach of physiology gives rise to the ambition to explain prematurely at one step the whole of the disease, then one loses sight of the patient, one gets a wrong idea of the disease, and, by a false application of physiology, experimental medicine is hindered instead of being assisted in its progress.”

That, also, is as true to-day as it ever was.

Is it necessary for the physiologist, or the experimental pathologist, to have any detailed acquaintance with practical clinical medicine? For the moment I would merely note that the necessity is clearly much less than in the case of the clinical pathologist or the morbid anatomist. When we come to the biochemist, the experimental biologist, the chemist without the bio-, and the physicist, we are on rather different ground. In none of these instances is there any reason beyond inclination for the research worker to concern himself with medical problems in any shape or form. If he does so, it will be, or should be, because the knowledge and technique at his disposal are of a kind that are ripe for application to some problem of scientific medicine in its broadest sense. One implication is, I think, obvious. In all these fields the value of a man's contributions to medical research will depend mainly on his ability

as a chemist or a physicist. How much medicine must he know, or how much biology? It will be more convenient to consider that question a little later.

I have not, I am sure, exhausted the field of medical research in these brief glances at different parts of it. I have not, for instance, discussed the important subject of psychology, nor the study of the diseases of herds that is the domain of the epidemiologist. But it will, I think, be apparent that the territory covered is of very wide extent; and we should, I take it, all agree that any wise policy that takes the long view must aim at keeping the whole of it healthy, and active, and coördinated.

The Modern Team

This brings us naturally to the question of team-work; and successful team-work is, I believe, the only method that will enable us to advance rapidly and surely. The range of knowledge required for the solution of most of the problems that face us is, I think, beyond the command of any one man, or of any group of men trained in the same technique. The teams will vary in their character and composition according to the particular field in which they are working. At one end of the scale the clinically trained members of the team will be the dominant partners, doing most of the work and seeking help from their non-clinical colleagues. At the other end of the scale there will be teams with no clinically trained members at all. In between there will be every kind of gradation according to the knowledge and technique that each problem demands.

I do not want to give an impression that, in regard to this question of team-work, I am merely painting a picture of what may be in years to come. I am giving a picture of things as they are to-day. In seeking illustrations it is easier for me to take them from the ground I know best—the middle ground where pathology and the basic sciences are both involved, but clinical medicine does not come prominently into the picture.

The two great institutes of medical research in this country—research as apart from teaching—are the National Institute for Medical Research at Hampstead, and the Lister Institute of Preventive Medicine at Chelsea. If you look at the reports of these institutes for last year, 1934, and glance through the degrees and qualifications of the scientific staff and workers, you will note the following figures.

At the National Institute for Medical Research there were 36 workers: of these 13 had a medical degree or diploma, 3 had a veterinary diploma, and 20 had a science degree but no medical qualification.

At the Lister Institute there were 27 workers: of these, 11 had a medical degree, while 16 had not.

Taking them together there were 24 medicals as compared with 39 non-medicals.

The non-medical workers were, in fact, about half as many again as those with a medical qualification. And it should be noted that the non-medicals—mainly chemists and biochemists, with some biologists and a few physicists—were not in any subordinate position, assisting those who happened to be medically qualified with the problems on which the latter were engaged. They included, and include, heads of divisions and departments; and they number among them some of the most distinguished scientific workers in our common field. That is the sort of world into which those of you who decide to devote yourselves to medical research on its non-clinical side, are going; though in university

departments, where the teaching of medical students is combined with research, you will still find a considerable predominance of medically qualified workers.

I have extolled the virtues of team-work; and I have given you my reasons for believing that, for most of us, there is no alternative. But no human system is all virtue and no vice, and teams have their dangers as well as their advantages. The teams I believe in myself are loose, elastic things, easily and naturally modified as need arises, not rigid and ordered, with a set hierarchy of workers. Most members of a team should, I think, be tackling particular problems of their own, as well as those on which the team is engaged, though there may well be a call for whole-time work over a relatively limited period. In any case, I am very sure of one thing, that successful team-work depends on mutual understanding; and mutual understanding, like most things worth having, demands some effort. In this case the understanding that is most required is an understanding of other peoples' technique, including in that term the way their minds work as well as the methods they employ. I do not mean, of course, a knowledge of their methods that would enable one to do their work oneself, but a sufficient acquaintance with the technical processes they employ, and the kind of things they do with them, to enable one to see a problem, if only dimly, through their eyes. To this kindergarten kind of knowledge over the general field there should, I think, be added a deeper knowledge of some limited part of it that lies adjacent to one's own special sphere of activity. We must, I fear, be specialists, but the more overlapping we can manage the better for us all.

A relatively detailed knowledge of some subject ancillary to one's own can be obtained only as a part of a planned educational syllabus; but the more general knowledge can most easily and pleasantly be grafted on a rudimentary training in the basic sciences by personal contacts and informal talk and discussion. These arise naturally among the workers in any research institute, or university department; but they come more easily, and tend to be much more fruitful, if the habit is acquired early in life. You will be missing a great part of what a university has to give if you do not take every available opportunity of discussing scientific problems with your non-medical fellows, whether, at the start, you know anything about those problems or not.

What Kind of Curriculum

And now we may turn to the strictly educational side of our subject, and inquire what kind of curriculum is needed to fit a man to work in the wide and varied field that we have been describing.

THE TIME LIMITS OF CAPACITY FOR LEARNING

Here, again, I must start my argument by raising a question that I am ill-equipped to answer. I gather, from the reports of this year's meeting of the British Association at Norwich, that the capacity for learning does not cease as soon as we had supposed, and that even for the fifty-or-thereabouts there is some hope left. But I gather also that the tests applied were largely memory tests, and the learning of languages. So far as scientific knowledge is concerned, I am inclined to think that, for most of us at least, there is little hope of acquiring facility in a new branch of science after the later twenties. I do not mean that one could not do it if it were possible to drop all other work and devote oneself wholly, for several consecutive years, to learning

the new technique, and the facts and arguments derived from it. My feeling is that real knowledge of a science is so much the result of an integration of thought and action that the subject has to be lived with for several years at least before the necessary background can be attained and the new habits of thought acquired. I doubt, for instance, whether any ordinary man can gain a working knowledge of chemistry, or physics, in his spare time, after he has completed his formal education. I know, at least, that my own attempts to gain such knowledge have been ignominious failures.

If I am right in this, and if we accept the not-illiberal view that the average man cannot devote more than six years or so to his whole-time education, counting from the commencement of his university career, then we have those six years to allocate and no more. The research worker will, of course, go on learning all his life, indeed, his learning in this sense will hardly have commenced by the time that his six years are over; but he will be building on foundations that have been fixed during his student years, and he will not usually be able to acquire new, or different, ones.

It is, then, quite useless to plan our curriculum for the medical research worker as though his mind were a limitless receptacle, into which one could pour a large volume of a standard mixture of educational ingredients, leaving room for the addition of more detailed and specialised knowledge of the basic sciences, as and when required. By the time his six years are over he will be an embryo clinician, or physiologist, or chemist, or physicist, or so on. He will be one of these things, not all of them. He may, it is true, have developed along a line that winds across one of these arbitrary frontiers; but if, for instance, he has grafted a general knowledge of physiology on to a basic foundation of chemistry, the lines of his future development will be no less clearly marked.

The Merits and Demerits of Vocational Medical Training

Now it is surely clear that the medical curriculum, as we know it to-day, cannot possibly cope with the educational problem that presents itself. It was never meant to. It was designed, and rightly designed, as a vocational training for men and women who desire to practise medicine, to undertake certain duties to the individual and to the State, and to enjoy the privileges conferred by a registrable qualification. To obtain this qualification, by all but a very few of the available avenues, takes practically the whole of the six years that we have allowed for whole-time study. Let us take the thing as it stands, and see how it meets, or fails to meet, the requirements of the different classes of research workers that we have referred to.

FOR THE CLINICAL INVESTIGATOR

As regards the clinical investigator I have little to say, because I do not know. I should guess, as I have said, that he will gain very greatly by having carried some preclinical scientific subject well beyond the stage prescribed by the ordinary medical curriculum. He will gain in two ways. He will have acquired a knowledge and technique that he can develop and apply in later years, and, what is probably more important, he will have studied some subject sufficiently deeply to have approached the critical stage, and to have gained some insight into scientific method. He will thus attack his clinical

studies with a certain ingrained scepticism, a habit, more or less developed, of sifting evidence, that will enable him to make better use of his years in the wards.

Is this all that is required? I should not venture on an answer; but I may quote from the address by Sir Thomas Lewis to which I have already referred. He says:

"... there is room for a university degree in medical science, which should not include medicine, surgery, or other branch of medical practice as such, but should centre upon disease, as this is studied in human beings; and this degree should be intended to mark those contemplating an academic career."

He is speaking here of a degree in scientific clinical medicine grafted on a modified curriculum that has led to a registrable qualification; and, clearly, a licence to practise is essential for the man who wants to become a clinical investigator. I would ask you, however, to remember his suggestion, which seems to me an eminently wise one, in view of a possible extension of it which I propose to discuss later.

FOR THE PATHOLOGIST AND BACTERIOLOGIST

In regard to the pathologist or the bacteriologist, it is, as I have already said, my firm conviction that he will be at a serious disadvantage if he has not obtained a firm grip on some experimental science before he studies clinical medicine. I suffer from that disadvantage myself and I know what it means. It may be urged that a man does not, in fact, make up his mind that he wants to become a pathologist until he has completed, or almost completed, his medical education. But I fear that in the majority of cases he will then have made up his mind too late, unless he is prepared to spend a year or two learning what he could have learned more easily at an earlier stage in his career. Is it essential that every pathologist in the future should hold a medical qualification? Is it really necessary that he should devote three years out of his precious six to attaining those multitudinous items of knowledge and technique that the General Medical Council and the various licensing bodies demand from those who are going to treat sick men and women? At present there is no escape; and it will, I should guess, always be wise for those who propose to study pathology in close contact with the ward to go through the same educational mill as their clinical colleagues. For the rest of us, whose work lies wholly or almost wholly in the laboratory, I am not so sure. It is true that one tends to undervalue what one has and to yearn for the unobtainable, but I know that I personally would gladly sacrifice much that I remember vaguely from my hospital days for a working knowledge of chemistry.

I believe that the best solution would probably be for some academic pathologists to take a full medical curriculum, while others followed the routes that I am going to suggest as possible alternatives. The research worker is seldom isolated—it is never healthy that he should be—and among groups working in research institutes or university departments it would be all to the good that, even among those who are all labelled pathologists, different workers should have a rather different background. But there must be no differentiation in regard to status or opportunity. By whatever road a man travels all posts, including the highest, must be open to him. At the present time the man who enters the pathological or bacteriological field, even on its academic side, without a medical qualification will

find many posts closed to him; and this is a risk that few can afford to take.

FOR THE PHYSIOLOGIST AND BIOCHEMIST

As for the physiologist, those whom I have known were marked as physiologists before they approached a hospital ward, and were quite deliberately taking a medical degree as a preliminary to returning to the work of their choice. We know from example that three years in the wards, with a medical qualification at the end of it, is not an essential preliminary to the highest achievement in the physiological field. Is it, on the average, an advantage? I cannot tell. But I am sure that such advantage as there is could be purchased much more cheaply; and an educational waste in one's active learning years is not to be regarded lightly.

The biochemist, in so far as he is concerned with medical problems, I should class with the physiologist, and here again I would note that some of those whose work has contributed most notably to medical science possess no medical degree.

FOR THE CHEMIST AND PHYSICIST

And the others, the chemists without the bio-, the physicists and so on. No one would seriously suggest that they should be forced to take a medical qualification. Their training in their own subjects will take them four years or more before they reach a standard that will enable them to make use of their knowledge in the field of medical research. How are we to provide for them? For many, of course, no provision is required. They will pursue their own careers, lending occasional assistance in our problems when these have reached a stage at which they have become purely chemical, or physical, as the case may be. Medical science can never make provision within its own borders for all its needs. We shall always be asking for help from our senior colleagues in related branches of science. But it is quite clearly desirable that some of those who have mastered the technique and conceptions of one or other of the basic sciences should definitely enter the medical field and make a career for themselves within it. The men we want will not, and I do not think they should, enter this field in any position of permanent dependence on their medical colleagues; but if they have no knowledge of physiology and pathology they can hardly escape that position. Moreover, I do not myself believe that, without that knowledge, they will be in a position to grasp the fundamentals of the problems which their basic training would enable them to attack.

A Short Training in Medicine for the Scientist

Is it altogether premature and absurd to suggest that there is a real need of a training in medicine that will not lead to a licence to practise, nor to a position as a clinical investigator, but will give a student who is already equipped with a sound foundation in one or other of the basic sciences on which medicine is built sufficient knowledge of disease as it occurs in man to enable him to turn his special knowledge to account in the medical field? The training in the wards would, of course, have to be preceded by an adequate training in anatomy, physiology, and pathology—adequate that is for this particular purpose. But is it really sensible to deny to those whose help we badly need any insight into clinical problems, except on the condition that they work through a long and overcrowded curriculum,

and jump a number of examinational fences that were designed for a quite different purpose ?

The Ordinary Medical Student

I have in this address said nothing of the man whose future lies in general or consulting practice, or in the administrative field of public health. He falls, I think, into another category. The choice has to be made. You can be a research worker or you can be a practitioner. I do not believe that you can be both. Medical science, if you wish to serve her, demands all your time and energies ; so does medical practice. The choice will depend, if you are wise, mainly on your mental reactions, so far as you yourself can judge them. If you let other considerations weigh with you, you will risk all the discomforts of a square peg in a round hole. There are of course no hard-and-fast categories. Some men can be happy and successful either way ; but some, I think, cannot. There are minds that have a natural liking for searching out unsolved problems and following them through to a finish, or as near to a finish as they can. The problems must be sought or selected, not forcibly presented ; and the time and energy required for their solution must not be too greatly encroached on by a host of unrelated activities. Such minds will be profoundly unhappy if placed in an environment in which this unhurried continuous pursuit of some chosen problem is impossible. Medical practice is no place for them. There are other minds that work best under the stimulus provided by some insistent practical need, and that have the capacity of facing a multitude of problems at one and the same time, and enjoying the rush and turmoil of it all. Such minds often suffer boredom if forced to concentrate for long on a question that has no obvious practical issue. Given the requisite skill and sympathy, they will do well in practice ; but in the research laboratory they may find themselves on foreign soil. There is no better or worse in it, no higher or lower. It is a question of temperament. No one with any sense of values would attempt to balance the care of the sick against the discovery of new facts about disease. Both are things worth doing, and both need doing well, and with one's whole mind.

I do not mean, of course, that no advance in medical knowledge comes from practising physicians or surgeons ; that would be merely absurd. Their contributions have been many and important ; but any investigations that they undertake are incidental to their main work, and are therefore determined and limited by it. They have neither the time nor the opportunity to tackle problems of the type we have been considering.

The practitioner's daily work, however, presents him with endless opportunities for observation and for the accumulation of data that can be obtained by no one else. If his observations are properly made, and properly recorded, they may well be of great value, to others as well as to himself. There is, I think, a dangerous fallacy hidden in the conventional division between medical science and medical art. They may be regarded as antitheses. This is entirely false. Some part of medicine is "scientific," in the sense that we are able to apply clear and definite physiological or pathological knowledge in the diagnosis, prevention, or cure of disease. This field is rapidly enlarging, and each enlargement means a corresponding increase in the efficiency of our work. A large part of medicine would, at the moment, fall into the category of "art," in the sense

that we have as yet no "scientific" knowledge to apply. But the man who neglected his art whenever scientific knowledge was available would be a very poor practitioner, and the man who does the best he can when facing a practical problem in the light of half-knowledge, or with no "scientific" knowledge at all, relying on his own experience and his own observations so far as they will take him, is a perfectly good scientist. The thing that matters is that he should realise clearly what he is doing. He must use science, when science can help him ; and to use it he must have a working knowledge of it. Above all, he must avoid pseudo-science like the plague ; and that is not always easy. The scientific outlook, in this, which is its true sense, is just as important in practice as in research.

The Curriculum Leading to Medical Practice

I emphasised at the beginning of this address that I was discussing the medical curriculum as it affects the future research worker. In closing, I should like to make it equally clear that I am not suggesting that this is the angle from which the problem of future changes in that curriculum should be approached. It would be absurd, in considering any possible reforms, to allow the interests of that small band of men and women who intend to devote themselves to the academic side of medicine to weigh against the interests of the great mass of students whose future lies in practice, or in the administrative field of public health. All that I have done is to stress the importance, to the future research worker, of making full use of the preclinical years, and to suggest a possible avenue by which we might bring into the medical field research workers in other branches of science, whose entry as full partners is rendered difficult or impossible by our present system. If I were tempted to offer any suggestion as to the reform of the medical curriculum as a whole it would be that it needs a greater elasticity and some degree, at least, of differentiation. Apart altogether from the special needs of medical research, I do not myself see how a single rigid curriculum can possibly provide for the training of all those practitioners, specialists, semi-specialists, and medical administrators on whose activities the prevention and treatment of disease depends. There is, of course, a rapidly growing system of post-graduate diplomas and degrees that serve to train men and women for specialised medical activities, and these will certainly become more and more important in the future ; but there must be some limit to the total curriculum. If something could be done to lighten the general burden, to reduce the number of facts and the range of technical knowledge that have to be mastered by every medical student, so that he had a little time in which to think, it would, I believe, be a very great advantage to the profession as a whole. I have already referred to the suggestion of Sir Thomas Lewis that a modified and shortened medical curriculum might be followed, for those who wish to become clinical investigators, by a special course in scientific medicine. Could not this process of simplification and elimination during the earlier clinical years, with differentiation during the last year or so, be considerably extended, to the advantage of all concerned ? But such questions as these lead inevitably to a consideration not only of medical education but of the whole organisation of medical practice, and I have neither the time nor the courage—perhaps I should say the bravado—to enter on so thorny a field of debate.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

MATERNAL MORTALITY IN SCOTLAND

IN spite of the fact that some six months have elapsed since the publication of the report by two medical officers of the Department of Health for Scotland as the outcome of an inquiry into maternal mortality and morbidity in Scotland resentment is still being expressed by general practitioners here at what they regard as criticism of their midwifery. It will be remembered¹ that the report analysed the circumstances attending the deaths of 2527 mothers in childbirth, and estimated that 58·7 per cent. of these could have been avoided; 37·1 per cent. were attributed to some faulty technique of the attendant, including doctor, midwife, and institution in this category, and 21·6 per cent. to the failure of the patients to obtain advice or to follow the advice given. A circular is now being issued to all county and town councils in which the Secretary of State for Scotland urges them to consider in what directions the maternity services of their area may be improved. As a first step he suggests that a survey of the local maternity services should be completed by Feb. 29th, 1936. The circular also recommends local authorities to take immediate effective action on certain of the recommendations contained in the report, particularly as regards the provision of antenatal services, and to consider whether and on what conditions the services of obstetricians would be made available to general practitioners for consultative purposes.

VOLUNTARY HOSPITALS

At a meeting shortly before Christmas, Sir John A. Roxburgh, chairman of the Western Infirmary, Glasgow, described the voluntary hospital system as "a priceless possession." It would be a calamity, he held, if the voluntary principle could not be maintained and developed. Much could be done to maintain it by coöperation with the public health authorities. The chairman of the Royal Hospital for Sick Children, Glasgow, said that voluntary hospitals were entitled to State recognition and State protection so long and in so far as they continued to function efficiently. The voluntary hospitals recognised that they could not provide all the hospital services required, and were prepared to coöperate cordially with the rate-aided hospitals. Recent demonstrations of the confidence felt by Scottish people in this system are not lacking. The trustees of the estate of the late Mr. George Cuthbertson, shipowner, Glasgow, have announced that a sum of £116,000 will be allocated to various hospitals, churches, and other charitable bodies in Glasgow. The Glasgow Royal Infirmary and Glasgow Western Infirmary receive respectively £10,000 and £9,000.

A Government commission is now sitting in Edinburgh to consider the whole subject of the health services of Scotland.

DISPENSARY SERVICES IN GLASGOW

The remarkable increase in the popularity of the dispensary services of Glasgow during this century is the more striking when we realise that this period has seen many additions to the avenues through which medical advice may be sought. Dr. A. K. Chalmers, in an interesting analysis contributed to the *Glasgow Herald*, attributes the flock of attendances at the

dispensaries partly to the present drift towards the institutional treatment of disease, and partly to the gradual reduction in the numbers of the fee-paying classes. The figures of attendances at 13 of the principal dispensaries indicate that over 300,000 "first attendances" and "new cases," and over a million attendances were made during 1934. The attendances in the year 1901 were less than a third, and in the year 1911 little more than half those in 1934. Dr. Chalmers estimates that a population of about 1,704,000 is now served by the dispensary services in Glasgow. There is unfortunately a lack of coöperation between the dispensary physician and surgeon and the family doctor—a large proportion of the dispensary clientele coming to the dispensaries without any medical reference, and Dr. Chalmers fears that this tendency will impair the efficiency of both private and consulting practice.

PHYSICAL EDUCATION IN SCHOOLS

At the annual congress of the Educational Institute of Scotland, recently held in Glasgow, Dr. J. Jardine read a paper on physical education. Referring to intelligence tests, he said that while these had been of great service in educational classification, they provided only rough estimates of a child's natural capacity. No tests at present devised could differentiate temperamental manifestations or suggest a reason why one child was unstable and another stable. Dr. Jardine held strongly that the biological needs of the child should receive first consideration. He deplored what he described as the atmosphere of tension in the primary schools; large classes resulted in strain upon the teacher, and, through him or her, upon the children. Any system of education which demanded that the whole school day and all the evening should be given over to set tasks of an intellectual character was to deprive the child of its biological rights.

(FROM OUR OWN CORRESPONDENT)

A NATIONAL HEALTH INSURANCE BILL

ON Dec. 18th, 1935, Mr. Sean T. O'Kelly, Minister for Local Government and Public Health, introduced a Bill to amend the National Health Insurance Acts and also the Widows' and Orphans' Pensions Act. The text of the Bill has since been made public. As concerns National Health Insurance two important changes are proposed. One has to do with the method of electing a committee of management, and the other is the bringing of soldiers of the permanent force and members of the reserve force into the scope of National Health Insurance as if they were in the sole employment of the Minister for Defence. At present the Unified National Health Insurance Society, which includes all the previous approved societies, is governed by a provisional committee of three persons appointed by the Minister. This provisional committee was to exist for three years from the coming into force of the National Health Insurance Act of 1933, and was then to be replaced by an executive committee of fifteen to be elected by the insured persons. The effect of the present Bill will be to establish a different method of appointing the executive committee than that contemplated by the Act of 1933. The committee will consist of fifteen persons, but it will not be elected by the insured members. The chairman will be appointed by the Minister, who will also appoint

¹ See THE LANCET, 1935, ii., 159.

three persons to represent employers; the Trades Unions Congress will nominate three members; five will be elected on behalf of the insured by an "electoral college" made up of persons nominated by the local authorities on behalf of the insured in their several areas; the committee will be completed by the inclusion of the three trustees for the time being of the Unified Society.

MASTERSHIP OF THE COOMBE HOSPITAL, DUBLIN

Dr. Robert H. J. Mulhall Corbet has been elected master of the Coombe Hospital in succession to Dr. T. M. Healy, whose term of office had expired. Dr. Corbet is a graduate in medicine of the University of Dublin, and a fellow both of the Royal College of Physicians of Ireland and of the Royal College of Surgeons in Ireland. He has been assistant master both of the Rotunda Hospital and of the Coombe Hospital. The term of office as master is seven years, and it is hoped that during the tenure of the new master the hospital will move into a modern, completely equipped building.

(FROM AN OCCASIONAL CORRESPONDENT)

EMERGENCY TREATMENT OF ACUTE ALCOHOLISM

Drs. L. S. Robinson and Sydney Selesnick who have to treat about 700 alcoholic patients yearly in the fifth medical service of the Boston City Hospital have devised a very rational and apparently successful method of treating the more severe cases of acute alcoholism that show coma, stupor, drowsiness, or ataxia. Study of the literature shows that the administration of carbon dioxide increases the respiratory excretion of alcohol, while administration of oxygen will save the life of rabbits that have received a dose of alcohol lethal to the controls. There is evidence that the oxygen is effective rather by speeding the oxidation of the alcohol than by relieving oxygen-want. The Boston doctors therefore have administered a mixture of 10 per cent. carbon dioxide in oxygen through an open slot mask. Blood chemistry observations were made before administration and after 30 minutes' inhalation of the mixed gases. The alcohol content of the venous blood was found to diminish more rapidly in treated patients than in controls. No carbon dioxide retention resulted from the treatment. The high lactic acid content of the blood of alcoholics was found to be unaffected by the treatment. Clinically the results were encouraging. Respiration became deep and regular almost at once. The patient changed rapidly from a cyanotic cold person to a pinkish warm one. After half an hour he would breathe normally left to himself; also he could be aroused by painful stimuli. The treatment is recommended not as routine but as emergency treatment of acute alcoholism where danger of paralysis threatens life.

SURVIVAL OF MICRO-ORGANISMS AT LOW TEMPERATURES

The increasing consumption of frozen fruits and vegetables in this country lends interest to observations made by the Bureau of Plant Industry (Dept. of Agriculture) on survival of micro-organisms at low temperatures. Twenty-six species of bacteria, yeasts and moulds were isolated from fruit that had been stored for three years at 15° F., and were transplanted to freshly made beef infusion agar adjusted to pH 7.0. These slant cultures were placed in the 16° cold-storage room at the Arlington Experiment Farm. After three months definite growth even at

this low temperature was found to have occurred in three of the transplants—all of them yeasts. Between five and seven months growth was observable in five more cultures. At the end of a year all cultures were brought into the laboratory, allowed to thaw out, and incubate at room temperature. All but 5 of the 26 species showed an "exceptionally large amount of characteristic growth" in 24 hours.

THE CAMPAIGN AGAINST VENEREAL DISEASE IN GRENOBLE

Dr. Butterlin, who is in charge of the venereal disease service of the Department of the Isère, gives an encouraging account of the progress effected in this Department since the introduction of a minor revolution in the control of prostitution and the provision of free treatment. While most of France continues to cherish hopes of the efficacy of official medical control of prostitution, the authorities of Grenoble have broken with this tradition and, after suppressing prostitution as a State-regulated profession, have provided a central venereal disease service in Grenoble itself, and five branches of this service in other parts of the Department. The Grenoble service assures the strictest secrecy and is open every evening, with one section for men and another for women. The treatment given on the spot is controlled by serological and bacteriological examinations undertaken by the Department's medical staff. Dr. Butterlin's statistics for the past six years show that, with a great rise in the number of attendances, there has been a fall in the number of new cases of syphilis and chancroid. During these six years the annual number of attendances has risen from 7000 to 27,300. In 1929, 79 syphilitic chancres were observed. This figure rose to 144 in 1930, and fell in 1931 to 115. The corresponding figures for the next three years were 38, 30, and 41. The decline in the number of chancreoids seen has been even more dramatic; from 1924 to 1929 some 15 to 25 such cases were seen every year, but during the last two years chancroid has disappeared more or less completely. The figures for gonorrhœa are less encouraging, presumably because of the notorious difficulty of diagnosing early and treating effectively the gonorrhœa of women.

THE DEATH OF PROF. WALTHER

Prof. Charles Walther, who died just before Christmas, packed into his long life most varied activities, although he was always the scientific surgeon. He brought to his studies a methodical and logical mentality which marked his actions whether they concerned research, operative technique, or administration. He was professor in the Paris faculty of medicine, chirurgien honoraire des hôpitaux, president of the International Surgical Association, and Grand Officer of the Legion of Honour. He received the Croix de Guerre for his wartime services which included the administration of two important surgical centres in Paris (the Val-de-Grâce and the Pitié). In 1918 he was elected member of the Academy of Medicine, and until 1934 he was a familiar figure in the chair at its meetings. He had much to do with the introduction of the practice of swabbing the field of operation with tincture of iodine, and he made important contributions to the study of appendicitis, nerve lesions, cancer of the tongue, and local anaesthesia with cocaine.

OBITUARY

WILLIAM COLLIER, M.D. Camb., F.R.C.P. Lond.

Now and again there appears in a city a man whose life and work make an enduring impression, who possesses that mysterious quality, prestige, a quality which depends not upon worldly success or professional acumen, but upon a subtle combination of ability and personality associated with a disinterested devotion to ideals of conduct and leadership which distinguish him from his fellow men. Such a man was Dr. William Collier, whose death on Dec. 21st is deeply mourned by all in Oxford who knew him as friend, physician, or colleague.

Collier's was an interesting life and a chance contact was responsible for his adoption of the profession which he subsequently came to practise and adorn. The youngest of five children of Henry

Collier of Stapleford, Cambridge, he was born in 1856, and after passing through Sherborne School he entered Jesus College, Cambridge, without any clear idea as to his future. The spirit of adventure which was a feature of his whole career led him to give up his academic course and to join an expedition to explore the possibilities of flooding the Sahara. In the preliminary reconnaissance by sailing ship of the northern coasts of Africa,

DR. COLLIER

Collier was afflicted by such disastrous sea-sickness that he was compelled to abandon the venture, being landed penniless at Teneriffe. Having recovered his strength he attempted to secure a return passage by a ship sailing for England, but the captain—a cautious Scot—refused a cheque, and Collier was sent ashore. From this dilemma he was extricated by a passenger who voluntarily produced the passage money and Collier returned to England and Cambridge. Here by chance he met Sir George Murray Humphry, whose advice to control his enthusiastic and adventurous spirit came to Collier as something of a shock. Humphry suggested medicine as a possible career and this advice was followed, Collier taking a pass degree, all that was possible to him after the interruption of the African adventure. His wise counsellor retained a keen interest and friendship for the young man in after years.

At King's College Hospital Collier acted as dresser to Lister who had come to London in 1876, and on qualification (in 1880) he took up the post of house physician and pathologist at the Wolverhampton General Hospital. A short experience followed in a fashionable practice in Hastings, which he found distasteful and he gladly presented himself for the post of house physician to the Radcliffe Infirmary, Oxford, to which post he was appointed in 1881, being elected a physician to the hospital in 1885, and in this year he obtained his M.D. Cambridge.

In 1886 he obtained the membership of the Royal College of Physicians to which he was elected a fellow in 1892. As a physician and teacher, while conducting his own practice, he built up a reputation as a consultant among his colleagues both in the city and county, his work being distinguished by a wisdom, sympathy, and sound judgment which were characteristic of his matured outlook on life. As a proof of the high esteem in which he was held by his colleagues he was presented, in 1929, with his portrait painted by the Hon. John Collier, an exceptionally successful likeness which is reproduced with this obituary notice.

An enthusiastic, vigorous, and far-sighted promoter of many schemes for the reform of professional, hospital, and social services, Collier was a generous opponent, quick to grasp another's point of view, and with a sense of humour which never deserted him in debate or intercourse. He once said of himself that he "had never hated any man," a rare attribute in a man who was a determined fighter in any cause which he had taken up, but an observation to the truth of which all who knew him will subscribe. One very important service which he rendered to the Radcliffe Infirmary was the successful organisation of the 2d. Contributory Scheme in 1920, the first of its kind in a county rural district, a scheme which in the past year has produced over £40,000 towards hospital services in the area. In a long, active, and useful life Collier held many posts of distinction and lived to see many of his ideas realised in practice; his memory and his keen interest in people and affairs he retained to the end, and his remarkable physical activity is evidenced by the fact that at the age of 75 he ascended the Pillar Rock in Cumberland.

Dr. Collier married Anna, daughter of the Rev. Dr. James Legge, first professor of Chinese in the University of Oxford. His widow and two daughters survive him. Of his two sons one, Dr. W. T. Collier, M.C., F.R.C.P., physician to the Radcliffe Infirmary, died at the age of 43; the other, Lieut. Martin Collier, R.N., lost his life during the war. A daughter, Dr. Ivy Collier, died in 1927.

F. G. H.

ARCHIBALD STANLEY PERCIVAL, M.A. Durh., B.Chir. Camb.

CONSULTING SURGEON, NEWCASTLE-UPON-TYNE EYE HOSPITAL

THE death occurred on Dec. 22nd at Shenley, Woking, of Mr. A. S. Percival, the ophthalmic surgeon who for some 30 years was a leading authority on many aspects, especially the mathematical ones, of his specialty.

The son of Mr. Stanley Percival of The Hermitage, Woking, he received his preliminary education at Repton, proceeded to Trinity College, Cambridge, as a science scholar, and graduated in 1884 with a first class in the Natural Sciences Tripos. He went to St. George's Hospital for his clinical training, graduated as M.B., B.Chir. Camb., and held various house appointments, including that of house surgeon at the Royal Westminster Ophthalmic Hospital. His experience there determined his future career, for shortly afterwards he was appointed ophthalmic surgeon to the Children's Hospital, Newcastle-on-Tyne, and in Newcastle he practised as ophthalmic surgeon until his retirement in 1928.

Percival was from the very beginning of his career attracted by the mathematical side of his specialty, and although all his elaborate work was in his own interest directed towards the improvement of

clinical methods and the smoothing away of difficulties both in diagnosis and treatment of ophthalmic disorders, his contributions to the subject assumed for their comprehension a mathematical knowledge and perception denied to most clinicians. Percival was always unaware that there are people who cannot read and detect at a glance the significance of elaborate equations, but his writings were mostly confined to the special journals, where the appeal was to an instructed audience. He contributed to the *Archives of Ophthalmology*, to the *Ophthalmic Review*, to the *British Journal of Ophthalmology*, as well as to the *Transactions* of the Ophthalmological Society articles on bifocal lenses and the action of prismospheres and decentred lenses; on the action and uses of prismatic combinations; on periscopic lenses; on the correction of astigmatism by tilting spherical lenses; on colour phenomena; and on decentration and oblique cylinders. To the *Transactions* of the Northumberland and Durham Medical Society he was also a frequent contributor, writing on convergent and divergent squint, errors of refraction in relation to headache, and faulty tendencies of the ocular muscles.

In 1899 he wrote his first book entitled "Optics, a Manual for Students" which showed him immediately as an original worker along the mathematical side of optics, the attempt being to arrive at the knowledge of the laws underlying observed phenomena and to devise means for the attainment of certain results. Here Percival was a direct follower of Isaac Newton, and his manual, although by the implication of its title directed to students, was really an advanced mathematical treatise going far beyond the ordinary restrictions of algebra and geometry observed in any teaching text-book. For example a knowledge of the properties of caustics is essential to a due comprehension of the theory of optical instruments, and for spherical reflectors most of those properties can be studied in the generating epicycloid. With this object the reflector is usually referred to rectangular coördinates, the first differentials of which define the position of the reflected ray and the second differentials the locus of the intersection of two consecutive rays. Percival materially simplified this complicated part of the subject by a new and ingenious application of mathematics. He published in 1913 a short volume, entitled "Geometrical Optics," which may be regarded as an expansion and simplification of the more elementary chapters of the earlier treatise, and those students who had the necessary grounding, or were not discouraged by the abundance of algebraic symbols, were rewarded by a conception of the optical problems of ophthalmology which might be of high value in ophthalmoscopic work and the correction of refractive errors. He also wrote a useful treatise on practical integration, and an elementary work on the principles of perspective in drawing.

Mr. Percival retired from practice eight years ago, returning to his native town of Woking. He married Winifred, the daughter of the late Mr. William Warner, who predeceased him by many years.

**FREDERIC HIBBERT WESTMACOTT, C.B.E.,
B.Sc. Vict., F.R.C.S. Eng.**

Colonel Westmacott, who died in Manchester on Dec. 20th, was a man of striking personality. His native town, which knew him as "Freddie" Westmacott, noted his love for the military side of medicine, and for the law and order which goes with it, and will miss his presence much. Had he

devoted himself entirely to the Army medical services he would have risen to high position, but otology and Manchester would have been poorer.

Related to Richard Westmacott whose sculpture of the Good Samaritan adorns the seal of the Manchester Royal Infirmary, Frederic Hibbert Westmacott was born in 1867 at Crumpsall Grove, Manchester. Educated at the Grammar School and at Owens College, he qualified in 1890 and became F.R.C.S. Eng. four years later. His early clinical experience was acquired at the Royal Infirmary, the Children's Hospital, Pendlebury, and the Barnes Convalescent Hospital, Cheadle. Then for a time he travelled in the East, going out on the Bibby Line s.s. *Shropshire* and joining in the Burma Expedition, for which he earned the first of his many military medals. Before returning to Manchester, having decided to adopt otology as his specialty, he spent a year in the aural clinics of Vienna; in his early days he was hampered for want of hospital beds, until in 1913 he became assistant aural surgeon to the Royal Infirmary, succeeded Sir William Milligan in 1924, and retired in 1927 on reaching the age limit. He held other posts at the Pendlebury Children's Hospital and St. John's Hospital. After retiring from hospital work he carried on a busy private practice, recently spending some of the winter months at Monaco. For the last few years his health had declined, although he was unwilling to save himself as he might have done

COLONEL WESTMACOTT

[Photograph by F. W. Schmidt]

Westmacott's military life started as a private in the (then) 2nd volunteer battalion of the Manchester Regiment, later he was transferred to the local R.A.M.C., becoming surg.-lieut. of that corps. At the outbreak of war he was registrar of the local territorial hospital, the 2nd Western General. A year later when J. W. Smith relinquished the post he became officer in charge and spent his time between this hospital and the 57th General Hospital which served in France and Italy. He was for some time A.D.M.S. at Marseilles. The size and importance of the 2nd Western, to a large extent a product of Westmacott's energy, may be realised from the 235,900 patients admitted during the war, the 107,801 medical boards held there, and the 75 medical officers who were attached to it in addition to 27 civil practitioners. In 1920 he was appointed A.D.M.S. to the reorganised 42nd (East Lancashire) Territorial Division. His quick grasp of a situation, his sense of what might be improved and how to do it, combined with his mastery of ritual never left him at a loss whether in his masonic or his military work. His capacity for enforcing obedience was a by-word and his organising capacity was seen at its best as chairman of the entertainments committee when the British Medical Association visited Manchester in

1929. It was during the work of that eventful week that he had a heart attack which made many of his friends anxious.

He received many honours. The one that he appreciated especially was that of honorary surgeon to the King conferred in 1927. He was deputy lieutenant of the County of Lancaster, and Knight of Grace of the Order of St. John of Jerusalem. He was appointed C.B.E. in 1919. In 1904 he married Margaret Carlota, third daughter of Alexander Howden, who survives him.

An old friend writes: "Though holding decided views which he did not hesitate to advocate forcibly yet his obvious sincerity and his genial manner assisted in overcoming opposition, so that Westmacott usually succeeded in obtaining his own way. A dogged perseverance obtained most of the objectives upon which he had set his heart. His career as a medical student had not been brilliant and fellow students smiled when he announced his intention of taking the F.R.C.S., yet after a slight disappointment at the primary examination he confounded his critics by passing the final at the first attempt. Another goal he desired was to be A.D.M.S.—the highest office in the A.M.S. attainable by a non-regular—and in the later years of the war he was appointed A.D.M.S. to the Marseilles area and the 42nd Division. He was undoubtedly a great organiser and administrator, first as registrar and O.C. of the 2nd General Western Hospital and afterwards as O.C. of the 57th B.G.H. in France. His knowledge of French and German proved most useful in the early days of the 2nd Western, when so many wounded Belgians and German prisoners-of-war were admitted. His organisation of entertainments at the B.M.A. Manchester meeting of 1902 was so well remembered that in 1929 all the committees dealing with entertainments and transport were combined under his chairmanship. First-aid and ambulance work always had a great attraction for him; his experience as a judge of competitions between ambulance teams must have been unique. Westmacott had many social interests and engagements into which he entered with untiring energy. He enjoyed life to the full and will be sadly missed by a wide circle of friends."

**ARTHUR EDWARD GILES, M.D., M.R.C.P. Lond.,
F.R.C.S. Edin.**

CONSULTING SURGEON, CHELSEA HOSPITAL FOR WOMEN

WE regret to announce the death at Welwyn, Herts, on Dec. 26th, of Mr. A. E. Giles, the well-known surgeon and gynaecologist.

Arthur Edward Giles was the son of Mr. Samuel Giles of Bombay, where he was born in 1864. He had a varied preliminary education, being a student at the City of London School, the Havre Lycée, and the Manchester Grammar School, while he completed his medical training at Owens College, Manchester, where he entered in 1883. At Owens College he was Platt physiological scholar; he graduated as M.B., Ch.B. Vict. in 1888, and M.B. Lond. in 1891, securing first-class honours in obstetric and forensic medicine. In 1892 he proceeded to the M.D. Lond., qualifying for the gold medal, and then undertook a long course of post-graduate work in Berlin, Vienna, and Paris. In 1893 he took the diploma of M.R.C.P. Lond., and a little later that of F.R.C.S. Edin. After holding residential posts at the Manchester Royal Infirmary and the Crumpsall Hospital, Manchester, and the General Lying-in Hospital, Lambeth, Giles secured in succession appointments to the staffs of the St.

Pancras and Northern Dispensary, the Chelsea Hospital for Women, the Prince of Wales's General Hospital, Tottenham, and the Marylebone Dispensary, and by his strenuous and enthusiastic work he made for himself a prominent position as a gynaecological surgeon. His connexion with the Chelsea Hospital for Women was a very long and valuable one. He was elected on the staff of the institution as assistant surgeon over forty years ago, and was consultant surgeon at his death. Through his work here he became a recognised authority on the technique of gynaecological surgery—possibly not so widely recognised as he deserved, for he was a great clinician.

As a writer Giles at the earlier stages of his career was profuse but practical. He wrote the article on gynaecological operations in Carson's "Operative Surgery," and that on hysterectomy in Eden and Lockyer's "System of Gynaecology." It would serve no purpose to enumerate the many clinical articles which he contributed at various times to our own pages and those of our contemporaries, but the communications generally arose from experiences in his varied institutional practice and had the stamp of personal knowledge. Early in his career he participated with Sir John Bland-Sutton in the production of a book which ran through some nine or ten editions and the teaching of which is still essentially sound. This book—the "Diseases of Women, a Handbook for Students and Practitioners"—set out to relate facts and describe methods in connexion with gynaecology in such a way that students might find the information valuable in their training and practitioners realise the advantages to their patients that followed prompt and proper surgical treatment. The book laid itself

MR. GILES

(Photograph by Histed)

open, despite its title, to being largely a manual of operative surgery, so slight was the stress laid on the value of medical treatment, and in other directions did not meet with universal approval, but the personal opinions were honestly given, and the teaching, within its limitations, was seen to be sound.

In recent years Giles took a deep interest in two subjects loosely related to each other—namely, the occurrence of sterility in woman and the need for medical teaching on birth control. In a short book on sterility Giles summarised much of the accepted knowledge on the matter, and attempted to determine the percentage of cases in which where a marriage had been sterile the fault lay with the male. He was only able to show, however, how difficult it must be to arrive at any certain conclusions, though he thought that the husband might be at fault in from 10 to 50 per cent. of the cases, a figure which clearly has little informative value. He estimated that the proportion of sterile marriages in this country

in the era succeeding the war was 10 per cent. for the working population and 16 per cent. for the leisured classes, and he closed his monograph, which contained a number of original observations, with a pathological and clinical classification of the causes of the condition. His views on birth control were made known in an address delivered before the Manchester Medico-Chirurgical Society (vide *THE LANCET*, 1927, ii., 165) in which the medical and gynaecological grounds for birth control were adequately set out and a clear description was given of the methods to be adopted. His general conclusion was to the effect that birth control being a necessity in certain circumstances, and expedient in a few cases, the medical profession should lay down its indications and point out its limitations.

During the war Giles served with the rank of major in the R.A.M.C., and was surgeon in charge of the Anglo-French military hospital at Tréport in 1915, and civil surgeon to the Hampstead military hospital in the following years. At Tréport he suffered from an acute septicæmia following an accidental wound while operating at Lady Murray's hospital. At the close of hostilities he went to live at Welwyn, where for many years he had had a week-end cottage, and was already consulting surgeon to the Queen Victoria Cottage Hospital. His skill as a surgeon and his unvarying kindness and courtesy to the patients greatly increased the utility and reputation of this small institution, and to the end of his life he took an interest in its working. While he still practised from his London address he lived in Welwyn, and was at the beck and call of the whole community in a consulting or operative capacity, going to the hospital at any hour of the night in response to calls. The new building of the hospital was opened in 1934 by the Duchess of York, and he performed the first operation which took place in its wards. And when he became ill only shortly before Christmas he entered a private ward of the hospital and died there on Dec. 26th, mourned by the whole neighbourhood.

Giles was consulting gynaecological surgeon to the Prince of Wales's Hospital, to the Chelsea Hospital, and the Sutton and Wood Green Hospitals. He had served as president of the section of obstetrics and gynaecology in the Royal Society of Medicine, and was a vice-chairman of the council of the East London Hospital. He was a past master of the Drapers Company, and music was among his wide interests; one of his compositions was played recently at a conversazione at the Royal Society of Medicine. He married May Hartree, daughter of the late Mr. A. A. Tindall.

MEDICINE AND THE LAW

Agranulocytosis and Amidopyrin

AN inquest on another case of suspected agranulocytosis was held at St. Pancras Coroner's Court on Dec. 27th, within a week of that recorded in our last issue. The victim was a man aged 47 who had been in poor health for two years and had been treated for fibrositis by diathermy, but not, according to his widow, by drugs until two months ago when he had bought a bottle containing 100 five-grain tablets of Novalgin. Between them husband and wife had consumed 91 tablets, the husband accounting for about 60. The widow said that she had not mentioned the tablets before because she did not think that the drug had anything to do with her

husband's symptoms—i.e., shivering and sore-throat. Sir Bernard Spilsbury said that the microscopical changes in the body were remarkably like those of the previous case, but that it was difficult post mortem to prove any effects upon the blood. The striking absence at the autopsy of any marked change in the organs had made him suspicious. He was now satisfied that death was attributable to the drug. The coroner, Dr. Bentley Purchase, said that from the beginning the case had struck him by its similarity to the other, but it was not until the widow had mentioned novalgin that any connexion was revealed. Pyramidon and novalgin, though differing in their constitution, contained a common chemical group (pyrazolon). He again emphasised that though this type of drug was valuable its use needed great care; he proposed to refer the case to the Poisons Board and returned a verdict of death by misadventure.

Sale of Dentist's Practice

The sale of a dentist's practice in Wimpole-street has raised a doubtful point of income-tax law. The purchase agreement specified a "primary" price of £15,000, subject to variation as subsequently explained. Of this sum £5000 was to be paid forthwith; the purchaser was to pay the balance by annual payments over the next ten years in the form of 25 per cent. of the net profits of the year; these ten-year payments were to increase or diminish the "primary" price of £15,000 according as they came to more or less than £10,000. They were to be regarded as capital sums paid in respect of the purchase price. This arrangement gave the buyer the advantage that he would be paying according to the actual value of the practice. He sought the further advantage of deducting these annual payments from income for the purpose of his super-tax returns. In a particular tax year the payment turned out to be £886. He claimed that this was in the nature of income and not a capital sum, and that it could therefore be deducted in ascertaining his own taxable income. The Special Commissioners agreed and allowed the deduction. So did Mr. Justice Finlay. The Court of Appeal, however, took a different view last month. The Masters of the Rolls said the question was whether the purchase agreement contemplated the payment of a sum of money (payable in instalments or otherwise) or an annuity. The agreement fixed £15,000 as the purchase price from beginning to end; the ten-year percentage payments might have the effect of varying the total of this lump sum, but they did not alter the legal position. They were not annuities but instalments of a definite lump-sum price. It followed that the £886 could not be treated as income. It was capital and it could not be deducted from income for purposes of super-tax return. And now the experts who assist professional men over the purchase of a practice will perhaps turn back to the idea of payment in the form of annuities. It will depend on whether they are advising a prospective buyer or a prospective seller. The seller in the Wimpole-street case would probably have been surprised if income-tax had been claimed from him on the instalments of the purchase price.

ROYAL PORTSMOUTH HOSPITAL—Over £79,000 has been spent upon extensions to this hospital. Subscriptions received during the year amounted to over £7000 bringing the total sum collected to over £75,000, while about £10,000 more has been promised. Three of the wards of the new block have been in occupation for some months.

CORRESPONDENCE

ROYAL MEDICAL BENEVOLENT FUND

To the Editor of THE LANCET

SIR,—I have once more the pleasant duty of thanking you for the help you have given the committee of the Royal Medical Benevolent Fund in respect to the Xmas gifts for our beneficiaries.

The response of our medical brethren has been very prompt and generous, the amount raised is £819 4s. 3d., an increase of £148 9s. over last year.

The replies of the beneficiaries are, many of them, pathetic, indicating how this gift has been most useful in respect to fuel, and other Xmas comforts.

Believe me,

Yours sincerely,

Wimpole-street, W., Jan. 1st, 1936. THOS. BARLOW.

PAIN AND EUTHANASIA

To the Editor of THE LANCET

SIR,—You have been admonished by Dr. Piney for opening your columns to the discussion of voluntary euthanasia. There is little doubt that the general practitioner, on whose shoulders falls the responsibility of seeing these unfortunate patients through the penultimate stage of their illness, and who can speak with authority on the matter, is deeply interested in the subject. There is, moreover, a large section of the lay public who read THE LANCET and look for intelligent guidance from medical men on a subject which concerns the community as a whole.

Mr. Bankart and Prof. Rogers remind the medical profession of another palliative measure to relieve pain, namely, chordotomy, but all practical surgeons are familiar with this procedure, and equally familiar with the extremely limited scope of this operation. Their reminder is given with a bland assurance which is apt to mislead, and to leave the impression that with chordotomy the problem is solved. Only too well we know that for cancer of the tongue and pharynx, of the thyroid and larynx, and of that terrible disease, cancer of the œsophagus, chordotomy is impracticable.

There is a widespread belief that incurable and lingering cases of fatal disease are ministered to by trained and sympathetic nurses and by every resource that can be devised by medical science in hospitals or homes for incurables. The hideous truth is that the majority of these cases are discharged from hospital and terminate their pitiable existence in working-class homes or even in slum dwellings. Even in hospitals, when all cases which can be given effective palliative treatment have been discounted, there still remains a residuum, for whom alone this Bill is designed, the relief of whose sufferings is beyond the skill of our profession.

The root of the matter is not the mental distress of relatives, nor the abstract conscientious scruples of those who are not themselves suffering pain; it is for these cases, which are alleged to be few in number, that a method of escape from intolerable pain of body and distress of mind is sought. How few or how many these cases may be, remains to be seen, but I suggest that the testimony of the family doctor is the most valuable on this point. It is marvellous with what equanimity we bear the misfortunes of others, comforting them with the spectacle of the Thief on the Cross, the duration of whose sufferings, by the by, was measured in hours not in weeks or even months, and whose punishment for his crimes

was in accordance with the code of justice that obtained 2000 years ago.

I am, Sir, yours faithfully,

H. H. GREENWOOD,

Member of the Consultative Council of the Voluntary Euthanasia Legalisation Society.

Swindon, Dec. 30th, 1935.

LORD NUFFIELD'S GIFT

To the Editor of THE LANCET

SIR,—Lord Nuffield, it will be remembered, has already done great things for cripples. First came his magnificent gift of £70,000 for the rebuilding of the Wingfield-Morris Orthopædic Hospital in 1933; then early in 1935 he gave £60,000 to New Zealand, and soon after £50,000 to Australia, toward the discovery and treatment of children crippled or attacked by some crippling disability. For a long time Lord Nuffield has been anxious to help forward this work in Great Britain, in order that in every area adequate provision may be made for the early and efficient orthopædic treatment of every child, adolescent, or adult in need of it. And now, as recorded in your last issue, he has given the sum of £125,000 for this purpose. The major part of this sum will be allocated to a Lord Nuffield Central Fund which is to be applied at the discretion of the trustees during the next four or five years to develop the discovery, cure, and care of cripples in the various districts where this work is not being at present specifically undertaken, or is being undertaken on an entirely inadequate scale. Much credit is due to the Central Council for the Care of Cripples that many parts of the country are already well organised. But there are districts where a great deal remains to be done; their requirements will be explored and recommendations made to the trustees of the Fund for grants in aid of new work.

Lord Nuffield is devoting another part of his benefaction to the endowment of a scholarship in orthopædic surgery; this is to be tenable for two years at the Wingfield-Morris Orthopædic Hospital, Headington, Oxford, with a travel period of three months to follow. He hopes this will attract and be of value to young surgeons who are specialising in orthopædic surgery. It will provide an opportunity of working in an orthopædic hospital of the most modern design, and with a well-established outside organisation for the early discovery of potential cripples, their out-patient treatment, and their after-care. It is proposed that the regius professor of medicine of Oxford and the president of the British Orthopædic Association shall be on the small electoral body for this scholarship.

I am, Sir, yours faithfully,

Oxford, Dec. 27th, 1935. G. R. GIRDLESTONE.

NARCO-ANALYSIS

To the Editor of THE LANCET

SIR,—Recent allusions in the newspapers to the use in America of "truth serum" ignore the fact that certain drugs facilitate not only the divulgence of carefully guarded secrets but also the restoration of forgotten memories. Such possibilities are of interest not only to the criminologist but also to the psychiatrist. The successful combination of narcosis with psychotherapy would be a real advance in mental treatment. Many writers have referred to the value of such a combination, but so far as I know the

narcopsychological approach has not progressed beyond the method of simple suggestion. This is due to the stupefying effect of the narcotics employed.

In an attempt to extend this line of investigation, I have experimented with Somnifaine, Sodium amytal, Sodium soneryl, Nembutal, and a combination of Evipan with Avertin. I find nembutal the most effective in producing sedation with the minimum of confusion. I have evolved a technique which I call "narco-analysis."

The usual routine examination is made and the patient is then prepared as for a general anæsthetic. A state of light narcosis is produced by the slow intravenous injection of a 2½ per cent. solution of nembutal. During the injection every effort is made to make the patient amenable to hypnotic analysis. The resulting willingness of the patient, the release of inhibitions, and the ability to recall experience, recent or remote, makes analysis relatively simple and speedy. In an hour the physician obtains a quantity of relevant information which he would not have obtained in a month by ordinary methods. A true hypnotic state is induced, and this facilitates suggestion, which must be given with great care and forethought. It is directed in all cases towards restoring the contact of the patient with the realities of his life and environment.

The séance is prolonged for about half an hour and then merged into deep narcosis by a further injection of nembutal. The same technique can be repeated if necessary on successive days. The following is a typical case:—

A single woman, aged 37, was brought to hospital for temporary treatment under Section 5 of the Mental Treatment Act, 1930. The recommendations stated that for six weeks she had been abnormally depressed, deluded as to her identity, and grossly disorientated. A week after admission her condition was unchanged. Narco-analysis was begun on the eighth day. She at once became calm and coöperative, and recalled significant forgotten memories which were of value in re-establishing environmental contact. Two séances secured a total of 50 hours' sleep. On waking she described a dream symbolising her recovery. From this moment she remained bright, cheerful, and amenable. A fortnight later she was discharged recovered.

This case is illustrative of some 130 treated by the same method. The results have been encouraging in all of them, and I hope in due course to report the results in detail. I am indebted to Dr. P. W. Bedford, medical superintendent of this hospital, for permission to publish the above case.

I am, Sir, yours faithfully,

J. STEPHEN HORSLEY,
Senior Assistant Medical Officer,
Dorset Mental Hospital.

Dec. 10th, 1935.

PLEURAL SHOCK AND/OR AIR EMBOLISM

To the Editor of THE LANCET

SIR,—Whilst agreeing with the conclusion reached in the editorial article in THE LANCET of Dec. 28th—namely, that this accident of artificial pneumothorax may well be avoided altogether by careful technique—I do not think the methods suggested are necessary or even wise, nor do I think the usual mechanism of air embolism can be that which you describe. As this complication occurs more frequently during refills than during inductions, it does not seem very likely that it is caused by puncture of the lung or of an adhesion, both of which must take place much more frequently during the first attempted injection than later. Even from a mechanical point of view this seems an unlikely accident. Most apparatus is

reasonably airtight, and the volume of air contained in the accessory tubing must be a good deal less than 75 c.cm., but let us suppose for the sake of argument that this large volume of air is contained in the tubing, and let us further suppose that the suction in the vein entered is equal to a pressure of 13 cm. of water or 1 cm. of mercury. It is of course most unlikely to be so high, as experience of manometer readings shows that records of this order are never obtained except when the point of the needle is in the pleural cavity. Experience also shows that there is considerable resistance even in a fairly wide bore needle, which damps manometer fluctuations and obstructs the rapid flow of air, but let us ignore this resistance. The volume of the air therefore in the tubing will expand under the reduced pressure,

and a volume $75 \times \frac{76}{75} - 75 = 1$ c.cm. of air will be free to enter the vein. Is it possible for so small a quantity of air, after being churned up and partly absorbed by the blood in the heart and great vessels, to cause serious symptoms? We have considered an extreme possibility; in ordinary circumstances the volume which could in this way enter the vein would be far less, and moreover would enter slowly owing to friction in the needle. I cannot believe that this is the mechanism of air embolism, provided of course that air from the storage compartment is not allowed to flow through the needle before assurance is made that the point is in the pleural cavity.

On the other hand, during either inductions or refills adhesions may be torn by the retracting lung. These are, moreover, more likely to contain lung tissue when lacerated by the powerful retraction of an already partly collapsed lung, that is during refills, than when severed by the comparatively feeble pull of the almost fully expanded lung, that is during inductions. Spontaneous pneumothorax complicating artificial pneumothorax and due to laceration of an adhesion is not an infrequent happening. It is, therefore, easy to conceive of air embolism being caused by a tearing of an adhesion containing a branch of the vein, and thus allowing air from the pleural cavity to enter the circulation freely, in just the same way that air may flow from the air passages into the pleural cavity, should the adhesions contain portions of the lung in communication therewith.

The prevention of air embolism is therefore, I hold, the adoption of a technique which does not produce extreme tension in any adhesion, unless this is felt to be desirable after a careful consideration of all aspects and of all dangers, and then taking care to ensure that this tension is not suddenly applied.

I am, Sir, yours faithfully,

C. O. S. BLYTH BROOKE,
Tuberculosis Officer, Borough of Finsbury.
Dec. 23rd, 1935.

ATEBRIN POISONING

To the Editor of THE LANCET

SIR,—I read with interest the report by Drs. Fernando and Wijerama of a fatal case of Atebrin poisoning, published in your issue of Nov. 9th. The following case, admitted to the Mysore Government Mental Hospital, Bangalore, presented neurological and psychiatric symptoms, following the administration of atebrin, which may be worthy of notice:—

The patient, a flabby male aged 32, was referred on Nov. 19th, 1935, by his medical attendant for protective

observation because he showed acute maniacal symptoms. He had been having daily attacks of malaria for the past three weeks, and quinine administered during the first week had given no relief. During the eight days before admission he had two pills of atabrin daily, and three injections of atabrin mussonate. Fever had subsided, but 24 hours before admission he had become destructive and violent.

Physical Examination.—The patient was very restless, throwing about bed-clothes, and had to be restrained. He was deeply jaundiced. The liver and spleen were not palpable, and there was no evidence of hepatic pain; the tongue was thickly coated and the breath foul. The pulse-rate was rapid, 120 per minute, of low tension, irregular, missing one in every 10–12 beats. The apex-beat was within the nipple line, but a soft uncondensed, systolic murmur replaced the first sound in the apical and pulmonary areas. The pupils were moderately dilated and reactive, but there were coarse, rapid, nystagmoid jerks, about 16 per minute, making it almost impossible for the patient to fixate. He had fine tremors of the tongue and hands. Speech was slow and hesitating, but there was no dysphasia. The reflexes were sluggish except the knee-jerk, which was + + + +. No Babinski sign.

Mental Examination.—Restless; psychomotor activity increased of both the small and large joints; disorientated with reference to time and space; he would shout that snakes and fantastic animals were crawling on the floor,

and reacted to such visual hallucinations with fear, violence, and emotional instability.

Laboratory Findings.—No malarial parasites found. Urine scanty, reaction acid, no sugar or albumen found; no bile pigments or atabrin were present. Faeces foul-smelling, but yellow and not clay-coloured.

Progress and Treatment.—The patient was given immediately a magnesium sulphate enema, and on account of his restless and non-coöperative state, a paraldehyde enema. He passed a quieter night. He was put on daily injections of cyclotropin (five days) and strychnine gr. 1/20 b.d., and general treatment like daily warm sponging. His mental symptoms cleared up within three days and his jaundice on the seventh day. On Nov. 29th, 11 days after admission, he was discharged recovered, though somewhat weak.

The case is of interest as showing mental symptoms suggestive of delirium tremens (the patient was a total abstainer) and neurological symptoms suggestive of an involvement of the labyrinthine cerebellar extrapyramidal pathways. I have seen several cases of santonin poisoning with similar symptoms.

I am, Sir, yours faithfully,

M. V. GOVINDASWAMY,
Superintendent, Mental Hospital,
Bangalore.

Dec. 12th, 1935.

PUBLIC HEALTH

The Two-Shift System

THE two-shift system of employment was legalised in 1920, but the trade depression has discouraged many employers from introducing it. Two shifts of eight hours each are worked between 6 A.M. and 10 P.M., so that machinery can be kept running for 88 hours a week, though no worker is employed for more than 48 hours. A report issued in 1928¹ contrasted the output, lost time, and labour turnover of the same workers employed on either system. The hourly output of the shift workers was greater, the voluntary rest pauses fewer, although, as the working hours were shorter, the output per worker was 4 per cent. less than in the ordinary system. An employer who changed from day-work with a 48-hour working week to shift-work of 82 hours might expect an increase of output per machine of over 92 per cent. There was no definite advantage in either system with regard to the sickness experienced by the workers.

At the present time 36,000 women and young persons are working in double shifts. The system has been very carefully examined by a departmental committee, particular attention being paid to the health and the social and home life of the workers. The single disadvantage, about which there has been no general complaint, is the relative lateness of certain of the meal-times. In the morning shift, for example, the midday meal cannot be taken until 2 P.M. The advantages are the shorter hours, the greater leisure during the day, and the increased opportunities of fresh air and exercise. These led the committee to the conclusion that the system did not in any way injure the health of the workers.

Moving the second reading of the Employment of Women and Young Persons Bill in the House of Commons on Dec. 17th, Mr. Geoffrey Lloyd, Under-Secretary of the Home Office, said that the Bill was to continue this scheme with certain modifications and safeguards. The rejection of the Bill was moved

by Mr. Rhys Davies because of the increasing liability of young persons to accidents at their work, due to the greater speed of working. He objected to the double-shift system on this ground and because it was contrary to the social habits of the British people. The medical aspects of the system were discussed by Dr. Howitt, who had served as an adviser on the committee. He assured the House that the system could have no adverse effect upon the health of the workers. This was the opinion of the great majority of the doctors, welfare workers, factory inspectors, and supervisors, and also of the workers themselves, not only in evidence before the committee, but also in answer to inquiries conducted in the factories. The chief medical inspector had assured them that he had not had a single complaint from any worker on a double shift about the system. The scheme eliminated the long periods of overtime which were particularly bad for women and young persons. Another advantage was the greater supervision and the higher standard of amenities which the Home Secretary demanded before he would grant an order. The workers appreciated the break in the monotony of factory work given by the shorter hours and particularly the alternate free week-ends. Mr. Hollins (Lab., Stoke-on-Trent) however was able to cite some evidence that double-shift workers suffered more than day workers from headache and respiratory diseases. After the Home Secretary had given an undertaking that the Government would appoint an advisory committee, the second reading of the Bill was carried.

HUDDESFIELD MUNICIPAL HOSPITAL.—Huddersfield health committee are proposing to build a new municipal hospital in the town which, it is estimated, will cost about £100,000.

LEITH HOSPITAL.—The managers of this hospital have issued an appeal for £60,000 for the reconstruction of its buildings. The existing medical block is to be demolished and a five-storey block erected which will contain male and female medical wards and administrative and sun-ray departments.

¹The Two-Shift System in Certain Factories. By Mary Smith and M. D. Vernon. Industrial Fatigue Research Board. Report No. 47. H.M. Stationery Office, 1928. See THE LANCET, 1928, i., 740.

MEDICAL NEWS

University of Cambridge

At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B. AND B.CHIR.

Part I., Surgery, Midwifery, and Gynaecology.—L. J. Bacon, R. G. Bickford, R. A. Binning, G. L. Broderick, S. C. Buck, W. A. Burnett, R. S. Castle, E. M. Darmady, R. B. Davis, J. Diver, F. S. A. Doran, E. W. Dorrell, R. C. Droop, C. H. C. Ferguson, T. D. Fraser, I. N. Fulton, B. S. C. Gaster, M. H. Harding, E. W. Hart, F. E. S. Hatfield, C. M. Heath, A. L. Jackson, D. D. Keall, R. G. M. Keeling, J. W. Landells, D. C. Lavender, A. B. Lintott, L. N. G. Lytton, J. MacKellar, F. C. Maddox, D. N. Matthews, H. K. Meller, J. S. Minnett, T. J. Morton, B. C. M. Palmer, J. W. Parks, W. J. E. Phillips, G. C. L. Pile, J. M. Ranking, G. R. Rawlings, G. Rigby-Jones, O. N. Roussel, H. P. Ruffell Smith, R. S. Saxton, D. R. Seaton, R. H. A. Swain, W. H. Valentine, J. H. Ward, S. Ward, D. J. Watterson, A. S. Wigfield, J. R. C. Williams, H. T. H. Wilson, J. R. J. Winter, H. R. Wynne, B. J. Travers, E. H. Western, E. L. Willis, and E. M. Wright.

Part II., Principles and Practice of Physic, Pathology, and Pharmacology.—L. J. Bacon, W. M. Beattie, N. B. Betts, K. O. Black, A. C. Blandy, R. E. Bonham-Carter, F. Braithwaite, G. L. Broderick, A. F. Bryson, W. T. Cooke, E. M. Darmady, D. H. Davies, H. S. Davis, C. A. Dowling, E. D. Ewing, C. U. Gregson, G. N. St. J. Hallett, J. W. Hannay, C. Hardwick, J. R. G. Harris, A. E. M. Hartley, N. T. Holden, C. S. Humphries, H. D. Johnson, J. R. Kerr, J. W. Lacey, D. C. Lavender, J. F. Lown, K. G. F. Mackenzie, I. W. MacKichan, D. N. Matthews, S. G. Mayer, R. S. Morris, J. R. Owen, R. J. Porter, C. N. Pulvertaft, C. G. Rob, A. G. Salaman, D. S. Scott, P. G. Scott, J. A. Seymour-Jones, A. F. Stallard, F. Stansfield, W. H. Valentine, H. J. Wallace, B. L. Williams, J. R. J. Winter, M. Ball, S. L. Bhatia, E. L. Willis, and W. F. Young.

University of London

At recent examinations the following candidates were successful:—

M.S.

Branch I. (Surgery).—T. W. Mimpriss, St. Thomas's Hosp.

Branch III. (Ophthalmology).—Jean M. Dollar, Royal Free Hosp.

Branch IV. (Laryngology, Otolaryngology, and Rhinology).—W. H. Bradbeer, Guy's Hosp.

DIPLOMAS IN CLINICAL PATHOLOGY

D. H. Haler, King's Coll. Hosp. (external diploma); and A. A. Razzak, Middlesex Hosp. (academic post-graduate diploma).

University of Durham

On Dec. 21st at the College of Medicine, Newcastle, the following degrees and diplomas were conferred:—

M.B., B.S.—K. G. Scott Bavidge, F. W. Boon, M. J. Bruno, A. W. Chester, H. P. Clark, Dorothy M. Clarkson, J. Dagg, C. W. Elphick, W. A. S. Falla, S. Hurwitz, G. B. Jamieson, Jean D. McKellar, B. de F. Parris a Rosenbloom, T. A. Shaw, and M. Taws.

B.Hy.—Edna T. Everdell, Dorothy D. Nichol, and Eleanor Patterson.

D.P.H.—E. G. Brewis, Edna T. Everdell, Dorothy D. Nichol, Eleanor Patterson, and Agnes A. Schofield Russell.

L.D.S.—F. N. Hutchinson Gargett, E. M. Pickering, and W. Robson.

University of Edinburgh

On Dec. 20th the following degrees and diploma were conferred:—

M.D.—John Bennet, B. S. Bindra (in absentia), †John Douglas, E. H. Duil, †H. J. Gibson, †Israel Gordon (in absentia), †J. J. B. Martin (in absentia), H. S. E. Murray, †D. C. Osborne, †T. M. J. Stewart, J. L. Swanston, *Mary B. Walker, and John White (in absentia).

M.Ch.—†Ian Aird.

* Awarded gold medal for thesis. † Highly commended for thesis. ‡ Commended for thesis.

M.B., Ch.B.—A. F. H. Aeria, C. H. Bannerman, E. W. Q. Bannerman, E. G. Barnes, W. M. Burgess, A. P. Burnett, R. J. C. Campbell, T. M. S. Clark, A. H. Crichton, Winifred M. Dempster, Harold Ferguson, W. G. S. Harden, H. O. Howat, R. P. Jack, J. M. M. Jamieson, P. M. Kirkwood, R. K. M'All, T. A. MacGibbon, A. I. M'Kendrick, D. S. M'Kenzie, Duncan MacKenzie, K. I. E. Macleod, A. B. Milligan, T. R. N. Parhar, R. G. Parker, Isabella A. Purdie, A. S. L. Rae, A. N. Reid, R. J. S. Smith, Robert Somerville, Alfred Stern, H. H. Stott, and G. L. Walker.

D.P.H.—T. A. Don.

Dr. Mary Walker was awarded the gold medal for her thesis on myasthenia gravis, which incorporated her discovery of the action of physostigmine and prostigmin in its treatment.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

Surgery.—W. C. Heunis, Lond. Hosp.; J. M. Lea, Guy's Hosp.; and N. O. Lucas, Univ. of Oxford and Guy's Hosp.

Medicine.—C. W. Mills, St. Bart's Hosp.; J. F. O'Malley, Guy's Hosp.; and G. M. Williams, London Hosp.

Forensic Medicine.—C. W. Mills, St. Bart's Hosp.; and J. F. O'Malley, Guy's Hosp.

Midwifery.—G. K. Coombes, King's Coll. Hosp.; B. Anderson, Charing Cross Hosp.; and H. Bentovim, Univ. of Manch.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery: B. Anderson, N. O. Lucas, and G. M. Williams.

Queen's University, Belfast

On Dec. 21st the following degrees were conferred:—

M.D.—J. C. C. Crawford, J. V. Hurford, and T. W. H. Weir (with commendation); and E. A. J. Byrne (in absentia).

M.B., B.Ch., B.A.O.—J. E. Morison (second class honours); F. C. Banks, J. P. Cosgrove, W. W. Davey, W. McKeown, C. C. D. Martin, B. V. McGarry, W. D. Miles, N. J. Y. Simpson, Louise Skillen, and W. McL. E. Topping.

L.D.S.—I. St. C. Alderdice and S. Hill.

University of St. Andrews

At a meeting of the court on Dec. 26th Mr. R. C. Alexander was appointed professor of surgery and Mr. R. S. Melville lecturer in clinical surgery.

Mr. Alexander was educated at the University of Edinburgh where he graduated in arts, and in 1908 obtained the degree of M.B. with honours. After further study in Paris he returned to Edinburgh, where he became a fellow of the Royal College of Surgeons in 1911, and was appointed assistant surgeon to the Chalmers Hospital. In 1921 he went to Dundee where he became surgeon to the Royal Infirmary and lecturer in clinical surgery at the University of St. Andrews. During the war he served with the British Expeditionary Force, holding rank as major in the R.A.M.C. He is a contributor to the Encyclopaedia of Medicine, and has written on the surgery of many different conditions, including cysts of the liver, adenoma of the bile-ducts, and anuria. He is an examiner in operative surgery and surgical pathology for the Royal College of Surgeons of Edinburgh, and consulting surgeon to the Memorial Cottage Hospital, St. Andrews, and the County and City of Perth Royal Infirmary.

Regulation of Warfare

An international committee of the Congress of Military Medicine and Pharmacy has for some time been considering the regulation of warfare, and a conference to discuss the subject will meet at Monaco from Feb. 10th to 12th. Prof. Dehousse, of Liège, will describe the present state of the law towards war, especially as regards the protection of the civilian population, and Dr. Voncken, director of the Office International de Documentation de Médecine Militaire, will discuss ambulance services in the war of the future. The third purpose of the meeting will be the establishment of an Association Universelle pour la Protection Internationale de l'Humanité. Further information may be had from Dr. Voncken, Quai de Plaisance, Monaco.

Conference on Mental Health

The National Council for Mental Hygiene is holding its fourth biennial conference on mental health at the Central Hall, Westminster, from Jan. 23rd to 25th. The Duke of Kent, president of the council, will open the conference and will take the chair at the first session when Lord Allen of Hurtwood and Dr. William Brown will discuss mental hygiene and international relations. Other subjects and speakers which have been announced are: the organisation and correlation of mental health services in local areas (Prof. R. M. F. Picken and Dr. T. Saxty Good); problems of marriage and the establishment of courts of domestic relations (Dr. Helen Boyle); and the priest and the doctor in the treatment of nervous and mental disorders (Dr. H. Crichton-Miller). There will be a symposium on education for living, comprising mental health, those first eight years (Dr. R. G. Gordon, Dr. Maria Montessori); "moulding" the mind, eight to fourteen (Dr. Emanuel Miller); and the "finished" product, fourteen onwards. The secretary of the council may be addressed at 78, Chandos House, Palmer-street, London, S.W.1.

Royal Institution of Great Britain

On Jan. 31st the Friday evening discourse will be given at 9 P.M. by Prof. Edward Mellanby, F.R.S., who will speak on recent advances in the treatment of disease. On March 10th, 17th, 24th, and 31st, at 5.15 P.M., he will give a series of lectures on drug-like actions of some foods. The address of the institution is 21, Albemarle-street, London, W.1.

Lectures on Industrial Law

The Industrial Welfare Society is arranging a course of lectures which will give those interested in administrative work in industry and commerce a practical knowledge of the branches of the law which they will need. The lectures will be given by Mr. H. Samuels on Wednesdays from Jan. 22nd at the headquarters of the society, 14, Hobart-place, Westminster, S.W., at 6.30 P.M.

British Ambulance Unit in Abyssinia

This unit, which was originally planned for work in the Ogaden, has, at the express wish of the Emperor, now gone to Dessie. It thus becomes the chief Red Cross unit for the northern armies in Abyssinia. This change has incurred heavy additional expenditure. Donations may be sent to Sir Arthur Stanley, British Red Cross Society, 14, Grosvenor-crescent, London, S.W.1, or to the hon. treasurer of the British Ambulance Service in Ethiopia (Mr. A. W. Tuke), Barclays Bank, 54, Lombard-street, E.C.2.

Fellowship of Medicine and Post-Graduate Medical Association

The following all-day courses will be available during the first two months of this year: cardiology at the National Hospital for Diseases of the Heart (Jan. 13th to 24th); proctology at St. Mark's Hospital (Feb. 3rd to 8th); gynaecology at the Chelsea Hospital for Women (Feb. 10th to 22nd). Week-end courses will be held in heart and lung diseases at the Royal Chest Hospital (Jan. 18th and 19th); in physical medicine at the St. John Clinic and Institute of Physical Medicine (Feb. 8th and 9th); in children's diseases, Princess Elizabeth of York Hospital (Feb. 22nd and 23rd). On Tuesdays and Thursdays at 8.30 P.M., from Jan. 14th to March 5th, surgical tutorial classes (specially suitable for F.R.C.S. candidates) will be given at the National Temperance Hospital, and an evening course in anatomy and physiology (in preparation for the primary F.R.C.S. examination) from Feb. 24th to April 24th, at the Infants Hospital, Vincent-square, S.W. Further information may be had from the secretary of the Fellowship at 1, Wimpole-street, W.1.

Appointments

LANGLEY, G. F., Ch.M. Brist., F.R.C.S. Eng., has been appointed Senior Resident Medical Officer at the East Suffolk and Ipswich Hospital.

MACIVER, DONALD, M.D. Edin., D.P.H., Medical Officer of Health to Walton and Weybridge Urban, and Bagshot Rural, Councils.

Hospital for Epilepsy and Paralysis, Maida Vale.—The following appointments are announced:—

ELKINGTON, J. ST. CLAIR, M.D. Camb., F.R.C.P. Lond., Second Honorary Assistant Physician;

NEVIN, S., M.D. Belf., M.R.C.P. Lond., Third Honorary Assistant Physician; and

MCKISSOCK, WYLIE, M.S. Lond., F.R.C.S. Eng., Honorary Assistant Surgeon.

London County Council Hospital Staff.—The following appointments and transfers are announced: A.M.O. (II.) = Assistant Medical Officer, Grade II:—

DONALD, A. B., M.B. Aberd., A.M.O. (II.), North Western;

LEWIS, J. T. R., M.B., D.P.H., A.M.O. (II.), South Western;

PICTON, W. H. A., B.M. Oxon., A.M.O. (II.), Park;

CAMPBELL, R. M., M.B. Aberd., A.M.O. (II.), Grove;

JAMES, M. F., M.B., A.M.O. (II.), Brook;

GIBSON, M. O., M.B. Glasg., D.P.H., A.M.O. (II.), North Western;

CARDWELL, E., L.R.C.P. Edin., A.M.O. (II.), Southern;

LIDDELL, V. L., M.B., A.M.O. (II.), Western;

BATEMAN, L. L., M.B., A.M.O. (II.), Northern; and

WILSON, E. M. R., M.B., A.M.O. (II.), South Western.

Vacancies

For further information refer to the advertisement columns

- Birmingham City Mental Hospital.*—Jun. Asst. M.O. £350.
Birmingham and Midland Eye Hospital.—Res. Surg. O. £200.
Birmingham, Selly Oak Hospital.—Jun. M.O.'s. Each at rate of £200.
Birmingham, St. Chad's Hospital.—Jun. Res. M.O. At rate of £150.
Birmingham United Hospital.—Bacteriologist and Clin. Pathologist. £500.
Bolingbroke Hospital, Wandsworth Common, S.W.—H.P. At rate of £120.
Charing Cross Hospital, W.C.—Hon. Anaesthetist.
Chichester, Royal West Sussex Hospital.—Jun. H.S. At rate of £125.
Connaught Hospital, Walthamstow, E.—Cas. O. £100.
C Coventry and Warwickshire Hospital.—H.S. to Aural and Ophth. Depts. At rate of £125.
Croydon Mental Hospital, Upper Warringham.—Asst. M.O. £350.
Doncaster Royal Infirmary.—H.S. £175.
Eastbourne, Royal Eye Hospital, Pevensey-road.—H.S. £100.
Glasgow Royal Mental Hospital, Gartravel.—Asst. Physician. £300.
Halifax Hospital for Infectious Diseases.—Res. M.O. £350.
Hampshire County Council.—Asst. County M.O.H., &c. £800.
Hove General Hospital.—Hon. Physio-therapist.
Huddersfield County Borough.—Asst. School M.O. £500.
Hull Royal Infirmary.—Cas. O. At rate of £150.
Ilford Council Maternity Home.—Res. M.O. £350.
Institute of Ray Therapy and Electrotherapy, 152, Camden-road, N.W.—Part-time M.O. At rate of £100.
Isleworth, West Middlesex County Hospital.—Res. Anaesthetist. £400. Also Cas. M.O. £350.
Kettering and District General Hospital.—Second Res. M.O. At rate of £125.
Leeds General Infirmary.—Res. Aural Officer. £149.
Liverpool, David Lewis Northern Hospital.—Cas. O. At rate of £120. Also four H.S.'s and two H.P.'s. Each at rate of £80.
Liverpool, Mill-road Infirmary.—Res. Deputy Med. Supt. £150.
Liverpool, Royal Children's Hospital.—Two Res. Phy.'s and two Res. Surg.'s, for City Branch, Myrtle-street. Also Res. M.O. and Res. Surg. O. for Heswall Branch.
Liverpool Royal Infirmary.—Sen. Cas. O. At rate of £120. Also Jun. Cas. O. and H.S. to Skin Dept. At rate of £60.
London Hospital, E.—Med. 1st Asst. and Reg. £300. Also Asst. in X Ray Dept. £100.
London Jewish Hospital, Stepney Green, E.—Out-patient Asst. £125.
London Skin Hospital, Fitzroy-square, W.—Hon. Asst. Physician.
London University.—Readership in Surgery, £800-£1000.
Manchester, Ancoats Hospital.—Res. Surg. O. £200.
Manchester, Booth Hall Hospital for Children.—Res. Jun. Asst. M.O. £200.
Manchester Royal Infirmary.—Four H.S.'s, H.S. to Aural, Gyn., and Ophth. Depts., H.S. to Neurosurgical Dept., H.S. to Orthopaedic Dept. Also four H.P.'s. All at rate of £50.
Metropolitan Hospital, Kingsland-road, E.—Res. Cas. O. £100.
Newcastle General Hospital.—Two H.S.'s and two H.P.'s. Each at rate of £150.
Newcastle-upon-Tyne, Barrasford Sanatorium.—Res. Med. Asst. £250.
Newcastle-upon-Tyne, Hospital for Sick Children.—Res. Surg. O. £250. Also H.P. and H.S. Each at rate of £100.
Nottingham General Hospital.—H.S. At rate of £150.
Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—Clin. Asst.
Putney Hospital, Lower Common, S.W.—Jun. M.O. At rate of £100.
Queen's Hospital for Children, Hackney-road, E.—Three Anaesthetists. One guinea per attendance.
Rochdale Infirmary and Dispensary.—Sen. H.S. £250.
Royal Masonic Hospital, Raenscourt Park, W.—Surgeon.
St. Bartholomew's Hospital, E.C.—Asst. Physician. Also Asst. Physician and Asst. Director to Medical Professorial Clinic.
St. Mary's Hospital, W.—Cas. H.S. At rate of £100.
South London Hospital for Women, Clapham Common, S.W.—Out-patient M.O. £100.
Stirling District Mental Hospital, Larbert.—Third Asst. M.O. £250.
Stoke-on-Trent, Longton Hospital.—H.S. £160.
Swansea General and Eye Hospital.—Cas. O. At rate of £150-£175. Also H.P. and H.S. Each at rate of £150.
Victoria Hospital for Children, Tile-street, Chelsea, S.W.—Cas. O. At rate of £200. Also H.P. and H.S. Each at rate of £100.
Walsall General Hospital.—H.S. At rate of £150.
Warrington County Borough.—Asst. M.O.H. £450.
Warrington, County Mental Hospital, Winwick.—Asst. M.O. £500.
West End Hospital for Nervous Diseases, Gloucester-gate, N.W.—Res. H.P. £125.
West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Clin. Asst. to Out-patient Clinic.
Willesden Borough.—Anaesthetist. Also Throat, Nose, and Ear Surgeon. Each £2 12s. 6d. per session.
Worksop, Victoria Hospital.—Sen. and Jun. Resident. At rate of £150 and £120 respectively.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Mochrum (Wigtown), Stanley (Perth), and Cheltenham (Gloucester).

NEW YEAR HONOURS

THE list of honours issued on Wednesday contains the names of the following members of the medical profession :—

K.C.V.O.

Louis Francis Roebuck Knuthsen, C.V.O., O.B.E., M.D.
Physician-in-ordinary to the Princess Royal; consulting physician to the London Skin Hospital.

Knights Bachelor

Colonel Charles Isherwood Brierley, C.I.E., M.R.C.S., I.M.S. (retd.)

Lately inspector-general of civil hospitals and jails, North-West Frontier Province.

Hugh Berchmans Devine, M.S.

Vice-president of the Royal Australasian College of Surgeons.

Mangaldas Vijbhucandas Mehta, O.B.E., F.R.C.P.I.
Medical practitioner, Bombay.

David Percival Dalbreck Wilkie, O.B.E., F.R.C.S.
Professor of surgery in the University of Edinburgh.

C.B. (Military)

Major-General F. G. FitzGerald, D.S.O., L.R.C.P.I.
Deputy director of medical services, Eastern Command.

C.M.G.

Rupert Briercliffe, O.B.E., M.R.C.P.
Director of medical services, Ceylon.

Colonel Arthur Murray Cudmore, F.R.C.S.
Surgeon to Adelaide Hospital; consulting surgeon of the Australian Army Medical Corps Reserve.

C.I.E.

Major R. S. Aspinall, F.R.C.S.E., I.M.S.
Civil surgeon, Ajmer-Merwara and chief medical officer, Rajputana.

James Cairns, O.B.E., M.D.
Chief medical officer, North-Western Railway, Punjab.

Lieut.-Colonel W. R. Stewart, F.R.C.S.E., I.M.S.
Surgeon to the Viceroy of India.

C.V.O.

William Gilliatt, F.R.C.S.
Obstetrical and gynaecological surgeon to King's College Hospital, London.

Howell Gwynne-Jones, M.R.C.S.
(Dated Dec. 12th, 1935).

C.B.E.

Lieut.-Colonel A. M. Dick, O.B.E., F.R.C.S., I.M.S.
Professor of ophthalmology in the King Edward Medical College, Lahore.

O.B.E. (Military)

Surgeon-Commander F. G. Hitch, M.B., R.N.

O.B.E. (Civil)

William Kenneth Bigger, M.C., M.R.C.S.
Senior medical officer, Palestine.

Cyril Charles Herbert Cuff, F.R.C.S.E.
Surgical specialist, Cyprus.

Robert William Dodgson, M.R.C.P.
Director of shellfish services, Ministry of Agriculture.

John Griffiths, M.R.C.S., D.P.H.
Medical officer of the Neath rural district council.

John Hutson, M.B.E., M.B.
Of Barbados.

Robert Jamison, F.R.C.S.
Principal medical officer, Swaziland.

William Brownlow Ashe Moore, L.R.C.P.I.
Deputy director of medical services, Hong-Kong.

Mrs. Mary Josephine Were, L.R.C.P.I.
Lady medical officer, Federated Malay States.

M.B.E.

Robert McLean Gibson, F.R.C.S.E.
Of Hong-Kong.

Rai Sahib Achhru Ram.
Civil surgeon, Uganda.

Kaikhusro Sorabji Sethna, L.M. and S.
Health officer of the Delhi municipality.

Miss Janet Welch, M.B.
Medical officer, Church of Scotland Mission Hospital, Blantyre, Nyasaland.

Hon. M.B.E.

Fuad Dajani, M.R.C.S.

Kaisar-i-Hind Medal

Ramkrishna Narayan Parmanand, L.M. and S.
Chief medical officer, Adams Wylie Memorial Hospital, Bombay.

Births, Marriages, and Deaths

BIRTHS

ABDULLAH.—On Dec. 7th, the wife of Dr. A. D. Abdullah, of a son.
FISHER.—On Dec. 24th, at Abingdon, Berks, the wife of Dr. John Fisher, of a son.
KIDD.—On Dec. 27th, the wife of H. A. Kidd, F.R.C.S. Edin., of a daughter.
MULHOLLAND.—On Dec. 22nd, at Whimble, Devon, the wife of H. H. Mulholland, M.B. Belf., of a daughter.
PARKINSON.—On Dec. 24th, the wife of Ellis Parkinson, M.B. Birm., of Wyke Regis, Weymouth, of a son.
STARRIE.—On Dec. 24th, at Devonshire-place, W., the wife of E. T. W. Starkie, M.A., B.Chir., of Creaton Sanatorium, Northants, of a daughter.

MARRIAGES

GREENWAY—STRIDE.—On Dec. 21st, at Eastergate Parish Church, Dr. Geoffrey Hudson Greenway to Peggy, younger daughter of the late Mr. F. Stride of Barnham, Sussex.

DEATHS

ALLEN.—On Dec. 28th, at Oulton Heath, Stone, Maria Shepherd Allen, L.R.C.P. Edin., aged 58.
ARUNDEL.—On Dec. 28th, at Wrecclesham, Farnham, Robert James Arundel, M.D. Dub., Capt., R.A.M.C., ret'd.
BALLARD.—On Dec. 23rd, at Shepherdswell, Dover, Philip Ballard, M.R.C.S. Eng., late of Smarden, Kent, in his 81st year.
COTTON.—On Dec. 23rd, at Sheffield, Robert Hugh Cotton, M.R.C.S. Eng., in his 55th year.
DANIEL.—On Dec. 25th, at Ealing, Robert Napier Daniel, M.R.C.S. Eng., aged 69.
GILES.—On Dec. 26th, at Welwyn, Herts, Arthur E. Giles, M.D. Lond., F.R.C.S. Edin., aged 71.
GORDON-WATSON.—On Dec. 21st, 1935, Alice Geraldine Mary, dearly loved wife of Sir Charles Gordon-Watson, of 82, Harley-street, W.1, after a long and painful illness, most bravely borne.
HEWETT.—On Dec. 27th, at The Wilderness, Hampton Hill, Lieut.-Col. Augustus Hewett, F.R.C.S. Edin. (late R.A.M.C.), aged 82.
HOWELL.—On Dec. 21st, at Middlesbrough, Robert Edward Howell, M.B. Edin., aged 70.
MATTHEWS.—On Dec. 28th, at a Brighton nursing-home, Gladys Matthews, M.R.C.S. Eng., late of the C.M.S., Punjab, India.
PERCIVAL.—On Dec. 22nd, at Shenley, Woking, Archibald Stanley Percival, M.A. Durh., M.A., M.B. Camb.
SINCLAIR.—On Dec. 23rd, at 25, Elvaston-place, S.W.7, James Edward Sinclair, L.R.C.P. Edin., formerly of Queen Anne's-gate, and Wyndham House, Aldeburgh.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ROYAL SANITARY INSTITUTE.—Recent developments in sewage treatment and disposal at the London County Council works will be the subject of a paper to be read by Mr. J. H. Coste, the chief chemist of the Council, at a sessional meeting of this institute (90, Buckingham Palace-road, London, S.W.), to be held on Tuesday, Jan. 14th, at 5.30 p.m.

NOTES, COMMENTS, AND ABSTRACTS

PUBLIC HEALTH IN INDIA *

RETROSPECT AND PROSPECT

BY Major-General Sir JOHN MEGAW, K.C.I.E.,
D.Sc., M.B. R.U.I.

MEDICAL ADVISER TO THE SECRETARY OF STATE FOR INDIA; LATE
DIRECTOR-GENERAL OF THE INDIAN MEDICAL SERVICE

Retrospect

IN ancient times certain ceremonials and customs pointed to the interest taken in hygiene by certain classes of Indians. Eugenics have played an important part in the life of the Brahmins for many centuries. Yet for India as a whole, throughout the ages the one and only health officer has been Nature, whose methods have been excessive reproduction counteracted by disease and famine. Man has added his special checks to population in the form of war and infanticide.

Little is known about the population of India in ancient times. One authority estimates that it was 80 millions in 1850 and 130 millions in 1750, while Sir Frederick Nicholson thinks it was only about 100 millions in 1800. Probably for thousands of years before 1700 the population showed mighty fluctuations between the figures of 30 millions and 100 millions.

Two new factors were introduced by Western influences and the spread of education. (1) The effort to prevent deaths from disease and famine. (2) The increase in production of crops and commodities combined with improved distribution. Under these influences the population increased rapidly and, up to a point, the economic condition of the people improved. Great differences of opinion exist as to whether or not the people are now better off than they were 50 years ago, but the really important matter is their present condition and their future prospects. One basic principle is and will always remain the same: good standards of health and well-being cannot be maintained if the numbers of the people are excessive in comparison with the food-supply.

So far as the controlled populations are concerned splendid results have been achieved by officers of the I.M.S. and R.A.M.C., as can be seen from these figures.

Death-rates

	British troops.	Indian troops.	Prisoners.
1859	69.0	20.0	100.0
1875	20.0	20.0	
1900	13.0	11.0	35.0
1912	4.62	4.4	
1933	2.44	2.39	11.2

In the uncontrolled population similar results have not been possible for obvious reasons. The original policy of the Government of India after control had been taken over by the Crown about 1860 was to avoid imposing any restrictions which might arouse opposition among the people, but instead to popularise modern medicine by opening hospitals and medical schools. By this means combined with the spread of general education it was hoped to create a spirit of goodwill towards preventive medicine. Besides, the total revenues of the Governments of India would have been insufficient to set up a modern public health machinery. Hence attention was concentrated chiefly on vaccination, the provision of water-supplies, and drainage systems.

* An abstract of two lectures given under the auspices of London University at the London School of Hygiene and Tropical Medicine on Dec. 4th and 6th. In a previous lecture some of the basic principles of public health had been discussed.

Medical research has been actively pursued in India and has done excellent work; it was established on an organised basis long before the Medical Research Council was created in England. If preventive medicine had been developed on advanced lines and had achieved complete success, the population of India would probably be 500 millions instead of 370 millions. Where would so many people find adequate food if the present population is already badly nourished?

RESULTS OF A SURVEY

I carried out a survey about four years ago by means of a questionnaire issued to 571 Indian doctors in dispensaries situated in typical agricultural villages throughout India. An analysis of the replies gave the following results. Under 40 per cent. of the people were considered to be well nourished, while over 40 per cent. were regarded as poorly nourished, and 20 per cent. very badly nourished. Few people had suffered from actual hunger during the previous five years but the evidence pointed to serious defects in the quality of the food, especially in the matter of high-grade proteins, fats, and vitamins. The average quantity of milk consumed daily by each person in India was about three and a half ounces. Butter in the form of ghee was taken to the extent of one-third of an ounce daily.

The number of cases of the following diseases at the time of the survey was:—

	Millions.		Millions.
Rickets	2½	Night-blindness ..	3½
Syphilis	5½	Gonorrhœa	7½
Leprosy	½	Tuberculosis of the lung	1½
Other forms of tuberculosis	½	Insanity	½
Congenital mental defects	½	Blindness	2

In the cases of leprosy and blindness the figures are much higher than those shown by the census, but are more likely to be accurate. About 15 per cent. of the school-children had enlarged spleens. The average age at which girls begin to cohabit with their husbands is 14, and the average age of the mothers at the birth of their first child is 16. The maternal mortality-rate works out at about 30 per mille against about 5 per mille in England. Something like ten out of every hundred girl wives are doomed to die in childbirth before they cease to have babies.

These data are not claimed to have statistical accuracy as they are obtained by the process of random sampling and the personal equation enters into the replies but they are claimed to give a true general impression of the real state of affairs in the Indian villages, which of course represent the real India. Whether this rough-and-ready survey is accepted as being reasonably accurate or as being unreliable, it follows that there is an urgent need for a careful investigation of the situation.

OTHER EVIDENCE

The recent official reports show that the birth-rate in India remains constantly high, being about 34 per mille, while the death-rate shows a tendency to decline, being 22 per mille against an average of about 34 between 1901 and 1920. These figures suggest that a very satisfactory degree of improvement is taking place in health conditions, but on the other hand the population is increasing at the rate of 3½ millions yearly in British India alone. It is estimated by Colonel A. J. H. Russell, public health commissioner with the Government of India, that the population of the whole of India, including Burma, will be about 400 millions by 1941. These figures raise the momentous question, will the food-supply be enough to nourish so many people? From the survey which has been described above, it appears that the people must be living very close to the line which separates a bare subsistence from starvation.

Prospect

Prophecy is notoriously unsafe, but a forecast of the future is essential if we are to escape from those disasters which give warning of their approach. Even if the present food-supply were regarded as adequate, provision would have to be made for a 10 per cent. increase during the next ten years. If public health were to bring about a further modest reduction in the death-rate, this increase in the food-supply would have to be about 20 per cent. instead of 10 per cent. It is also reasonable to suppose that an immediate increase of about 20 to 30 per cent. may be found necessary to provide for a proper state of nutrition of the existing population, and to this would be added the recurring increase of about 20 per cent. every ten years to feed the increasing number of mouths. Here is a stupendous task for those who are responsible for the welfare of India. The optimists suggest that the one and only thing needful is to lower the death-rate; they hold that the birth-rate will automatically adjust itself; but in India this is not happening, for, while the death-rate has fallen from about 34 per mille, which was the figure before 1920 to 22 per mille during the years 1932 and 1933, the birth-rate has maintained a steady average of about 34 to 35 during the past few years and shown only a slight decline since the beginning of the present century. Better conditions of life can be secured in India by increasing the production of food and other commodities, by improving the distribution of these, and by diminishing the appalling waste which goes on; but these measures must fail if the increase in the population is more rapid than the increase in the available supply of commodities. If the growth of population continues to occur at the present rate, and the increase in the food-supply is not greatly stimulated, the available surplus must gradually dwindle away till there will be no money to spend on education, medical relief, public health, police, railway travel, commerce, &c., and the country must lapse into barbarism. Nature will then resume her sway and once more there will be a wildly fluctuating balance between population and food-supply. This balance will be struck at a much lower average level, probably at something like half of the present population.

Sceptics will ask: "Do such things happen? Are these not the predictions of scaremongers?" The following two examples are given, one to show what has happened in the past and another to show what is actually happening at present. In Ireland the population increased from one and a quarter millions in 1700 to 4½ millions in 1800, and again to more than 8 millions in 1841 when the people were living in conditions far worse than those of the Indian peasant to-day. Then famine, disease, and emigration caused a ruthless reduction in the numbers of the people, and now only about 4 millions can live in a modest standard of comfort. The present low figure is only retained by extensive celibacy and by greatly delayed marriage; no less than 80 per cent. of the males between 25 and 30 remain unmarried. In the case of Japan, where the population has doubled itself in the past 50 years, and where, despite industrial expansion and strenuous efforts in disease prevention, the death-rate is almost the same as in 1890, whereas it has fallen in England by nearly 50 per cent. during the same period. The infant mortality-rate has risen considerably since 1890 in Japan, while it has fallen in England to a good deal less than half the figure of 1890. A significant point is that the birth-rate in Japan has risen appreciably and is over 30 per mille, whereas in England it has fallen from 31·4 in 1890 to less than half. These figures seem to show that public health actually does fail to achieve success while the population is growing at an excessive rate. If India were able to emulate Japan in the thoroughness of her measures for disease prevention, she could only expect to achieve the same results unless she provided a check to the rapid growth of the population.

WANTED, A PLAN

My aim has been to demonstrate that there is reason for grave anxiety about the present condition of the people of India, and still greater reason for alarm about the future so that a searching inquiry is obviously needed. But some people have no faith in inquiries. They agree that the people of India would resent any suggestion of interference with their customs and religions, and it becomes necessary to convince them that a useful purpose will be served by an investigation such as I have suggested. There can be no doubt as to the practicability of plans for increasing production and for preventing disease, these being two of the limbs of the tripod on which rests the welfare of India; the real doubts are about the third limb, which is the regulation of the population. Contrary to the usual belief, educated Indians are willing and even eager to consider any means of dealing with the evil of over-population. The chief prejudice is encountered among Europeans who wrongly imagine that Indians are antagonistic to any suggestion for reform of their ancient customs. Examples might be given to show the attitude of some western officials and even public health workers who refused to believe that there was any need for intervention or that intervention could serve any useful purpose. On the other hand, many British medical officers and laymen have called attention to the urgency of the situation. The medical research workers, for instance, at their annual conferences in 1923, 1924, 1925, and 1926 unanimously adopted a resolution framed by the writer, in collaboration with the late Major-General Hutchinson, I.M.S., in which the Government of India was appealed to for the appointment of a strong commission, chiefly non-technical, to make a thorough inquiry into the wastage of life and the economic depression.

In the report of the Royal Commission on Agriculture published in 1928 it was pointed out that "it is the duty of Government to investigate basic medical problems and to enunciate and direct sound principles of public health administration," also that "the rural problem should be attacked as a whole and at all points simultaneously." In the concluding chapter these words appear: "the demand for a better life can, in our opinion, be stimulated only by deliberate and concerted effort to improve the general condition of the country side, and we have no hesitation in affirming that the responsibility for initiating the steps required to effect this improvement rests with Government." These weighty words have an added significance as representing the views of the Viceroy Designate. Views of Sir George Newman, Mr. J. H. Hutton, D.Sc., I.C.S., Lieut.-Colonel A. J. H. Russell, Mr. Stanley Baldwin, and Lord Eustace Percy might also be quoted, showing that all these recognised the great urgency of the combined economic, population, and health problem in India.

In his recent presidential address, Sir Gowland Hopkins stressed the need for a comprehensive food policy for England. I cordially agree that a food policy for England is needed. Much more urgent is the need for such a policy in India where it is not merely a question of improving unsatisfactory conditions but of saving the country from a relapse into barbarism. Educated Indian opinion is unanimous in recognising the need for reform: even the educated women are most outspoken in their demand for immediate action to lessen the strain on the bodies and minds of Indian girls who are compelled to endure matrimony at an age when English girls are enjoying a happy childhood.

NATURE OF THE PLAN

Assuming that the proposed committee of inquiry are to find it necessary to prepare a plan, it is suggested that the most effective means of dealing with the situation will be found to consist in education. There are various methods of conveying instruction, but chief reliance will probably be placed

on an India-wide scheme of broadcasting. By this means the whole population, including the women, can be informed of the hard facts of the situation and of the steps which have been taken by other countries to secure comfortable standards of life. In this way they would come to realise the need for a new outlook on life.

There is no need for pessimism, provided that immediate and adequate steps are taken. There are vast possibilities of greatly increasing the production of food and of eliminating waste, such as the maintenance of 25 million useless cattle. The finances of India are in a sound condition, the burden of taxation very light, and the country is free from the anxiety which rests on nations which are highly industrial and therefore dependent on the caprices of world commerce. A concerted national effort such as has been made recently in England would bring prosperity to India, but this would be of short duration unless the people acquire a new outlook on life.

NURSING IN RUSSIA

WE have published from time to time notes on the new Russia from the pens of medical authors. A racy account of the impressions of one of the first party of nurses to pay a professional visit to the Soviet Union, which originally appeared in the *Nursing Times* and has now been reprinted in pamphlet form, records observations from a different angle. The party—all members of the College of Nursing—seem to have used their "nurse's eyes and ears, to note the little significances" to good purpose; for example, they kept a sharp look-out for rickets and impetigo, the total count throughout the trip being only some three or four cases of each. Certain characteristics of Russian nursing emerged: (1) matrons' posts as understood here, with all their responsibilities, are unknown; (2) nurses are divided into two classes, "medical sisters," and "nurses" or orderlies; (3) such refinements as screens and sluice rooms, mops, and scrubbing brushes are not taken as seriously as in this country.

The party visited by appointment the Institute of First Aid, Leningrad, containing 200 beds and specialising in acute abdominal cases. The preliminary interview with the doctors—the matron, if she existed, was not brought forward—revealed that the hospital undertakes research work in acute abdominal cases and compiles mortality and morbidity statistics for general reference. Its findings as to the best time to operate on an acute appendix, for example, are promulgated all over the Union. It is called a "first aid station" because it is open night and day and takes in the accidents and emergencies of the district it serves. It has no out-patient department as such. If a worker in the district falls ill he telephones to the hospital doctor to come and visit him in his home, and if he requires hospital treatment—there is not much home nursing in Russia—he is brought in the ambulance. All workers are made thoroughly aware of the medical facilities in their neighbourhood. As working hours are short in Russia, and hardly any of the doctors or nurses live in, the staff is large. This hospital of 200 beds employed 20 doctors, 30 "medical sisters," and 16 auxiliaries called "nurses." There is no distinguishing uniform. Everybody ties a starchless overall over their outdoor clothes, and a limp white handkerchief over their hair, and everybody wears list slippers (with or without stockings), the slippers often being secured by tape. The medical sisters work six hours a day and the nurses eight. There was at one time a shortage of nurses, but the position is rapidly improving.

The informality in the wards was the subject of comment. The wards in Russian hospitals are small—at most ten-bedded, many two- and four-bedded—and the beds are much lower and closer together than in our hospitals. Visitors are allowed twice in every six days. All the patients have ear-

phones, and all seemed to be reading something. On the stairs between each floor is a sort of letter box in which are collected the patients' personal notes to their friends. These boxes are cleared twice a day; friends call for the notes at the entrance and leave their own replies. They can ring up any time between 10 A.M. and 7 P.M. for news of the patients, and there is one hour in the morning during which they can interview the doctors. The hospital provides nine different diets.

Not only at the Institute of First Aid but at the Lenin Hospital, Leningrad (500 beds, 1000 out-patients, ex-patients only, daily) the visiting nurses were interested by the complete absence of screens, and by the elaborate arrangements for assuring that successive batches of nurses were kept informed of the patients' progress and special needs. As there is a good deal of changing of duty, particulars of really ill patients are written on small squares of frosted glass and slipped in front of a viewing screen on the sister's table. There they are lit up like a series of X ray plates. Changes of treatment are put on cards, a card for each patient, and slipped into the slots of an "album"—just as if they were a collection of picture postcards.

A "wall newspaper" is to be found in every hospital. On it one sees photographs of workers, and also articles of general interest, often of self-criticism. One whole sheet may be devoted to a department which has done poor work, or whose staff have grown slack.

The information sought and gained was not all in one direction. The Russian doctors asked pertinent questions of the British nurses; for instance:—

"We understand that, unlike our nurses, very few of you are married, and we think it so strange. Speaking as doctors we would even go so far as to say that it is a physiological crime. We hope you do not think us rude to say so." "Not at all," we replied amiably. "But we work longer hours than you and have little time for marriage if it has to be combined with hospital work. Quite a lot of our nurses do marry, but they are expected to give up nursing then. Anyway, do tell us if you think we look ill or strained." Well, they had to admit that we did not, but as we left, with a mutual exchange of smiles and bows, the faint murmur of "physiological crime" pursued us to the very gates.

It had previously been ascertained that besides the annual holiday of two or three weeks, "medical sisters" were allowed four months' pregnancy leave, two months before and two after childbirth. Many other interesting differences of custom were observed and are here entertainingly recorded.

HAMLET ANALYSED AGAIN

THAT artists who concern themselves with character study may on occasion be more trustworthy guides to problems of psychology than professional psychologists is a thesis well worth discussing. Inevitably Shakespeare, whose intuition provides a veritable index to human character, must loom large in such an argument. Now that psychology endeavours not merely to dissect but to coördinate character, it cannot afford to ignore one whose words appear to stimulate each succeeding generation to fresh interpretation.

Dr. Brock, in a little book recently published,¹ enumerates the theory first that Hamlet's "overgrowth of some complexion," of which he was well aware, was passion, secondly, that Hamlet constitutes Shakespeare's portrait of himself. The latter is, of course, only arguable in a limited sense. At some time in his life Shakespeare must have actually experienced the pangs that wrung all his great creations. If Hamlet was indeed Shakespeare in one phase of his life, he passed from that particular phase to others in which idealism gave way to cynicism, as in Antony, Coriolanus, and Timon, and

¹ The Dramatic Purpose of Hamlet. By J. H. E. Brock, M.D., B.S., D.P.H., F.R.C.S. Cambridge: W. Heffer and Sons, Ltd. Pp. 48. 2s. 6d.

gradually thereafter became philosophy as illustrated in the last plays.

Did Hamlet know that his passions would be likely to ensnare him? This interpretation certainly has no support from Bradley; the picture of the final prevailing of passion as a resultant of two opposing forces—the meaner wish for revenge and the higher restraint of idealism—is one well in accord with actual experience. When, however, Dr. Brock takes the dying words of Hamlet to be a cry of despair, we must remember that the excellent Horatio evidently did not interpret them thus. As to the ghost, the old saying "De mortuis nil nisi bonum" has lost its mandatory force among modern commentators. Dr. Brock concludes that old Hamlet had probably been an egotistical bore in the flesh, and though Hamlet naturally idealised his father, other eyes may have perceived some excuse for his wretched queen.

THE HOSPITAL ALMONER

"Go and ask the lady almoner about that. She will be able to help you." This remark may be heard over and over again in any out-patient department when apparently insuperable obstacles are raised by the patient to a line of treatment deemed essential. And to the lady almoner they go, poor, harassed and worried, mental anxiety contributing its full weight to physical illness, and so interwoven with it that it is impossible to cope successfully with either alone. The new edition¹ of "The Hospital Almoner" shows the variety of ways in which the lady almoner is able to solve problems which to the uninitiated might appear hopeless, and the agencies, State or voluntary, which can be tapped; while for intending candidates there has been added a new and helpful chapter which contains useful practical details of the course of training, of previous qualifications essential and valuable, and of the scope of their future work. The book is essentially practical, like the almoner's activities, and it has been compiled with sympathetic insight based on knowledge of the psychological as well as the material aspects of the fine social service it describes.

It is of interest to compare with this general survey this year's annual report of the Social Service Department of St. Thomas's Hospital, whose almoner's department is world-famous. It tells the story of the varying aspects of the work at St. Thomas's, from the struggle to get the slums of Lambeth removed, to the difficult task of finding money for the many activities of the department. On the financial side, it is interesting to note that patients' donations make up about 10 per cent. of the hospital income, and that the average cost of maintaining a patient at St. Thomas's is about 13s. per day. Interesting too are the sections on the special departments and on the variety and scope of convalescent work undertaken. The co-operation between the voluntary hospitals and the public authorities is a development which has grown rapidly of recent years. A helpful supplement to the work of both the maternity and the children's department is the "Father's and Mother's" centre, which has an educative value far beyond any centre which caters only for one parent.

HYGIENE IN THE SCHOOL

THE movement for the teaching of hygiene as well as biology in schools has created a demand for elementary text-books which publishers have been alert to satisfy. Dr. Gamlin has written a book² intended for teachers in training, for student health visitors, and as a book of reference for school teachers wishing to bring their knowledge of hygiene up to date. It covers a wider range than would be anticipated from its title. Such subjects as heredity,

ductless glands, the welfare of infants and young children, air, ventilation, sunlight, personal hygiene, food, beverages, alcohol, infection and immunity, infectious diseases, tuberculosis, rheumatism, and chorea are dealt with as well as school hygiene. The exposition is clear, the information accurate, and emphasis is properly placed.

Dr. Lyster's book³ is intended to be used in connexion with the class instruction of junior pupils in hygiene. New features in the second edition include a guide to the pronunciation of scientific terms and a revised section on artificial respiration. The book is written in language appropriate to the age of the pupils for whom it is intended, and is freely and, on the whole, well illustrated. There is little to cavil at in the information which it contains, although the relative stress laid on the various aspects of hygiene will not meet the views of some teachers. The section on ventilation would bear modernisation as regards the effects of bad air on health, and it is doubtful if children's memories should be burdened with ingenious but little used ventilating apparatus described here at some length. Some of the diagrams are old fashioned, especially those relating to the stomach and intestines. On the whole, however, this book is a creditable attempt to deal with the difficult subject of hygiene in a way suitable for young children.

BIRTH CONTROL FOR THE LAYMAN

FROM a prefatory note to yet another little book on birth control it appears that Mr. G. R. Scott⁴ has written it for the lay public, in order to help married couples to solve their own contraceptive problems and select the method or methods best suited to themselves. He has succeeded only in dishing up a somewhat indigestible hotchpotch. Mixed with a certain amount of correct information are not a few practical blunders and a good deal of material which would have been better omitted. The number of methods described, their various possible and impossible combinations, and the lists of contra-indications and indications for their use must surely be confusing and largely unintelligible to laymen. The diagrams are poor and in one place at least inaccurate. It would be interesting to learn whether the author has had any practical experience of selecting and teaching methods of birth control.

REGULATION OF PROSTITUTION

Miss ALISON NEILANS, general secretary of the Association for Moral and Social Hygiene, writes: "In your issue of Dec. 28th, 1935, Dr. C. Rolleston expresses surprise at Dr. White's statement that the examination of prostitutes in regulationist countries is a perfunctory procedure taking one or two minutes. Dr. Rolleston appears to think that nowadays in Paris and the leading French towns these examinations are managed in a different way and much more thoroughly. I have not seen the periodic examination of prostitutes in Paris or in France, but I have seen it carried out by French specialists in Syria, under the French mandate, where the examinations are conducted for the supposed benefit of the French troops. The examination is still performed very much as described in Flexner's book. It takes rather less than one minute per woman examined, and, in addition, at intervals of a few weeks, I believe, a specimen is taken to examine for gonorrhoea. Also in Turkey at the present time the examination only takes from one to two minutes, but I will not comment on that as on the occasion when I saw it

performed it was only for the purpose of taking smears to look for the gonococcus.

"It is always stated that the prostitute in the brothel under medical examination is not usually the source of infection. In so far as that is true it probably is because women liable to periodic examination keep themselves rather cleaner, but they also take a great number of precautions to prevent being discovered in an infectious condition.

"With regard to the letter from 'Traveller' I might point out that the British authorities have completely abolished the regulation of prostitution throughout the whole of our Crown Colonies and dependencies; including Malta and Gibraltar. In Egypt alone this system of tolerated brothels with medical examination of women continues and the results, judging by the figures for the British Army in Egypt, are not altogether satisfactory."

MEDICAL VERSES¹

Mr. Roche has brought together here various verses, the majority of which were written over 15 years ago, many of them having seen light in the *St. Bartholomew's Hospital Journal*, *Round the Fountain*, and the *Busy Bees Magazine*. About one-third of the collection follows the usual type of rhymed skit on medical subjects, though Mr. Roche is both wittier and a better technician than most contributors to hospital journals. The remaining two-thirds contain superior work, and in one or two places display the author as observer and poet. But because some of these metrical exercises are good—note the verses on Chamonix, and the serio-comic obituary note on a blue-bottle—the inclusion of others not so good is regrettable. Some pruning would have raised the standard of the collection, and though great masters of the sonnet have taken liberties in rhyming, it is only they who can take liberties here. The book closes with translations from the Greek and Latin, where several neat renderings of epigrams will be found.

ARTHRALGIA FROM INJECTIONS OF BISMUTH FOR SYPHILIS

A STUDY of the records of the dermato-venereological department of the Rigshospital in Copenhagen has convinced Dr. V. Genner that injections of bismuth not infrequently give rise to more or less troublesome pains in the joints (*Nord. med. tidskr.*, Nov. 2nd, 1935, p. 1753). His study covers the period 1913-32 and concerns 5526 cases of syphilis. Until 1924—i.e., before the bismuth period, and when treatment consisted of injections of mercury and salvarsan—arthralgia as a consequence of anti-syphilitic treatment was unknown. It was only in 1924, the year after the replacement of mercury by bismuth, that such symptoms began to be noticed. Between 1924 and 1932 there were as many as 79 cases of what Genner describes as paratherapeutic ailments of the joints. During the first few years after 1924, the number of cases of arthralgia increased with the raising of the dosage of bismuth; and in the last five or six years, during which the bismuth dosage has been more or less stabilised, there has been a corresponding stability from year to year of the number of cases of arthralgia. As there were 2235 syphilitics treated between 1924 and 1932, these 79 cases represented an incidence-rate of 3.5 per cent.—the same for the two sexes. As a rule, several joints were involved, and the pain was reminiscent of that of rheumatic arthritis. Though it was most exceptional for it to be associated with swelling and redness, the pain could be quite troublesome, and in several cases it persisted for months after the treatment had been discontinued. In two cases its severity necessitated the patients' admission to hospital. In 73 per cent. of all the cases the pain began in the course of the two first series of injections; and the connexion between pain and injection

was often so intimate that the former followed the latter with only a quite short interval. It should be noted that the specific treatment given in the Rigshospital included salvarsan in a goodly proportion of the cases, in association with mercury before 1924, and with bismuth from 1924 to 1932; but it is only in a few cases that Genner gives salvarsan the credit for arthralgia. Indeed, only 4 per cent. of the cases of arthralgia occurred during or after a series of salvarsan injections, whereas 54 per cent. of them occurred during or after a salvarsan-bismuth series, and 42 per cent. of them during or after a bismuth series of injections. In several cases undergoing a combined course of salvarsan and bismuth injections, the arthralgia ceased when the bismuth was discontinued and the salvarsan continued; and relapses followed the resumption of bismuth treatment. Dr. Genner's attitude towards the pathology of bismuth arthralgia is guardedly non-committal.

DIARIES

THE HOSPITAL DIARY in its third year of issue elaborates the useful features with which it started. The quality of materials provided for the daily record is unexceptionable, and the opening section containing tabular information and some signed articles on hospital practice and administration are as useful as the hospital buyers' guide which concludes the volume. The diary, which is edited by Lieut.-Colonel Clement Cobbold, secretary of the Cancer Hospital, London, and Mr. H. F. Shrimpton, house governor of the Children's Hospital, Birmingham, can be obtained from G. R. C. Brook and Co., 27, Old Bond-street, London, W.1, for 5s. 6d.

Warner's CALENDAR OF MEDICAL HISTORY for the use of the medical profession gives a page for each day's record of events, and at the foot of each page is a useful calendar and some interesting item of medical biography or history. Tables of incompatibles, of poisons, of infectious diseases, of glandular secretions, and many others, contain much useful information attractively arranged. The calendar which is printed in the U.S.A. is issued by William R. Warner and Co., Ltd., 300, Gray's Inn-road, London, W.C.1.

THE PREVENTION OF NEUROSIS

Sir Walter Langdon-Brown has distinguished between those ill from unhappiness and those unhappy from illness. A large proportion of patients, even in favourable circumstances, owe their maladies to psychological maladaptation and it is therefore to be expected that in industry neurotics are responsible for much lost efficiency. Statistics have shown that in one factory there may be a sickness-rate of 3 days a year, while in another, where discontent is rife, it rises to 16. This difference seems chiefly to be due to psychological ill-health and, in a paper read before the Society of Medical Officers of Health on Dec. 20th, 1935, Dr. Henry Wilson discussed the causes of neurosis and showed how the methods of preventive medicine could be applied to the problem.

Inborn or physical handicaps, environmental difficulties, or unsatisfactory psychological habits are, he said, the factors which produce absence from work or chronic discontent. The neurotic settles these problems by evasion, but to classify his condition with moral defect is to hamper the psychologist in his already difficult task. Efficient treatment should be preventive in its aims and it is only by finding the cases in childhood that neurosis in the working adult can be excluded. About a tenth of all school-children are seriously backward in mentality, and this has probably a greater bearing upon crime and neurosis than is realised. The neurotic child, though overstrung and shy, tends to have an intelligence superior to his fellows, and he is at once at a disadvantage if his capabilities are either misunderstood or repressed. The attempts to assess the discrepancy between mental age and educational position are in the realm of preventive

¹ Medical and Other Verses. By Alex E. Roche. London: H. K. Lewis and Co., Ltd. 1935. Pp. 92. 3s. 6d.

medicine, for there the individual child can be studied, his needs discovered, and his emotions trained. The psychologist can detect early traits even before their importance is seen by the most intuitive teacher, and these can be treated before they become serious habits of mind.

Circumstances such as physical disease can be improved or the patient's attitude adjusted by satisfactory education and suitable employment. Attempts can be made, especially in the young, to remedy abnormal outlooks and reactions, but often the child's enemies are those in his own household, and the parents are to blame for the bad environment. It is here that the psychiatric social worker becomes indispensable to the clinician in dealing with neurotic manifestations. The object of the medical psychologist is to pick his material and to aid the children to have their values readjusted, not by taboos and social ostracism, but by a real sense of self-control.

Dr. Wilson looks forward to the time when the medical psychologist can apply to early cases what preventive medicine has offered to those physically diseased, when, by means of investigation, early notification, suitable environment, and complete treatment, he can make the misfit an asset instead of a burden to society.

NEW PREPARATIONS

DISSOLVED VACCINES G.L.—Under this name the Glaxo Laboratories Ltd., Greenford, Middlesex, are issuing vaccines "in which the bacterial cells are in solution and the toxic bacterial products are at the same time detoxicated." With ordinary vaccines an antibody response does not develop until antigens have been liberated from the bacterial cell by tissue lysis at the site of inoculation. Dissolved Vaccines, on the other hand, are said to make the antigens immediately available, and their action is therefore more rapid and consistent. Both solution and detoxication are effected by sodium lauryl sulphate which is present in the vaccines at a concentration of not more than 0.025 per cent. Owing to the detoxication, which affects endotoxins and exotoxins equally, the general level of dosage can, it is stated, be considerably higher than that of ordinary vaccines; indeed it is often possible to give a full dose at the first or second injection, no long series of graduated doses being necessary. Good clinical results obtained during the past two years are described in a booklet which may be had on application. The vaccines are put up in rubber-capped bottles in the following varieties: acne and staphylococcus, anti-typhoid-paratyphoid, cold (prophylactic), cold (treatment), influenza, staphylococcus and streptococcus, staphylococcus, streptococcus, whooping-cough (prophylactic), whooping-cough (treatment), gonococcus, and Shiga's dysentery bacillus. Autogenous vaccines can also be prepared.

CLAUDEN is a preparation of lung tissue recommended for the control of hæmorrhage. In the form devised by Fischl in 1916 it is a greyish-brown amorphous powder which can be applied as a local styptic. Besides this powder the Luitpold-Werk, Munich, now prepares a solution in ampoules—for intravenous, subcutaneous, and intramuscular injection, for irrigation of wounds and tooth-sockets, and for instillation into rectum or bladder—and tablets for protracted administration by mouth. All three forms are obtainable in this country from the Medical Laboratories Ltd., 40, Pall Mall, London, S.W. 1. It is claimed that the active principle is not impaired by alimentary digestion, and that after absorption or injection it never causes intravascular coagulation, its action being confined to the point where the blood-vessel is injured. The use of Clauden is advised not only for the prevention and treatment of surgical oozing but also for such conditions as hæmoptysis, nose-bleeding, menorrhagia, and hæmorrhage from the bladder. The makers issue a pamphlet based on over 350 references in medical publications, including

an observation by Knosp (1928) that Clauden reduces coagulation time by about half. Prolonged administration is reported to have overcome the tendency to hæmorrhage in hæmophilia.

ESTOFORM.—The chief constituent of this new antispasmodic remedy is an ester of formic acid, with the formula $\text{HC}(\text{OC}_2\text{H}_5)_3$, which is shown to be non-toxic to animals in doses as high as 5 grammes per kg. of body-weight. Estoform contains 10 per cent. of this ester, together with extracts of *Prunus virginiana* and senega, in a glycerin-spirit base, and doses up to 6 teaspoonfuls were given during clinical trials. The spasm of chronic and acute bronchitis was relieved, patients with miscellaneous coughs were mostly benefited, and definite improvement is said to have been obtained in a large proportion of asthmatics. It should be noted that this preparation contains about as much alcohol as ordinary spirits and requires to be diluted and taken preferably with meals. It is made by the Crookes Laboratories (British Colloids Ltd.), Park Royal, London, N.W.10.

THE OBSTINATE SYRINGE

Dr. C. S. RYLES writes: Having tried, without success, all the usual means for dealing with a valuable glass syringe whose piston was stuck in the barrel, I soaked the syringe in a little "penetrating fluid" such as motorists use for spraying the spring leaves of cars. After a week the piston came out easily. Probably others would be glad to know about this.

ADDRESSES AND ORIGINAL ARTICLES

CARCINOMA OF THE ŒSOPHAGUS
THE QUESTION OF ITS TREATMENT BY
SURGERY*

BY G. GREY TURNER, D.Ch., M.S. Durh.,
 F.R.C.S. Eng., F.A.C.S.

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON AT
 THE BRITISH POSTGRADUATE MEDICAL SCHOOL,
 HAMMERSMITH

"If you have no confidence in success, you can have no hope of winning."—*Lord Lovat.*

In the long history of this lectureship extending over a period of 52 years, no one appears to have thought it worth while to deal with the subject which I have chosen. Probably the reason is because malignant disease of the œsophagus has always been looked upon as so hopeless from every point of view. It is recorded of Dr. William Wood Bradshaw, the founder of the lectureship, that he was a quiet, home-loving, studious man, who diligently cultivated his mind both in literature and science. For many years he practised at Andover and Reading and was for a time vice-president of the Pathological Society in the latter town, so that he was probably very familiar with the sad clinical history of these cases and of the pathological processes which, if unchecked, gnaw steadily at the vitals until death comes to the rescue. The attention which is directed to this subject from time to time is probably the expression of a desire to remove a reproach and to conquer a hitherto unassailable peak. So far the rewards have been few and bestowed infrequently but:—

"Delusion sweet thus tempts us on
 Till all the leaves are like to one
 Yet Hope looks back as heretofore
 And smiling seems to say encore."

J. M. W. Turner.

The majority of physicians and very many surgeons seem to have already decided that, except for palliative measures, surgery cannot claim a place in the treatment of carcinoma of the œsophagus and the earnest student will get nothing but discouragement from text-books. Most authorities still seem to think that it is along other than surgical avenues that legitimate treatment must be directed. As a matter of fact although radium and deep X ray therapy both hold out great promise, no one can claim that at present either method can be expected to do more than palliate these cases, although there are odd instances in which a cure has possibly been attained. At the same time these are no more frequent than the occasional successes as the result of surgical intervention; so that it comes to this, that none of the workers in any field can afford to belittle the efforts of others or can legitimately crow over their own success. In each of the spheres of therapeutic endeavour great ingenuity has been displayed and an enormous effort expended. In this lecture I only propose to tell you something about my own personal experience. It would take far too long even briefly to review the vast amount of work that has been carried out on this subject

and as that has been repeatedly done in the immediate past, I doubt if it would serve any useful purpose.

Some Pathological Considerations

"First things come first."

The prelude to successful treatment must always be an understanding of the pathological features and this is peculiarly so with a secluded structure like the œsophagus, inaccessible and difficult of observation. It has been persistently stated that carcinoma of this organ is of a particularly virulent type that disseminates wide and early, and this teaching has had a depressing effect on the outlook with which the condition has been viewed by the profession. It is only fair to say that those who have paid particular and critical attention to the subject, and especially with a view to the possibilities of direct interference, have from time to time pointed out the fallacy of this commonly accepted dictum. In what one is pleased to call the old days, there was much excuse for this unhappy view of the nature of these œsophageal growths because the observations made in the post-mortem room were nearly always on those subjects who had endured a lingering death from malignant disease of this part without any means having been taken to stay its progress. Anyone who examines the specimens of cancer of the œsophagus in our museums must be depressed by the shockingly advanced condition which they represent. What we really most want to know is the morbid anatomy at a stage at which the question of some form of active treatment arises. We also want exact knowledge of the mode of spread of malignant disease of the œsophagus and the various types which are undoubtedly present together with their most prominent features.

In ten cases in which I removed a portion of the œsophagus for carcinoma, the obvious growth varied in length from 1½ to 3 in. In three instances the tissues beyond the œsophageal wall were invaded and there were obviously infiltrated glands in close proximity. The smaller growths had the appearance of a constricting type as viewed from the outside. All had infiltrated the wall to some extent but none were of the massive or fungating type so commonly seen in museums, and in only one was there proved evidence of distant dissemination—that in the form of secondary deposits in the lung.

In this connexion it is illuminating to review the results of the after-death examinations of a series of patients which I have recently observed at the Hammersmith Hospital.

There were ten who died under observation without any treatment other than palliative gastrostomy. In three there were secondary deposits in the liver or spleen, the total duration of the illness being 14, 16, and 8 months respectively. In one of these cases the growth was situated in the lowest part of the œsophagus and had extensively invaded the cardia and might properly be considered an example of cancer of that part of the stomach which had invaded the œsophagus. In the other seven, the disease had only extended to the surrounding parts or had spread to the glands in the immediate vicinity but without any evidence of distant dissemination.

ROUTE AND RATE OF DISSEMINATION

These findings are entirely in keeping with what I have previously found from the observation of a number of such cases in Newcastle-upon-Tyne. But, of course, there are cases in which distant dissemination does occur and in what is apparently an early stage of the disease, that is to say, as judged from the onset of the symptoms. One may safely conclude that in the œsophagus as in other parts

* Bradshaw lecture delivered before the Royal College of Surgeons of England on Dec. 5th, 1935.

of the body, malignant disease varies in type and in behaviour. The growth may for long remain localised and comparatively slow in its spread, at other times it may involve a considerable part of the wall and rapidly invade surrounding structures, or it may early disseminate both by lymphatic channels and by the blood stream as shown by the occurrence of secondary deposits in distant parts. Very occasionally it may rapidly assume such widespread extension locally and generally as to bring it under the head of general carcinomatosis. In my Bigelow oration I expressed the opinion that probably half the cases remain local until the time of death; in the other half there is spreading to more distant parts. Increasing experience and more detailed attention to this matter lead me to believe that this proportion is probably too high and that one may expect at least two-thirds of the cases to belong to the more limited and locally spreading group. If we exclude from this computation those growths which arise from the so-called abdominal portion of the œsophagus, then the proportion of those that disseminate will be still further and notably reduced. Chevalier Jackson, after an experience of nearly half a century, states of cancer of the œsophagus, "It is not an aggressive type of malignancy; on the contrary, it is a mild, slow and for a long time purely local process."¹

In previous writings I have given clinical illustrations of the general truth of these statements. There must be an early stage at which such growths are limited to a comparatively small area of the œsophageal wall and at which, if there is glandular involvement, it is in the immediate vicinity only. Such a statement suggests the value of the knowledge of the earliest stages of the commencement of the disease. What relation has its early features to the economy of the body and would it be possible at any stage to deal with the condition effectually by some endoscopic method? In order to obtain information on these points I have asked several of my friends who have the opportunity of examining large numbers of patients by the œsophagoscope. They all have to admit that the great majority are fully developed when they come under observation and that the possibility of local radical endoscopic treatment practically never occurs. But many workers are looking out for such opportunities and in the *Proceedings* of the Mayo Clinic for July, 1935, H. J. Moersch tells of a localised carcinoma which he was able to remove by endoscopic diathermy, the patient being alive and free from recurrence six months later. Unless it becomes the routine to examine systematically large numbers of patients endoscopically without waiting for symptoms, it is unlikely that growths in an early stage will be found. It is said (Chevalier Jackson) that normal swallowing can take place when the diameter of the œsophagus is only 5 mm. and that probably the peristaltic wave is not interfered with until the growth becomes annular. This knowledge emphasises the imperative necessity and importance of skilled examination by methods of precision the moment there is any complaint of alteration in the act or comfort of swallowing.

The problem, though so much more difficult, is very similar to the position with regard to the diagnosis of early malignant growths in the rectum. For long I had hoped that the almost routine use of the sigmoidoscope would lead to the discovery of many cases of rectal cancer in which it would be possible

to contemplate an early local resection with conservation of the sphincter. Unfortunately this hope has not so far matured.

Anatomical Considerations

The main facts of the anatomy of the œsophagus are well understood and for the most part adequately dealt with in the more ample books on anatomy. For those who contemplate direct surgical interference I would, however, suggest that the best way to study the relationships of the parts concerned is in transverse sections of the body. In order that the impression may be an accurate one, it is essential that such sections should be life-size, as it is so easy to be misled with regard to depth and distance by reduced pictures of this sort. For the purpose I can strongly recommend the "Atlas of Topographical Anatomy of the Head, Neck, and Trunk" produced by the late Prof. Johnson Symington of Belfast. The true œsophagus itself is really shorter than one imagines and a length of from 9-10 in. is usual. This is about the same as the length of the ureter in situ or the distance from the antecubital fossa to the front of the wrist. It is quite true that the tube may vary to some extent, depending for the most part on the size of the subject, and it may be elongated to a remarkable extent when obstruction is of long standing, but this does not appertain in cases of malignant disease. The normal distance from the teeth to the point where the œsophagus enters the stomach is 16 in. The levels of the various parts of the œsophagus are best stated in relation to the bodies or to the spines of the vertebræ. It is convenient to remember that its commencement is opposite the sixth cervical spine, its lower extremity opposite the ninth dorsal spine, and that the crossing of the left bronchus, which is just below the arch of the aorta, is opposite the fourth dorsal spine. It is important to realise that the œsophagus closely follows the conformity of the spine and when, as so frequently happens in the elderly, there is a considerable kyphosis, the upper part of the œsophagus passes almost directly backwards in the early part of its course. There is also some lateral deviation of the œsophagus so that in the upper part of the thorax it inclines more to the right, whereas in the lower part it definitely abuts to the left. For the exposure of its upper part the right side should therefore be selected while for the lower part the left is more convenient. This refers not only to the transpleural approach but to the approach from the posterior mediastinum. Many surgical writers do not appear to appreciate the fact that, though the whole muscle is extraordinarily *distensible*, it is not *extensible* to any extent and only a very small portion, amounting to not more than 4 cm. (a little less than 2 in.) can be excised if the ends are to be brought together without tension. It must also be realised that the tube is readily friable for the muscular wall tears easily, though the submucous coat is tougher. The mucous membrane is in excess and tends to bulge through any incision in the muscular wall. Possibly these conditions are exaggerated when there has been obstruction with consequent alteration in the œsophageal wall.

RELATION TO THE PLEURA

From a surgical point of view, perhaps the most important relation is that of the pleura. It is not sufficiently realised that this membrane is in contact with practically the whole length of the tube on both sides. On the right the contact is intimate

¹ Arch. of Surg., 1926, xii., 236.

throughout; on the left there is a middle portion in which it is protected from the pleura by the prominence of the aorta, but on this side the lowest part of the sac goes definitely behind the oesophagus and is in jeopardy when this part is attacked surgically. Opposite the bodies of the eighth and ninth dorsal vertebræ the two pleuræ sometimes almost meet behind the oesophagus providing this part with a sort of mesentery. These relations have been very carefully verified by my friend, Mr. James Whillis, and the diagram which he has made for me is very accurate (Fig. 1). This relationship is of great importance, because when we attempt to separate the oesophagus from its bed

FIG. 1.—Anatomical considerations: showing the relation of the pleura to the oesophagus. (Dissection and drawing by Mr. James Whillis.)

bringing about this obliteration by some previous preoperative interference, though it is admittedly difficult to ensure that any known method will safely produce pleural adhesions as desired.

THE "TUNNEL"

The next important point is to recognise that while for the most part the oesophagus lies more or less unattached in its bed of cellular tissue, there are certain definite points at which one must expect a certain amount of anatomical fixation. The first of these is the well-recognised broncho-oesophageal muscle attached to the back of the trachea just at its bifurcation or to the left bronchus. This may also connect to the back of the pericardium. The other and less well-recognised points of fixation are near the dome of the right pleura, the arch of the aorta, the subclavians, and the common carotid arteries. The adhesions to the blood-vessels usually contain branches of the vessels to which they connect. Dr. Vincent Pallares, who is now working with me at the postgraduate school, has verified these matters. Except at these points the oesophagus is not adherent to the very important structures which one finds as its fellows. The bed of cellular tissue in which the oesophagus lies is not so obvious in the developing fœtus, but it gradually becomes very well marked in adult life, although unfortunately it is difficult to demonstrate by any pictorial method. Neverthe-

less anybody who examines the oesophagus in situ must be struck by this very loose connexion and by the way it can be very readily separated from its surroundings. The presence of this cellular tissue practically amounts to a bursa surrounding the tube, providing the freedom which is so necessary for its unimpeded movement, not only in the act of swallowing, but during the movements of the body. The importance of this bursa is well illustrated by those occasional cases in which some part of the tube gets abnormally attached, in inflammatory conditions of the glands for instance, and in consequence a traction diverticulum develops. This oesophageal tunnel can be demonstrated in dissections of the fresh cadaver and its surgical importance is at once realised when it is entered from the diaphragmatic hiatus, for the finger can be readily swept round the oesophagus which at this site is extraordinarily easily separated from the bed in which it lies. I have attempted to demonstrate this bursa by distending the cellular tissue with fluid or with oxygen, and I am able to show an X ray in which the latter method was used in a young subject. When a hollow needle is thrust into the lower part of the tunnel and the oxygen turned on, the latter immediately passes up by the side of the oesophagus and reaches the cellular tissue in the root of the neck, and this happens on both sides of the tube, but it is difficult to distend the cellular tissue in front and behind. The arteries which supply the oesophagus next demand attention. The important point to realise is that there are no large branches that pass directly to the tube, so that there is fortunately for surgical purposes safety in numbers.

The arteries are all subsidiary branches springing from named vessels like the inferior thyroid, the bronchial arteries, the intercostals, and the aorta, and they pursue a course of some length before they reach the oesophagus itself. It is also of some moment that for the most part they pass in a downward direction before finally breaking up on the wall of the tube. The vessels supplying the lower end are in a different category. Here the main artery is undoubtedly the special branch from the left gastric, but there is another from the left inferior phrenic. As can be seen in any well-injected specimen, these numerous vessels eventually break up into a very fine plexus on the oesophageal wall.

BLOOD AND LYMPHATIC SUPPLY

In the early days of my surgical interference with the oesophagus, I came to the conclusion on clinical grounds that the blood-supply of that part, which is about one and a half inches above the diaphragm, was, to say the least, precarious. This and other matters have been verified by the Japanese worker Ohsawa, who has shown by a very interesting series of observations the exact area of the oesophagus which receives its supply from the various vessels. The diagram in his recent publication ("The Surgery of the Oesophagus") illustrates this state of affairs very clearly and defines the dangerous anæmic spot, which is of extreme importance in connexion with some of the operative procedures which have been suggested and carried out.

For surgical purposes then we may take it that the oesophagus from its commencement to just below the bifurcation of the trachea is adequately supplied with blood. Below this point the supply becomes less until at a spot about 1½ to 2 inches above the diaphragm it is very poor, in fact dangerously so, for any surgical interference. The last part of the oesophagus above the diaphragm and the intra-abdominal portion is well supplied from the left gastric and from the left

inferior phrenic. The arrangement of the veins is fortunate from the surgical point of view. When I first began to contemplate direct interference with the œsophagus I was very fearful of the hæmorrhage which I expected would come from the azygos veins, but, as a matter of fact, these great trunks do not receive blood directly from the œsophagus and the intermediary vessels only open into the azygos after considerable interval. There are also large branches, which open into the thyroid veins in the neck and, at the lower end, veins, which join the abdominal coronary system. Of course, there are many variations, and in pathological states the veins may be extremely congested as in œsophageal varix, but this condition is not likely to occur in carcinoma.

The relationship of the vagi is also a matter of importance and concern but, again fortunately for the surgeon, the main trunks are not closely adherent and can be separated without much trouble and, in point of fact, except when infiltrated by growth they seem to look after themselves in a wonderful way when the œsophagus is isolated for any surgical purpose.

The lymphatic arrangements seem to be well understood and in keeping with the usual description, but I would like to stress the fact that some of the lymphatics from the lowest part of the œsophagus drain into the glands along the lesser curvature of the stomach, although drainage in the opposite direction may also occur. There are several lymphatic glands lying directly on the œsophageal wall and lymphatic vessels also drain to the peribronchial lymphatics at the root of the lung. The upper part of the œsophagus drains mainly into the lower deep carotid glands. The supraclavicular lymphatic glands on both sides receive a supply from all parts of the œsophagus.

The development of the œsophagus has some bearing on our surgical outlook. For instance, it is well to realise that in the very active changes during the second month of foetal life it is really pushed backwards into the cavity by the development of the lungs and pleuræ. When, therefore, the œsophagus is removed surgically by withdrawing it up into the neck after mobilisation, it is but retracing the steps which brought it into the secluded position which it normally enjoys.

RESISTANCE TO INFECTION

When anatomists speak of the abdominal portion of the œsophagus they are at considerable difficulty to define its exact demarcation; histology and pathology are probably more helpful than the ordinary landmarks for which they seek. The line of demarcation between the epithelium of the œsophagus and that of the stomach is not a very sharp one, and it is quite common to find a graduation between œsophagus and gastric mucous membrane when the matter is looked at histologically rather than by the naked eye. Pathologically growths in this lowest portion of the œsophagus resemble neoplasms of the stomach in their behaviour, for they not only involve the lymphatic glands in the lesser curvature, but they tend to disseminate, and secondary deposits in the liver are a marked feature. The resistance to organised invasion of the cellular tissue surrounding the œsophagus is a matter of supreme importance when surgical interference is contemplated. It has usually been looked upon as of low resisting power, and clinically it is well recognised that infection of this tissue, known as the clinical entity "acute mediastinitis," is extraordinarily rapid in its develop-

ment, severe in its manifestations, and most lethal in its termination. This matter has concerned me very much indeed in connexion with the surgery of the œsophagus and, because of these known characteristics, I have always feared that acute infection of the cellular tissue would be almost a complete obstacle to surgical interference in this neighbourhood. This known tendency to infection is an excellent reason for so arranging technical procedures that no division of the œsophagus and no suturing, which might possibly be attended with leakage, is made in the midst of the tunnel. In the cases in which I have been able to excise the œsophagus and in which the patient has completely recovered or has lived for a considerable time, I have been struck with the almost entire absence of any evidence of acute infection, which I so much feared. It may be that by removing the œsophagus the cellular tissue is so freely opened up that drainage comes to our aid, but that cannot be the sole explanation because in my most successful case external drainage was not provided and yet the patient recovered so well that in three weeks he was able to leave the hospital apparently quite well.

Problems of Diagnosis

In adults a history of steadily increasing difficulty in swallowing without any previous causative factor, such as an injury from imbibing noxious fluids, is almost pathognomonic of œsophageal neoplasm. In the other causes of obstruction such as pouches or spasm the symptoms are for long intermittent and come on in definite attacks which pass off spontaneously. As a rule the onset of dysphagia due to malignant disease is gradual and takes the form of an increasing difficulty with solid foods. More rarely the onset may be sudden, and those patients are fortunate in whom the blocking of the neoplastic œsophagus by some hastily swallowed bolus of solid food early draws attention to unsuspected narrowing, if indeed this warning is promptly followed by the thorough investigation which it demands. This event is comparable to the patient with the large intestine growth, to which attention is first drawn by some solid body amongst the fæces. The average length of history is usually short and yet in the majority, in fact almost always, we find that the disease is well developed at the time that examination is first made. These considerations suggest that in most cases the disease is already well advanced before any symptoms arise. Chevalier Jackson, who has had the opportunity of observing many cases by repeated œsophagoscopy over long periods of time, has accumulated data from which he concludes that most growths have been present for many months before symptoms arise. He is of opinion that when the growth has reached the stage of complete obstruction the lesion has been present for at least a year and probably longer.² Often the discovery of a well-developed growth with a short history has been so surprising as to stimulate one to make a very searching inquiry as to earlier symptoms, but this very rarely discloses anything which might have led the patient even to suspect that there was something amiss. The plain duty of the profession is to realise that any interference with the act of swallowing in adults usually means that a new growth is present and that being so, as soon as a patient exhibits such symptoms a full investigation should be carried out, rather than those temporising measures which so often delay the

² Southern Surgeon, 1935, iv., 1.

arrival of the patient until the disease has still further advanced, often by months. In a series of my own cases the average time which elapsed between the onset of symptoms and the opportunity for dealing with the matter was no less than 15 weeks.

SIGNIFICANT SYMPTOMS

Once having been discovered, the symptoms do tally with pathology and the variation in the speed of the growth is sometimes very remarkable. Some clue as to the type may be suggested by the symptoms of the patients. Those who harbour rapidly growing neoplasms complain of weakness and loss of general health and appetite, rather than of the extreme local disability as disclosed by dysphagia. Long ago my old teacher, Prof. Rutherford Morison, used to point out that the lack of appetite often meant that there were already secondary deposits and that the patient was not likely to live long. There can be no doubt that the outlook in patients who complain only or mainly of mechanical difficulty is much more hopeful than where general weakness and impaired condition is out of proportion to the inability to take food. Anæmia and rapid loss of weight are ominous symptoms. Persistent cough, or cough made worse whenever the patient takes food, is also a very bad sign and often means that a communication between the respiratory passages is already established. But it is incorrect to assume that such a communication will immediately be followed by some type of septic pneumonia although that is so frequent a sequel. I have recently observed a patient on whom gastrostomy had been performed seven months previously for a malignant growth in the oesophagus. The condition was investigated by an opaque drink, and to our surprise we secured a beautiful bronchogram of the left lung. The presence of the opaque material in the bronchial tree did not appear to give rise to any disturbance whatever, and without any special treatment of any sort this man lived for a further period of eight weeks and then slowly died from a general process of inanition. At the same time, if there is any suggestion of such a communication it is most important that such interference as may be necessary should be conducted under local anæsthesia.

Sometimes there is long-standing history of either persistent difficulty in swallowing or an exacerbation of a degree of difficulty which has existed for many years. I have come across this combination in two striking cases. While this sort of history is usually suggestive of some condition that is non-malignant, it must be borne in mind that some of these patients

do ultimately develop malignant disease and I think that is especially so in women. The comparative frequency of an upper oesophageal spasm in the female sex has often been noted and has been followed by the development of malignant disease in quite a proportion of cases. Prof. Lambert Rogers, who has drawn attention to this association,³ is inclined to think that the treatment he advocates may be in some degree prophylactic against the development of malignant disease.

When a patient is examined as soon as difficulty in swallowing declares itself, it is unlikely that there will be any physical signs that can be discovered by ordinary methods. We must urge the complete examination at this stage by the X ray and the oesophagoscope wherein seems to lie the only hope of discovering the growth at a stage at which treatment has a chance to be effective. But, at whatever stage the patient is seen, it is essential that an ordinary examination should be made in the first instance, if for no other purpose than to eliminate conditions suggestive of dissemination. Such an examination involves the palpation of such part of the oesophagus as can be reached in the root of the neck. Sometimes the growth can actually be felt; it may even then be stony-hard and fixed, or it may be moved from side to side and moves up and down on swallowing. Though the actual growth is rarely felt, there may be some enlargement of the glands which is suggestive, and in this disease the glands at the root of the neck are commonly affected on both sides. In the same way the lower end of the oesophagus is sometimes suspected to be the seat of a growth, when, as a matter of fact, the neoplasm is really in the cardiac end of the stomach. In these circumstances the growth may occasionally be felt in the latter situation and there is no excuse for not making such

an examination as might detect it. For the same reason and in order to eliminate advanced cases examination of the liver and peritoneal cavity for secondary deposits is important.

USE OF X RAYS AND OESOPHAGOSCOPE

The detection of growths in the middle part of the tube by ordinary examination is wellnigh impossible, but it should never be omitted because sometimes the signs point to an extra-oesophageal growth, which will explain all the symptoms. The confirmation of the diagnosis in the absence of physical signs is of course most conveniently made by X ray examination, and this may tell us a great deal more than

FIG. 2.—Large growth in lower oesophagus almost completely separated from its bed as a result of exploration from the abdominal hiatus.

³ Brit. Jour. of Surg., 1935, xxii., 829.

merely the situation and the nature of the obstruction. In fact, if we are to contemplate direct interference, we must ask of it information, not only as to the nature and site, but with regard to the size, the shape, and especially the length of the growth, as well as the question of the condition of the oesophagus above it. It is also by this plan that I think we may get the most valuable help as to the question of fixation of the growth by local infiltration. This may be demonstrated by the absence of the swallowing movements conveyed to the growth and possibly by movement in response to change of position. It has been suggested that the relationship of the neighbouring organs, for instance the aorta and the heart, may similarly give such information.

After the X ray examination, the use of the oesophagoscope is by far the most important method. By its means the presence and nature of a suspected lesion can usually be determined and in doubtful cases a fragment may be removed for histological examination, while the presence of outlying nodules and multiple growths may also be established. I have been a little disappointed at the small amount of other information which this method furnishes; one cannot get much help with regard to the extension of the growth beyond the wall of the oesophagus. If there is any question of the involvement of the lung root, bronchoscopy should certainly be carried out and has occasionally given valuable information. The method of retrograde oesophagoscopy is now on trial and may have possibilities that make it worth while, in spite of the fact that it demands an abdominal operation in itself. Gross extension to other parts and the involvement of nerves, such as the recurrent laryngeal and sympathetic, are an evidence of the utter futility of any but the simplest palliative measures. As yet most patients suffering from oesophageal growths are in a state of serious subnutrition when they come under the notice of the surgeon, and gastrostomy or jejunostomy is imperative. In these circumstances I think it is much better to make the gastrostomy first and to carry out detailed investigation as soon as their condition will allow. Whenever the patient's condition permits the upper abdomen should be explored at the time that the gastrostomy is made. When the growth is at the lower end, any extension to the stomach can be noted and whether or not there are secondary deposits in the liver. The condition of the glands along the lesser curve of the stomach is most important, for when they are infiltrated in oesophageal cases it almost invariably means that the growth is entirely beyond the possibility of direct interference. But having discovered the presence of a growth and eliminated such ordinary signs of dissemination as can be made out on clinical examination, what more can we do in order to determine whether or not there are such hidden extensions of the neoplasm as to render an attempt at its removal inadvisable?

I would like to emphasise the importance of re-examining these patients after such relief as may have been provided by gastrostomy. An extension to the bronchus may be entirely unsuspected one day, while by the next perforation may have occurred and aspiration pneumonia be developing. General well-being as expressed by the patient, appetite and relish for food, and gain in weight are the best indications of improvement. Despite what has been said by the ardent endoscopists about the futility of surgical exploration there are ways in which useful information may be gained without unjustifiable risk.

THREE AVENUES OF EXPLORATION

Growths in the upper third may be explored by exposing the oesophagus in the root of the neck and sounding the oesophageal tunnel with the finger. If the growth is found to have infiltrated the peri-oesophageal tissues or neighbouring structures like the trachea or aortic arch the exploration may be abandoned without the patient coming to any harm. With growths in the lower third the same sort of exploration may be conducted from the abdomen. The left lobe of the liver should be mobilised and the tunnel sounded with the finger introduced through the diaphragmatic hiatus (Fig. 2). For growths in the intervening portion, the transpleural approach is both feasible and practicable and is not necessarily attended with any great risk.

By whatever route the exploration is conducted, it should be the rule that unless the oesophagus with the growth can be easily separated from its bed by the insinuating finger it is best not to attempt removal. I have conducted each of these methods of exploration without any harm coming to the patient. When it has been otherwise the fatality has nearly always resulted from opening up an infected focus outside the growth or actually tearing into the growth itself. In either case a rapid form of infective mediastinitis has carried off the patient. Whenever the surgeon makes such an exploration, he ought to be prepared to carry straight on with the operation of excision if found to be feasible. In some cases a growth of the lower oesophagus has been explored by sounding the tunnel at the time of making the gastrostomy. Having found the conditions favourable for an attempt at removal, I have returned to the problem in three or four weeks' time when the patient's general condition had sufficiently improved to warrant the attempt at excision. To my dismay the growth was by then densely fixed and irremovable, presumably a consequence of the previous traumatism which the exploration had inflicted. So that I am prepared to advise that if the patient is well enough when the gastrostomy is required, the condition of the liver and the glands along the lesser curvature may be investigated, but that any further exploration should be deferred until the patient has obtained the optimum improvement from preliminary measures and the surgeon is prepared directly to follow up exploration by excision should it appear feasible. For my own part I am not depressed by the 12 cases in which exploration has shown that the disease was too far advanced, but am greatly impressed by the fact that in no less than 19 cases it was possible to remove the growth, and in 13 with great promise of success, if technical preparation and achievement had been equal to the opportunity.

(To be concluded)

BRISTOL ROYAL INFIRMARY.—The number of patients received during the year at this hospital again reached a record, the casualty department dealing with 42,000 cases (115 a day). The annual expenditure exceeds the annual income by £30 a day.

HOME FOR RHEUMATIC CHILDREN AT SMETHWICK.—Dr. Clyde McKenzie, chairman of the health committee, announced at a meeting of the Smethwick town council on Jan. 1st that the Ministry of Health had approved the scheme for the provision of a home for rheumatic and marasmic children. The building will accommodate some 30 children, and will adjoin the Firs Open-Air School, which those children will be able to attend.

INTERMITTENT CLAUDICATION AND ITS QUANTITATIVE MEASUREMENT

By H. T. SIMMONS, Ch.M. Manch., F.R.C.S. Eng.

ASSISTANT SURGEON TO THE CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE, MANCHESTER; CHIEF ASSISTANT, MANCHESTER ROYAL INFIRMARY

(From the Department of Surgery, University of Manchester)

INTERMITTENT attacks of limping in horses have been recognised by veterinary surgeons for well over a century and in 1831 Boullay¹ demonstrated that they were associated with an ischæmic condition of the hind limbs. In 1858 Charcot² described a similar condition occurring in a man and introduced the name intermittent claudication. His patient had a traumatic aneurysm of the proximal part of the right common iliac artery, with obliteration of the lumen of the distal portion, and Charcot pointed out the similarities between the intermittent limping of this man and that observed in horses. Erb,³ and the German writers immediately following him, gave excellent descriptions of the claudication and associated symptoms, but wrote as though it constituted a morbid entity, inventing at the same time a number of different descriptive names which only served to confuse the issue. Buerger⁴ vigorously attacked the suggestion that this condition constitutes a disease; he pointed out that intermittent claudication is a very striking symptom of muscular ischæmia due to varying pathological conditions.

A small proportion of cases of intermittent claudication are due to pure spasm of the arteries in neuropathic individuals and no structural disease of the vessels is demonstrable either at the time or in later years. Apart from this relatively rare "functional vasomotor" type, the presence of this symptom is evidence of organic vascular disease which has produced some degree of occlusion in the vessel. Arterio-sclerosis, thrombo-angiitis obliterans, and syphilitic endarteritis are the usual causes of the vascular disease. The symptom of intermittent claudication is, however, most often present and best studied in thrombo-angiitis obliterans.

The patient complains that shortly after beginning to walk he notices paræsthesiæ, tension, and weakness in the calf muscles which become painful. These symptoms steadily increase in severity so that walking is embarrassed and finally becomes impossible. The symptoms fade after a rest of a few minutes and a further period of walking is then possible.

The pain is cramplike and arresting, usually in the calf, but sometimes in the sole of the foot. A few patients

have likened it to "a clod of clay under the foot," and others to a "tight string tied round the calf, just below the knee." The trouble begins earlier if the patient walks rapidly, or uphill, an observation which he quickly makes and allows for in his walking. The muscles of the thigh and buttock may be affected, indicating involvement of the iliac vessels and a graver prognosis.

This typical sequence of embarrassment of muscular action after a short period of work, followed by recovery on resting, occurs in other muscle groups, and the term intermittent claudication is applied to the syndrome when observed in any part of the body, though it is usually restricted to its occurrence in the lower limbs. The arms are occasionally affected in arterio-sclerosis, and in thrombo-angiitis the presence of claudication in the arms is of grave omen because the legs will be found to be extensively involved, if, indeed, they have not already been amputated. Determan⁵ reported the case of a young Russian whose tongue was affected so that after 5-8 minutes, speech became impossible and the motility returned only after a period of rest.

Charcot believed that the pain was due to the ischæmia and resulting anoxia of the muscles and nerves of the limb, but Lewis⁶ with his recent experiments suggests that the muscles elaborate a pain-producing factor (P). This passes out into the tissue spaces and is normally removed by the blood stream. The development of pain is dependent on the accumulation of a certain concentration of this substance in the tissue spaces, and so long as the circulation is adequate pain is avoided. Should the circulation be inadequate, pain is produced when the requisite concentration of P is attained, and disappears only after a period of rest long enough to enable the blood stream to wash away the P factor and lower its concentration below the pain threshold.

A METHOD OF ESTIMATING CIRCULATORY EFFICIENCY IN THE LEGS

The condition is always bilateral in thrombo-angiitis obliterans, but the leg more severely affected always halts the patient, so that he is not aware of the condition of the other leg. It is a peculiar and constant observation that when the second leg does give symptoms, the arterial occlusion progresses much more rapidly than on the side first affected.

It is important, therefore, to estimate the condition of the circulation in both legs, and especially when considering sympathectomy operations for thrombo-angiitis obliterans. The chief anxiety of the surgeon who is called upon to advise for or against sympathectomy in a case of thrombo-angiitis obliterans, lies in the difficulty he has in estimating just how far the circulation of the limb is depreciated.

The apparatus in use.

The rate of appearance of rubor in the dependent and of blanching in the elevated position will afford some guide; the more rapidly these things happen, the worse is the circulation. Such a guide is, however, at best a rough one. The effect of a spinal anæsthetic in raising the surface temperature of the limb is apt to be misleading since a rise of skin temperature bears no necessary relation to the amount of blood which may be entering the muscle bellies. The patient's own account of his symptoms is of small value, vitiated as it is by differences of level and of speed. Prof. E. D. Telford suggested that some simple form of ergometer might supply the information required and in a numerical form. Accordingly the apparatus here illustrated has been erected and used in several cases. It consists of a simple ergometer made out of a single inclined plane foot-splint with a hinged foot-piece.

In our experiments we have used a weight of 5 lb. and governed the rate of the exercise by a metronome working at 60 beats per minute. The foot is fully elevated at one beat and depressed at the next so that the weight is raised 30 times per minute. Difficulty in counting the beats is avoided by timing, and half the time, expressed in seconds, gives the number of elevations of the weight. This is the figure that we have used to express the results. We incline the leg piece at an angle of 20° with the idea of ensuring an adequate venous return so that our estimation is directly concerned with arterial flow. It is necessary to prevent the patient raising the thigh from the splint. Flexion at the knee and the use of the thigh muscles must not be allowed. This is secured by the use of an adjustable arch of Duralumin, so arranged that no constriction falls on the thigh. It is also advantageous to give the patient a loop of bandage to hold on to the apparatus so that he keeps his foot squarely planted against the foot-piece. Reviewing the results we find that a normal man can elevate the weight easily 150 times without discomfort. He then notices a dull ache about the instep and calf which does not progress in severity and which does not prevent him from carrying on for 250 times, or more.

THE TEST IN ACTION

The cases of intermittent claudication studied have been due to thrombo-angiitis obliterans and here the result is quite different. In some cases, shortly after commencing the exercise, a sudden pallor of the foot has been noticed, followed by pain in the instep and lower third of the calf. A rapid increase in the severity of the pain occurs with short, rapid, irregular excursions of the foot, until the movement ceases, the patient stating that the pain prevents continuation of the exercise. The pain is exactly similar to that which he experiences on walking. We have always tested the more affected limb first, unless there has been any contra-indication such as gangrene, or ulceration extending on to the plantar surface. The patient has been surprised to find that testing of his supposedly good leg has produced very little better results than those shown on the side of which he was complaining. A typical case is as follows:—

A blacksmith's striker, 45 years of age, well built and six feet in height, developed phlebitis in the superficial veins of the calf of his left leg during August, 1934. He was confined to bed for a month and, during his convalescence, noticed that cramp-like pains appeared in the calf of his left leg if he walked some fifty yards. After a rest of 5–10 minutes he could resume walking, only to be stopped again by the cramp, after continuing a further fifty yards. For about a year before the attack

of phlebitis he had noticed a similar pain in the left leg, but only following a long walk, or towards the end of a busy day. The right leg never troubled him and he had no rest pain.

He came for examination in January, 1935, and then could only walk about ten yards before the pain appeared in the left calf. Both feet showed a moderate degree of rubor, particularly the left. Raising the legs to 45° caused blanching of both feet in thirty seconds and again the blanching was more severe in the left foot. No pulses were palpable in either leg, but the thighs showed weak popliteal and superficial femoral pulses on either side. On both sides there was present a good, strong common femoral pulse. The blood pressure was 124/85, the Wassermann reaction was negative, and general examination revealed no other abnormality. The result of the claudication test was as follows:—

		Plantar flexions.		Remarks.
Left leg	..	{ 25 ..		Pain commencing.
		{ 37 ..		Unable to continue.
Right leg	..	{ 57 ..		Pain commencing.
		{ 75 ..		Unable to continue.

This case may be taken as one of typical thrombo-angiitis obliterans of moderate severity, likely to give a satisfactory result after lumbar cord ganglionectomy. This satisfactory result was indeed obtained as is shown by the readings given by the claudicometer ten months after operation.

		Plantar flexions.		Remarks.
Leg leg	...	{ 130 ..		Pain commencing.
		{ 150 ..		Continuing, but some difficulty.
Right leg	..	150 ..		No discomfort of any kind.

The method appears capable of expressing as a definite figure what one may call the circulatory value of a limb, and particularly is it valuable in assessing the condition of the leg less affected and of which the patient is not complaining. It is likely, as cases accumulate, that this simple method will afford a means of recording results much more accurately than is now done. It is obvious that terms such as "good," "fair," "improved" depend too much on the personal equation of both patient and surgeon to be of much value as clinical records.

SUMMARY

The symptoms of intermittent claudication are briefly reviewed and a simple ergometric method is described by which the severity of this symptom, and its progress after sympathectomy, can be conveniently estimated.

TRAINING WOMEN FOR CITIZENSHIP OVERSEAS.—Last year the Royal Empire Society held its first experimental course for the training of women in citizenship overseas. The imperial studies committee of the Society and the Empire Citizenship Training Council have now joined to put the scheme on a permanent footing and the next course will begin on May 1st. It will comprise a description of the history, constitution, and races of the Empire, and lectures on household management and social services, and how these may be adapted to conditions overseas. Further information may be had from the secretary at 17, Carlton House Terrace, London, S.W.1.

LUMBOSACRAL STRAIN

BY G. A. G. MITCHELL, M.B., Ch.M. Aberd.

SURGICAL SPECIALIST FOR THE COUNTY OF CAITHNESS

FEW nowadays deny the possibility of such an entity as lumbosacral strain. The pendulum indeed has swung too far in the opposite direction, and the condition is diagnosed too often. Only a greater knowledge of its aetiology and clinical features will enable us to give strain its true significance.

THE CAUSES OF STRAIN

To understand how lumbosacral strain is produced, a knowledge of the anatomy and mechanics of the lower spine is essential. As these have already been described in several papers,^{20 21 26 27 46 55 68} this aspect of the problem will not be considered here.

Acute lumbosacral strain may be caused by a sudden blow forcing the junction into positions beyond the normal limits of its mobility, by an effort to prevent some heavy article from falling, or by a sudden movement of the body in attempting to regain lost balance; the spinal muscles are caught off their guard and the ligaments sustain the full force of the injury. The ligaments and the surrounding muscles are stretched or torn, the synovial membrane and articular cartilages of the lumbosacral interarticular joints are bruised, and the corresponding intervertebral disc suffers. One or other of these structures may be predominantly affected, and all gradations of severity are encountered. Acute strains may also be caused by lifting a heavy weight with the body in a slightly bent position, the stoop accentuating the sacral obliquity and increasing the shearing stress at the lumbosacral junction. Another cause is the failure to provide support for the lumbar spine during an operation under a general or spinal anaesthetic or during a debilitating illness, when muscle relaxation and weakness throw additional strain on the ligaments.

After a heavy fall on the buttocks or feet, complaint is often made of low back pain which is sometimes due to lumbosacral strain, although this diagnosis cannot be confirmed until enough time has elapsed to exclude a possible vertebral crush-fracture. The momentum of the falling body, when suddenly arrested, produces a strong downward thrust at the lumbosacral junction, and the patient will be fortunate if he sustains no more serious injury than a strain. Sometimes the lumbosacral angulation is found to be increased after such falls, and nerve features suggestive of irritation or injury may be discovered. It has been suggested that the increased prominence of the junction causes tension on the fourth or fifth lumbar nerves as they pass downwards in the lumbosacral cord to join the sacral plexus, but it is more probable that they are involved in peri-articular exudate.

Diseases or deformities of the lower extremities interfere with the gait, posture, and body balance, and occasionally give rise to lumbosacral or intervertebral strains. Employment necessitating a continual stooping or semi-stooping posture increases lumbosacral shearing stresses and throws great strain on the back muscles, which become fatigued and leave the ligaments to bear most of the load. Working with one foot higher than the other for a long time is said to be the chief aetiological factor in many cases of strain in surgeons and dentists, but this danger may be averted if the foot is kept in the elevated position only for short periods, or if the feet are elevated alternately. It is doubtful if the wearing of

high-heeled shoes is a common cause of low back strain. The tilt produced is mainly compensated for by extension at the ankle-joints and to a lesser degree at the hips, and there is little evidence that a lumbar lordosis of sufficient degree to cause ligamentous strain is produced; the mechanism of the foot is more liable to suffer than the lower spine. Postural and static derangements produce their evil effects by necessitating the prolonged use of the various spinal articulations in abnormal positions, and, just as an unevenly fitted hinge suffers from excessive friction, so do joints suffer from repeated minor injuries caused by working in unusual or extreme positions.

An increase in the weight of the abdominal contents interferes with the body balance, and throws increased strain on the lower spine, the additional weight pulling the trunk downwards and forwards and displacing the centre of gravity anteriorly. To bring the centre of gravity back to a more normal position, the lumbar spine assumes varying degrees of lordosis, while the back muscles contract more powerfully to sustain the additional weight and to maintain the lumbar lordosis necessary for equilibrium. When the body is erect, these muscles are in a state of postural tonus. Normally this can be maintained almost indefinitely and without voluntary effort, for the muscle-fibres act in relays, and when one set is in action the others are quiescent or recovering. A great increase in the load borne by the back muscles upsets the posturing mechanism by throwing an abnormal strain on the muscles, and the lumbar lordosis present in such cases shortens the muscle-fibres so that their power of contraction is decreased according to the well-known physiological law. Neurasthenia, excessive mental work, and worry have also been blamed for upsetting the delicate proprioceptive reflexes which govern the maintenance of posture. In whatever manner the mechanism is upset, the end-result is the same—a certain amount of voluntary muscular effort becomes necessary, and this, in contradistinction to postural contraction, rapidly leads to muscle exhaustion and relaxation so that the ligaments have to bear more strain than usual. Should the muscles be weak or atonic for any reason, fatigue and strain are even more readily induced.

Goldthwait,^{26 27} who did much pioneer work on the genesis of back strains, distinguished two types of persons who are particularly liable to suffer from low backache.

(1) The visceroptotic, with poor muscular development, a long narrow back, a flexible spine often showing lumbar lordosis, and a sharp lumbosacral angle. This type seems to be specially subject to sacro-iliac strain.

(2) The exact opposite—a heavy individual, with a short thick-set body, limited mobility of the lumbar spine, and a varying degree of lumbar lordosis.

In this second type lateral bending in particular is limited, but all spinal movements are restricted. The vertebral bodies and articular processes are large, the latter having crescentic facets, whereas in the first type the vertebral bodies and articular processes are smaller and the articular facets are flattened. These bony differences explain the variations in the spinal mobility in the two types. Goldthwait's second type is supposed to be specially liable to lumbosacral strain.

SYMPTOMS

The chief symptom in lumbosacral strain is low back pain and the onset may be sudden and acute or chronic and insidious. In acute strains the patient

often volunteers the information that, while he was lifting a heavy weight or making a sudden movement, he felt something snap and immediately experienced pain in the lower back. The pain may be intense and localised at first, but later it becomes less severe and persists in a milder form for a variable period. Movement of the back increases the pain. Deep breathing and expulsive efforts produce the same effect, and Heald²⁹ suggests that this is due to tearing of the quadratus lumborum and its anterior fascial covering near their attachment to the iliolumbar ligament as a result of a sudden contraction in an asymmetrical position. This may occur alone, or in association with lumbosacral articular injury, and is likely to be unilateral. The pain is explained by the fact that the quadratus lumborum muscles contract during expulsive efforts in order to steady the lower ribs, and the diaphragm arises partly from the external arcuate ligaments, which are thickened parts of the anterior fascial coverings of the quadratus lumborum muscles.

Sometimes the pain is completely confined to one side, and radiates along the branches of the great sciatic nerve. The lumbosacral articular structures

The commonest sites of referred pain and of hyperæsthesia in lumbosacral strain.

are supplied by the fourth and fifth lumbar nerves, and the anterior and posterior divisions of the fifth lumbar nerves are in close anatomical relationship to the articulations. Therefore pain may be either of the referred variety due to irritation of the articular nerve-endings, or may be caused by direct compression of the fifth lumbar nerve by periarticular œdema or hæmorrhage; at a later date the same effect may be produced by adhesions, ecchondroses, or osteophytes. The distribution of the pain corresponds with the cutaneous areas supplied by the fourth and fifth lumbar nerves, the fifth nerve areas being more often involved than the fourth. (See Figure.)

Effective treatment quickly relieves the pain but, if it is inadequate, the condition passes into a sub-acute or chronic stage with intractable backache which is aggravated by hard work, trauma, or climatic changes. In chronic cases the pain is more diffuse than in acute cases, and all have varying degrees of disability. Patients with increase or decrease in the normal lumbar curvature often have severe pain in the early stages of their deformity when the ligaments are stretching, but as the deformity becomes more pronounced the pain becomes progressively less, till in advanced cases it may be absent. The patient then describes his condition as a weak back because, although the pain goes, a feeling of weakness persists. Others lose all their symptoms and imagine they are cured. This type of case has been compared to the early and late stages of flat-feet. In the early stages pain is often severe, but as the ligaments stretch further the pain gradually decreases, till in the late stage with complete flattening it may be entirely absent.

The symptoms may be out of all proportion to the injury sustained, especially in middle-aged and elderly persons who already have a pathological condition, such as osteo-arthritis, affecting the lower spine. Until the time of the injury the disease may have been entirely latent, and there may be difficulty in deciding whether the symptoms and signs are due to the osteo-arthritis, or whether the clinical features are due to the combined effects of strain and osteo-arthritis. In many cases, even with the most complete examination, no definite decision can be given. In younger persons a congenital abnormality may account for disproportionately severe symptoms, while in others a functional element may be present. In a few malingering may be suspected, but the consensus of expert opinion appears to be that this is comparatively rare.

SIGNS

The patient may conform to one or other of Goldthwait's types. A pendulous abdomen is a common finding, and distension due to cœsis, cysts, or tumours may be discovered. Owing to the depth of the lesions, swelling and discoloration in the lumbosacral region are rare even in acute cases. Deformities of the lower limbs or spine and faulty posture should be noted. The spine may show a lumbar lordosis, and, in cases with unilateral pain, there is often a slight scoliosis to the unaffected side which relieves pressure on the injured joints and widens the intervertebral canals on the affected side, thus diminishing the possibility of pressure on nerves.

Palpation of the lower spine yields valuable information in all cases. Pressure over the spinous processes of the last lumbar or first sacral vertebra, or in the space between may elicit tenderness, but more commonly deep pressure over the regions of the last lumbar transverse processes is necessary before pain is produced. The tenderness is usually greater on one side and occasionally is completely unilateral. In thin persons, deep abdominal palpation may elicit tenderness over the anterior aspect of the lumbosacral junction. A functional element or malingering should be suspected if the patient is inaccurate in the location of points of tenderness, and if he contradicts himself during the same or subsequent examinations. If one is in doubt, the following manoeuvre is often valuable. The hand is placed on the tender region and the patient is asked to lean backwards. As he does so, the hand exerts increasing pressure and in a genuine case the patient soon recognises this, but a malingerer may be so concerned in retaining his balance that he fails to realise that he is now withstanding considerable pressure on a region which a short time before was sensitive to the slightest touch. This test loses much of its value if a neurasthenic element is present, for in traumatic spinal neurasthenia a paradoxical response to light and deep pressure is well known.

In chronic cases pressure over the various points mentioned may cause discomfort rather than actual pain, and this discomfort is usually greater if the pressure is applied when the patient is stooping. Spasm and tenderness of the lower back muscles are common in acute cases. The former is of a reflex protective nature, while the latter is due partly to muscular hyperalgesia and partly to tearing of muscle and aponeurotic fibres.

Neurological examination may reveal tenderness over the course of the great sciatic nerve, and hyperæsthesia along the antero- and posterolateral

aspects of the leg or ankle, or about the sole of the foot. If it is bilateral, one leg is commonly more affected than the other. Muscle wasting, hypertonicity, or atonicity are slight or absent, and the tendon reflexes are normal; if they are abnormal, it is probable that lumbosacral strain is not the only lesion present. I cannot agree with those writers who claim that the first sacral nerves supply branches to the lumbosacral articulations, and who therefore assume that changes in the tendo-Achillis reflexes, and referred pains in the area of cutaneous distribution of one or both first sacral nerves, are possibilities in uncomplicated lumbosacral strain. Attention might be drawn to another common mistake, that the posterior divisions of the fifth lumbar nerves supply the skin over the lumbosacral region posteriorly, so that referred pain and hyperæsthesia are present in this area in cases of lumbosacral strain. The posterior divisions of the last two lumbar nerves end in the muscles and never reach the skin, and it is muscular hyperalgesia and not cutaneous hyperæsthesia which is present.

An investigation of the lower spinal movements reveals interesting changes, though it is necessary to recollect that the degree of spinal mobility varies greatly even in normal individuals. In acute cases muscle spasm interferes with both flexion and extension, whether the patient is standing, sitting, or lying, and whether the movements are actively or passively produced. Likewise lateral bending of the lower spine is impaired, but it is often freer towards one side than the other. In these cases the symptoms and signs are mainly or completely unilateral, and the freer movement occurs away from the affected side. If the patient is asked to bend in various directions, he usually holds his lower spine immobile and assumes the desired position by movements at other joints. Heald²² states that when one quadratus lumborum muscle is torn the patient, when lying supine, cannot raise both legs simultaneously if the feet are placed six inches apart.

Rectal examination is negative in uncomplicated cases of lumbosacral strain, unless the sacral promontory can be reached, when slight pain may be produced.

RADIOGRAPHIC APPEARANCES

In acute uncomplicated lumbosacral strain radiography shows nothing abnormal, but in chronic cases partial ossification of one or both iliolumbar ligaments is occasionally seen and osteo-arthritis changes are not uncommon. Lateral views show the type of lumbar curve, and, if there is much lordosis, the spinous processes may be seen impinging on each other. Congenital anomalies about the sacrovertebral junction should be looked for and the size of the lumbosacral angle estimated. Since the arrangement of the lumbosacral articular processes is very important, Berry⁶ has devised a special radiological technique to determine the angles at which these processes are set so that any asymmetry can be detected.

DIFFERENTIAL DIAGNOSIS

Fractures or dislocations in the lumbosacral region must be excluded, and, as radiographic evidence of a vertebral compression fracture is often delayed, several examinations may be necessary before a positive opinion can be given. Good lateral radiograms are essential to differentiate between lumbosacral strain and early cases of spondylolisthesis.^{43 45} In a case of suspected strain X rays may reveal other

pathological changes, such as osteo-arthritis, tuberculosis, primary or secondary neoplasms, or gonococcal spondylitis, the symptoms being due to a flare up of the previously quiescent disease. Rarer conditions, such as acute osteomyelitis, "typhoid spine," gummatous osteitis, osteomalacia, osteitis fibrosa, osteitis deformans, and tumours of the cauda equina and meninges are less likely to cause difficulties in differential diagnosis. Low back pain is occasionally the earliest symptom in disseminated sclerosis and tabes dorsalis, and the referred pain in the legs and feet in cases of strain may be mistaken for sciatica, while the hyperalgesia of the lower spinal muscles may be suggestive of fibromyositis, the true underlying lesion being missed. Sometimes lumbosacral strain may simulate diseases of the kidney, appendix, uterus, or other viscera.

Congenital anomalies such as spina bifida occulta, interarticular neural arch defects, sacralisation or lumbarisation, may predispose to strain or cause similar symptoms. Incomplete sacralisation or lumbarisation gives rise to most difficulty in diagnosis and unilateral symptoms and signs in such a case suggest that the congenital abnormality may be the cause of the trouble. Spina bifida occulta may cause characteristic nerve features, but local signs are slight and spinal mobility is scarcely affected. Interarticular arch defects of the fifth lumbar vertebra undoubtedly predispose to strain, and it is impossible to separate the symptoms of the former from the latter.

Finally there is the problem of differentiating lumbosacral from sacro-iliac strain. In a certain proportion of cases, variously estimated, at from 8-33 per cent., a condition of combined pelvic joint strain exists. In the others the history, physical examination, and radiographic findings must be considered in every detail, as the diagnosis can be made only by piecing together scraps of evidence which by themselves would be inconclusive, but which, when taken together, make a complete case incriminating one or other joint.

Exact information should be obtained regarding the onset of symptoms. The occurrence of a snap or "giving-way" sensation is important, and one should discover the exact site of the initial pain and whether it radiated. The attitude of the patient at the onset, and the position of maximum comfort should be ascertained; a patient with sacro-iliac strain is usually most comfortable when lying in bed on his unaffected side; a patient with lumbosacral strain when lying on his back with a support under the lumbar spine. Valuable information is obtained by watching the patient walking, standing, or attempting to climb stairs. The short deliberate steps to avoid any jolt or jar, the tendency to climb stairs like a man with an artificial limb, and the habit of standing with one leg bearing most of the weight and with the other leg slightly flexed at the knee are very characteristic of a sacro-iliac condition, but do not absolutely rule out lumbosacral disease. Great stress cannot be laid on alterations in the spinal curvature, but a lordosis is more common in lumbosacral and a scoliosis in sacro-iliac conditions.

Pain and tenderness confined to the lumbosacral or sacro-iliac regions are of the utmost significance, but the proximity of the two areas, and inaccurate localisation on the part of the patient, may cause errors in diagnosis. Radiating pains or paræsthesia are commoner and more extensive in sacro-iliac cases and are felt along the posterior aspects of the thigh and leg, the outer side of the leg, ankle, and foot,

and the posterior third of the sole of the foot. In lumbosacral derangements posterior thigh pains seldom occur, but the distribution of the leg pains closely resembles that found in sacro-iliac cases. Referred pains confined to the outer border of the foot and the heel are more often secondary to sacro-iliac conditions, but, if they are confined to the toes, anterior part of the sole, and inner half of the foot, they are more often due to lumbosacral disease. Posterior thigh pain, if present alone, usually indicates a sacro-iliac condition, while pain referred entirely below the knee suggests lumbosacral strain. Other causes of radiating pain must be excluded. Wasting of the gluteal, hamstring, or calf muscles, or interference with the tendo-Achillis reflex, are rare in lumbosacral but common in sacro-iliac disease, and in the latter Gratz's bimanual method of examination²⁸ may elicit tenderness about one or other sacro-iliac joint. X rays are not of much diagnostic value in acute cases, but in chronic cases they may show partial ossification of the iliolumbar ligaments or arthritic changes affecting either the sacro-iliac or lumbosacral regions.

Forcible lateral pressure over the iliac crests causes pain in all cases of acute sacro-iliac strain and in many chronic cases, but seldom produces pain in lumbosacral strain. Pressure backwards over the symphysis pubis usually aggravates the pain in sacro-iliac but not in lumbosacral strains. Forced flexion, abduction, and external rotation at one hip-joint separate the innominate bones, cause movement at the sacro-iliac joints, and produce pain in cases of sacro-iliac strain (Smith-Petersen's⁶³ "cross-leg" test.) Hyperextension at the hip-joint rotates the innominate bone on the same side and accentuates the pain of sacro-iliac strain.

In Gaenslen's²³ test, the patient lies supine near one edge of a bed or couch. The leg further away from the edge is acutely flexed at the knee and hip till the thigh touches the abdomen, and the patient then holds the limb firmly in this position with both his arms, thus immobilising the lower spine. The other leg is allowed to hang down over the edge of the bed and it is pressed down till the tension on the ilio-femoral ligament and the muscles attached to the anterior superior and inferior iliac spines causes the innominate bone to rotate on the sacrum. In sacro-iliac strain both local and referred pains are produced, and, by performing the test on both sides, it is possible to tell which joint is affected.

It has been claimed for all these tests that they will differentiate between lumbosacral and sacro-iliac conditions, but this is doubtful. The movements of the innominate bones may irritate a strained iliolumbar ligament or a torn quadratus lumborum muscle, which are occasional complications of lumbosacral strain, and low back pain may be produced in this way. Moreover, in Gaenslen's test, the acute leg flexion straightens out the lumbar spine, and this in itself may cause pain in a case of lumbosacral strain. Thus none of these tests is absolutely diagnostic, though the evidence they supply is very valuable when studied in conjunction with other findings.

The "straight-leg-raising" test is performed with the patient supine.

One hand is placed under the lumbar spine, and with the other hand first one leg and then the other is raised, keeping the knee extended; the hamstrings tighten and exert an ever-increasing pull on the tuber ischii, first causing rotation of the innominate bone on the same side, then tilting the whole pelvis backwards, and finally straightening out the lumbar curve.

Movement is first produced at the sacro-iliac joint on the same side, soon followed by movement on the opposite

side, and finally by movements at the lumbosacral and lumbar joints. Thus in unilateral sacro-iliac strain, the leg on the same side cannot be raised as high as the leg on the opposite side before pain is produced; while, if lumbosacral strain is present alone both legs can be raised higher, because pain is absent until movements occur at the lumbosacral junction. The commencement of movement in the lower spine can be felt by the hand placed under it, and it is easy to tell if pain occurs before or after spinal movements begin. If pain is caused before spinal movements begin it suggests involvement of the sacro-iliac and not the lumbosacral region, although even at this stage movement of the innominate bones might irritate a damaged iliolumbar ligament or quadratus lumborum muscle. Pain coming on after the lumbar spine begins to move is more likely to be due to lumbosacral strain. The exact site of the pain affords valuable additional help in locating the affected joint.

Active and passive spinal and hip movements are examined when the patient is standing, sitting, and lying, and they may be altered in such a characteristic way that they provide valuable diagnostic data. As for the others, the degree of mobility in different people, in the two sexes, and at different ages, is so variable that there is no standard by which one can judge whether the range of spinal and hip movements is diminished. In the erect position, forward bending of the trunk is limited and causes pain in both forms of strain. If the patient sits down, forward bending becomes comparatively free and painless in sacro-iliac strain, but this is not so in lumbosacral cases. A sufferer from sacro-iliac strain stoops by combined flexion of the spine and hips until the hamstrings become taut. The movement is then arrested because of pain in the affected joint and can be continued only by flexing the knee on the affected side to relax the hamstring tension. A patient with lumbosacral strain stoops forward by flexing the hips and knees, and the lower spine is held as rigid as possible. Lateral flexion of the spine is less restricted in sacro-iliac than in lumbosacral strain. Smith-Petersen⁶³ has found that passive flexion of the lumbar spine, produced by the examiner flexing the knees and hips while the patient is in the supine position, is much more likely to cause pain in lumbosacral than in sacro-iliac cases because the pelvis tends to move as a whole, thus eliminating movement at the sacro-iliac joints. All these signs and tests considered individually are inconclusive, but they may fit in with others just as pieces fit into a jig-saw puzzle, until a clear picture is evolved from the scattered fragments.

TREATMENT

During the acute stage rest in bed for 2-6 weeks is essential. In the early stages sedatives may be necessary to relieve the pain, and hot fomentations or cold compresses are soothing. The patient should lie on a firm bed, but soft pillows placed under the knees and the lumbar region often give relief. If the pain persists, the back should be strapped with 3-in. wide adhesive plaster, one layer being applied obliquely and another vertically, from the level of the lower dorsal spine to the trochanters; anteriorly the strapping should not extend further than the lateral abdominal lines. In a severe case the patient should be nursed on a posterior plaster shell.

When the acute symptoms have subsided, local massage should be commenced and physiotherapeutic measures instituted. These aid in the absorption of effusion, relieve discomfort and stiffness, and expedite repair. Ultra-violet radiation, radiant heat, radiotherapy, ionisation, or diathermy may be

employed either alone or in combination, and seldom fail to produce a beneficial effect. Graduated passive and active movements should be commenced in six or seven days, or earlier, and should be continued until full movements are allowed in the sitting or recumbent position by the end of 10-20 days, according to the acuteness of the symptoms. These movements prevent the formation of periarticular adhesions which are so often the cause of persistent pain and disability. Deep-breathing exercises in bed are advocated by one or two writers. In the severer cases the patient should be provided with a plaster jacket, or a properly fitted back brace, when he is allowed up; women prefer strong, specially made corsets. The corsets or back brace should be worn during the day for three months to allow of complete healing of ligaments, but the prolonged use of a brace is necessary only in exceptional cases. A course of remedial exercises to strengthen the back and abdominal muscles and to correct postural defects should be prescribed, and these have been advocated as a prophylactic measure after childbirth. Women should be advised to avoid pregnancy for at least a year after an acute lumbosacral strain.

In chronic strain, rest in bed for a short period at the commencement of treatment is beneficial, and physiotherapeutic measures are as important as in acute strain. The patient's general health should receive attention, constipation is treated, and septic foci are eradicated. Large abdominal neoplasms or cysts are removed, and obese patients or those with pendulous abdomens should be put on a suitable diet and fitted with an abdominal support. A back brace is not always necessary or advisable as it focuses the patient's attention too much on his weak back, but, if the pain and disability are considerable, and especially if the patient's work is arduous, there should be no hesitation in prescribing one. Faulty posture should be corrected, and if it is due to any remediable cause, such as a deformity of a lower limb, this must be treated by operation, or by a suitable orthopaedic appliance. The patient should be warned against heavy lifting and against working in awkward positions for prolonged periods.

Persistent pain and stiffness often point to adhesions interfering with the joint action or pressing on nerves or nerve-endings and no amount of heat, diathermy, or ionisation will affect them. Manipulation to break down the adhesions, followed by careful after-treatment to prevent their recurrence, is the logical remedy. The recognised treatment for persistent stiffness in a knee or shoulder after an injury is manipulation, but the application of similar measures to a stiff spine following trauma has not received the same wide recognition. Riches,⁵⁴ working under Bankart at the Middlesex Hospital, claims that manipulation is successful in 90 per cent. of cases with chronic back strains, and "where there is evidence of definite exciting trauma, success may be anticipated in almost all cases." He adds, however, that the improvement in cases of lumbosacral strain is not always permanent, although the permanency or otherwise of the relief is largely dependent on the efficiency of the after-treatment. The method of spinal manipulation described by Jones and Lovett⁵² in their treatise on "Orthopaedic Surgery" is the best. A general anaesthetic is given, the knees and hips are acutely flexed in order to control the pelvis, an assistant steadies the shoulders, and the pelvis is moved in various directions until complete flexion, extension, lateral flexion, and rotation of the spine are produced. Before manipulation is performed

recent radiograms of the lower spine must be examined to exclude other pathological conditions.

Finally we have to consider the type of case where efficient conservative treatment and even manipulation fail to give relief. This may be due to neurosis or to mechanical imperfections at the lumbosacral junction, such as articular processes arranged in the sagittal plane, interarticular neural arch defects, or an almost horizontal sacrum; in other cases the intractable symptoms are caused by superadded disease, and this must be treated. The patient may be so miserable and disabled that operative treatment becomes a necessity, but this should not be undertaken until conservative treatment has had a fair trial, and gross arthritic or other pathological changes negative operation in the opinion of most surgeons. In selected cases stabilisation of the lumbosacral region by Hibbs', Albee's, and other operations has given good results. A successful fusion operation effectually prevents lumbosacral strain by ankylosing the junction, and by shifting the point of weight transmission to a higher spinal level, which is mechanically more stable and less liable to strain. Chandler¹⁷ has devised a method of "triacral fusion" suitable for cases with combined pelvic joint strains, and Rich's⁵³ operation for stabilising the lower spine is designed for a similar purpose.

TREATMENT OF DYSMENORRHOEA BY ALCOHOL INJECTION

BY ALBERT A. DAVIS, M.D., Ch.M. Vict.,
F.R.C.S. Eng.

IN spite of the research, more or less scientific, of centuries, dysmenorrhœa still remains one of the most important and interesting problems of gynaecological practice. It is responsible for an appalling amount of physical and mental distress, and is economically a most costly disability, both nationally and individually. There is, of course, no doubt that the majority of the milder cases are amenable to medicinal treatment, and that a considerable proportion of the severer type react favourably to cervical dilatation; but there remains a large percentage of the latter who are unrelieved by any procedure short of sympathectomy, and it is for these that the technique described below has been devised.

RATIONALE

The object of the operation is to block the nerve pathway to the uterus at its nearest accessible point. The portion of this pathway which most conveniently lends itself to external intervention is the pelvic plexus of Lee-Frankenhausner, which concentrates most of the uterine nerve-supply in a comparatively small area. I have elsewhere¹ described this plexus in detail, but its relations are so important in the present connexion that it will be useful here to summarise their more salient features.

The plexus is a bilateral quadrilateral sheet of neurofibrous tissue lying on either side and in front of the ampulla of the rectum. It stretches forward to a point just short of the posterolateral border of the uterus immediately above the cervix, inclining in a plane parallel with the lateral pelvic wall at this level. In other words, the plexus lies obliquely upon the posterolateral part of the floor of the pouch of Douglas just above the corresponding vaginal fornix, its deeper portion, consisting mainly of parasympathetic (nervi erigentes) fibres, being contained within the uterosacral folds.

The internal iliac artery and vein lie somewhat behind and below the plexus, but the uterine vessels are fairly closely related to its lateral surface. This apparently alarming relationship is in reality of negligible importance, for the extreme mobility of the artery allows of its being pushed aside by the injecting needle without injury. In addition, actual puncture of the vessel appears to be relatively harmless (see below).

Medially is the lateral aspect of the rectal ampulla, to which the plexus is closely adapted. The ureter crosses its superior border from without inwards, to be related to its medial border for a short distance.

The pelvic plexus is the junction at which almost all the nerves supplying the uterus converge. From above it receives abdominal sympathetic fibres via the solar plexus, presacral nerve, and hypogastric plexuses, and the sacral parasympathetics (nervi erigentes) enter it from behind. The nerves to the uterus are distributed from its anterior border in the form of several strands.

The nerve-fibres in the pelvic plexus are inextricably mixed and interlaced, though it is true that the two main constituents—sympathetic and parasympathetic—lie in separate dissectable planes. This latter fact, however, is of anatomical interest only,

for practically it is impossible to differentiate the various motor and sensory fibres contained, and in any case the thickness of the plexus allows of very little discrimination by the exploring needle.

TECHNIQUE

With the patient in the lithotomy position, and under Evipan anaesthesia, the cervix is seized with vulsella and retracted towards the left. The right fornix is further exposed with the aid of a flat lateral retractor. A long graduated Gasserian needle is then passed horizontally through the vaginal mucosa at the side of the cervix for a distance of 0.5 cm., and the retractor removed. The needle is now passed backwards and outwards for approximately 1.5 cm. at an angle of 45° to both the sagittal and coronal planes, and guided by a finger in the rectum to a point 0.5 cm. from the side of the rectal ampulla. The needle is then withdrawn for 0.5 cm., and 1 c.cm. of 85 per cent. alcohol injected, the needle point being kept slightly but continually moving. The same procedure is then repeated on the other side.

DIFFICULTIES AND DANGERS

Perforation of the rectum with consequent cellular infection is avoided by making the injection 1 cm. away from that organ, as calculated from the internal finger. Injury to the ureter is prevented by adherence to the technique described, which keeps the needle point lateral to it. The uterine artery, if touched, usually slips away from the needle, but constant movement of the latter is a further safeguard.

Hofstetter² has suggested that the injection of a destructive substance like alcohol into the loose pelvic cellular tissue might cause a local aseptic necrosis. I have not encountered this complication, and experience with alcohol injection elsewhere leads one to regard it as only a very remote possibility.

It is unnecessary to use more than 1 c.cm. of alcohol on each side, for only a partial destruction of the plexus is aimed at. It must be remembered that the upper part of the plexus contains the motor nerves to the bladder, which have been shown by Learmonth³ to be indispensable to the proper function of that organ. With the quantity of alcohol suggested, these fibres escape injury, but it is conceivable that larger amounts might damage them, with consequent urinary disorder.

RESULTS

Only 6 cases have been treated over a sufficiently long period to be worth recording, and in 3 of these the success of the method has been vitiated by the fact that a cervical dilatation was performed at the same time. But the ultimate result in all was complete and apparently permanent relief, an effect which appears to indicate the superiority of this operation over the ordinary dilatation, in spite of the small number of cases observed.

The latter procedure, as I have suggested elsewhere,⁴ is really a form of sympathetomy, and owes its effect to the disruption of the sympathetic fibres in the cervix. The amount of this destruction is necessarily variable, depending as it does on the type of cervix, the extent and duration of the dilatation, &c., with the result that it relieves only about 40 per cent. of cases so treated. It therefore seems reasonable to attempt to improve this figure by a less crude and more complete denervation of the whole uterus by alcoholisation of the more centrally placed pelvic plexus, an assumption which is apparently justified in the results recorded.

MODE OF ACTION

The relief of dysmenorrhœa which follows the operation described above may be explained in three ways, viz.:

Interruption of sensory pathways.

“ motor ”

“ irregular ovarian influence.

Interruption of sensory pathways.—The results of sympathetomy suggest, though they do not prove, that the autonomic nervous system is capable of conveying afferent pain-sensory impulses. Normally the contractions of the menstruating uterus are not appreciated by the subject, but when they are exaggerated impulses are transmitted to the sensory cortex, which contains, as Sheehan⁵ has recently shown, the highest central sympathetic representation. It is reasonable, therefore, to suggest the interruption of this sensory pathway as the reason for at least part of the relief following the operation.

Interruption of motor pathways.—It has for a long time been assumed, and Moir⁶ has recently proved, that spasmodic dysmenorrhœa is accompanied by a hypercontraction of the myometrium. The exact mechanism of the pain production is disputed, but the muscle spasm appears to be the main contributory cause. Now almost all the motor nerve-supply to the uterus passes through the pelvic plexus, and it is possible that destruction by alcohol of at least part of this supply might have the effect of abolishing the nerve impulses conveying the impulses to abnormal contraction.

Interruption of irregular ovarian influence.—The work of Blotvogel⁷ and of Kennedy⁸ has shown how completely the pelvic plexus is under the control of the ovarian autocoids; apparently it serves as the vehicle for the transmission of at least part of the ovarian influence on the uterus. Disorder of this influence is probably of primary importance in the causation of spasmodic dysmenorrhœa, and as it acts at least partly through the peripheral autonomic nerves, some of the beneficial effects of intervention on the pelvic plexus may be ascribed to this intervention.

It would appear, therefore, that the relief of pain is the result of interruption of the pathway of three separate and distinct impulses. It is difficult to assess the relative importance of these factors, but it is probable that destruction of the sensory nerves is the predominant one. The reason for this assumption is that unilateral alcoholisation of the parametrium relieves pain on that side only (Blos⁹).

COMMENT

The injection of alcohol for the relief of dysmenorrhœa was first introduced by Blos, of Karlsruhe, in 1929, and has since been practised by him on a good many cases. His technique, however, is quite different from the one advocated above, and consists in the infiltration of the parametrium with 8 c.cm. of 75 per cent. alcohol on each side. This method owes its success to the extensive destruction of the most peripheral uterine nerves, rather than of the pelvic plexus itself, and it seems more reasonable to alcoholise that structure directly in the manner described above. To Blos, however, must be given the credit for the invention of a procedure at once ingenious and practical, and one that is likely to be of permanent therapeutic value.

A modification of Blos's infiltration method has also been used by Young,¹⁰ in the treatment of the syndrome named by him “broad ligament neuritis,”

with excellent results. What is, however, of more importance in the present connexion is the fact that those cases complaining of a coincident dysmenorrhœa were relieved of this symptom by the injection. I have since had the opportunity of demonstrating my technique to Prof. Young, and he agrees that, theoretically at least, it is preferable to Bloss's original method.

WHOOPING-COUGH

VALUE OF A SPECIFIC VACCINE IN TREATMENT

BY NORMAN D. BEGG, M.D. Aberd., D.P.H.

MEDICAL SUPERINTENDENT, BOROUGH INFECTIOUS HOSPITALS, SOUTHEAST-ON-SEA; LATE SENIOR ASSISTANT MEDICAL OFFICER, NORTH-EASTERN HOSPITAL, LONDON COUNTY COUNCIL; AND

MARGARET F. COVENEY, M.B. Sheff., B.Sc.

ASSISTANT MEDICAL OFFICER, NORTH-EASTERN HOSPITAL

FEW therapeutic measures can have given rise to more conflicting reports than the vaccine treatment of whooping-cough. Widely varying doses of whooping-cough bacilli, alone or in combination with other organisms, were used by the early investigators and the results, as might be expected, were equally varied.

In prophylaxis the reported results are excellent and the preventive value of a pertussis vaccine would seem proven. A protective vaccine to have any success must be prepared from the hæmolytic smooth form of the bacillus. Madsen,¹ using a vaccine of this nature, has obtained either protection or attenuation in recent epidemics of whooping-cough on the Faroe Islands. On the other hand, Krueger² believes that mechanical disruption of the bacillary body is necessary in order to avoid possible denaturation. In this way an endo-antigen is obtained and has been successfully used by Munns and Aldrich³ in prophylaxis. It is doubtful whether the results obtained with pertussis antigen are any better than those achieved with the intact bacillus.

Success in prophylaxis has caused a revival of interest and has stimulated further investigations into the value of the newer vaccines or antigens in treatment. Stallings and Nicholls⁴ treated 232 patients in the catarrhal and paroxysmal stage of whooping-cough with undenatured pertussis antigen. Abatement of symptoms appeared to follow, but the experiment was inadequately controlled. It is generally agreed that, if success is to follow vaccine therapy, the initial injections must be given early in the disease, large doses must be injected, and smooth colonies must be used in the preparation of a vaccine. Although such a vaccine has been enthusiastically advocated, the few adequately controlled experiments which have been carried out do not show that it is of any value in the treatment of whooping-cough.

PRESENT INVESTIGATIONS

It should be emphasised that we were not concerned with prevention. An attempt was here made to

assess the value of a pertussis vaccine in the treatment of early cases of whooping-cough. Certain limitations are immediately imposed on such an experiment in hospital practice. It is the general experience that only in severe epidemics are whooping-cough cases admitted to hospital in the early catarrhal stage of the disease. This is probably due to the fact that, during marked prevalence, every cough is regarded with suspicion. In less severe epidemics, on the other hand, suspicion is not aroused until the cough has become paroxysmal or until a whoop develops. During the period of this investigation the epidemic was of moderate severity and, in consequence, early cases were limited to those already in the paroxysmal stage of the disease.

The investigation was conducted along the following lines: (1) Cases of whooping-cough, in the paroxysmal or early whooping stage, numbering 60, were graded according to severity on admission. (2) All the cases received routine treatment such as fresh air and simple drugs when indicated. (3) Half of them received, in addition, a specific pertussis vaccine. (4) In a certain number of cases leucocyte counts were done on admission and in early convalescence.

Classification of severity.—This is admittedly unsatisfactory in whooping-cough. Nevertheless, some classification is necessary for purposes of comparison and the following simple one was used:—

1. Total spasms in 24 hours did not exceed 10. Character of spasms mild—cyanosis never seen.
2. Total spasms in 24 hours exceeded 10 but not 20. Spasms of moderate severity—cyanosis occasionally seen.
3. Total spasms in 24 hours exceeded 20. Severe spasms with cyanosis the rule—convulsions occasionally.

All the cases in this series fell into the first or second group of this classification on admission. No case with a severe respiratory complication such as broncho-pneumonia was included.

Vaccine administration.—The vaccine was prepared from recently cultivated smooth strains of *Hæmophilus pertussis* and put up so that 1 c.c.m. contained 10,000 million organisms. Bacilli used in making the vaccine were of proven virulence on guinea-pig injection, and when used for active immunisation of rabbits could protect them against fatal doses of a virulent culture of the same organism. Alternate cases of similar age and apparent clinical severity were given a routine course of this suspension subcutaneously. A course consisted of 0.2, 0.5, 1, 1.5, 2, and 2.5 c.c.m. at intervals of 2-3 days. It was always possible to complete a course within 14 days of admission.

Reactions after vaccination.—Local reactions consisting of erythema and induration were common but transient. General reactions were rare. Three children had a sharp rise of temperature on the evening of injection, but by the next day the temperature had fallen to normal. A clinical impression was gained that children occasionally experienced an increase in frequency and severity of their spasms during the course of injections. The discussion of the significance of this finding we will leave for the moment.

VALUE OF VACCINE THERAPY

Children of approximately the same age and at the same stage of disease were alternately placed in the vaccine or control series and in this way two groups of cases were obtained. Table I. has been compiled to show the result of this classification. It will be seen in section A of this Table that, as far as age and stage of disease is concerned, the distribution is almost identical. It was hoped that the two

groups would be also identical as far as severity on admission was concerned. Reference to section B of the Table will show that this was not achieved. The distribution is less favourable for the vaccine series as the percentage within the Group 2 classification of severity is greater than that for the controls. This is readily explained by the fact that classification

of the vaccine was a tendency to increase the severity of the spasms and to prolong the whoop beyond the 14-day period during which vaccine was being injected. This effect is in agreement with the clinical impression obtained during this investigation and has been previously recorded by Howell⁵ in an investigation at this hospital. It need not necessarily be interpreted as a result of vaccine per se and might be attributed to a psychological effect. Information on this point could be gained in a future investigation by injecting the control series with small quantities of sterile water.

TABLE I

Showing Percentage Distribution of Cases: (A) according to Age and Stage of Disease: (B) according to Severity on Admission.

—	43.3 100.0	56.7	100.0	40.0 100.0	60.0	100.0	..	100.0	100.0

N = 30

N = 30

was attempted on the actual day of admission, in order that there should be no delay in the administration of vaccine. Early classification of severity in such a variable disease as whooping-cough has obvious disadvantages, and in this case has resulted in a disparity for which allowance must be made in any comparison of results between the two series. Allowance can be made in this way. If it can be assumed that the vaccine-treated cases, distributed according to severity on admission, would experience the same increases in severity after admission as the control series, then the total number of vaccine cases who might be expected to get worse would be 15.23. The actual number was 17 (Table II.). In like manner comparisons can be made between the number of vaccine cases who might be expected to cease whooping at a particular period of the disease and the number who did in fact cease at that period. Reference to Table II. will show that the vaccine cases behaved exactly as might be expected, except in the first four weeks of the disease. Here it is significant to note that approximately five fewer vaccine cases ceased to whoop at the end of two weeks, but that five more than were expected had ceased whooping at the end of four weeks.

It seems reasonable to assume, from the figures given in Table II., that the only demonstrable effect

EFFECT OF VACCINE ON BLOOD COUNT

In conclusion an attempt was made to determine whether the injection of pertussis vaccine had any effect on the leucocyte response in whooping-cough. Of 23 children, who formed the subject of this investigation, 12 had received vaccine and the remaining 11 acted as controls. A leucocyte count was done on admission and repeated 14 days later—i.e., at the usual termination of a vaccine course. It was found that both groups showed leucocytosis and lymphocytosis on admission, but that 14 days later the count had returned to normal irrespective of whether vaccine had been given or not. Thus it was impossible to demonstrate, from these counts, any leucocyte change which could be attributed to the injection of vaccine.

CONCLUSIONS

The position with regard to vaccine treatment, as judged by this investigation, would seem to be clear. The injection in the paroxysmal stage of large doses of a pertussis vaccine prepared in accordance with modern methods and beliefs is shown neither to curtail the duration of the disease nor to ameliorate the symptoms. Indeed the only effect obtained was an undesirable one, although not serious. It is noteworthy that no case in the vaccine or control series was fatal. This, in face of the not inconsiderable mortality which prevailed for the general run of cases in the epidemic, appears to be a potent argument for the early hospitalisation of whooping-cough.

We desire to acknowledge our indebtedness to Dr. R. A. O'Brien, of the Wellcome Research Laboratories, for supplying the vaccine and for information concerning its preparation; and to Dr. E. H. R. Harries, medical superintendent of the North Eastern Hospital, for his cooperation and for his permission to publish this paper.

CLINICAL AND LABORATORY NOTES

A SIMPLE TEST FOR GROSS NITROGEN RETENTION IN THE BLOOD

BY JOHN F. BARRETT, B.Sc.

ASSISTANT IN BIOCHEMISTRY IN THE COURTAULD INSTITUTE,
MIDDLESEX HOSPITAL, LONDON

Andrewes¹ in 1924 described a chemical test on the blood for the diagnosis of uræmia, which aroused considerable interest. Later workers,² assessing the value of this test, concluded that the reaction is found only in uræmia or severe renal inefficiency and stated that the retention of indican does not necessarily run parallel to that of nitrogenous bodies. The following test, which is much simpler to perform, does give results which follow the retention of nitrogenous substances, since a positive reaction is due to an increase in the creatinine fraction of the blood.

Reagent.—Add 25 c.cm. of 10 per cent. potassium iodide to 100 c.cm. of Nessler's reagent.³ Under the conditions of the test, this solution no longer reacts with ammonia or with glucose in the concentration in which it occurs in the blood filtrate.

The test is performed by adding one volume of this reagent to one volume of tungstic acid filtrate from blood. It is considered positive if a definite greyish-white turbidity, resembling milk diluted with water, appear within 45 seconds. The test-tube should be held against a black surface and the temperature of the solutions should be 15–20° C.

Since this test takes two minutes to perform and requires only 1 c.cm. of blood filtrate, it should be a valuable aid to the laboratory analyst. In all positive cases smaller quantities of filtrate should be employed for the determination of urea and non-protein nitrogen, thus preventing ruined analyses due to large quantities of ammonia encountered unexpectedly.

Experiments indicate that the reaction is positive when the creatinine content of the blood is greater than 2.5–3 mg. per 100 c.cm. Blood preserved with formalin cannot be used for this test.

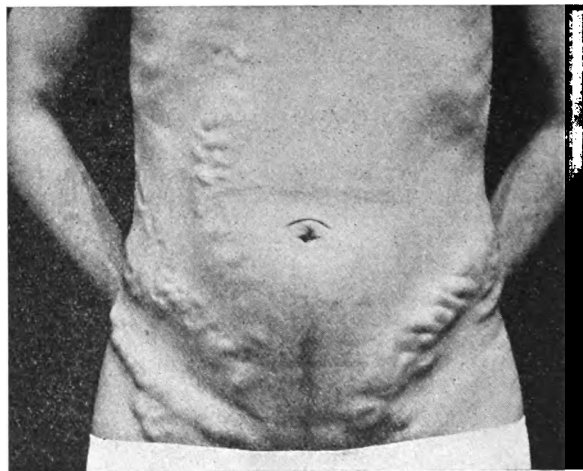

AN UNUSUAL CONTRA-INDICATION TO THE OCCLUSIVE TREATMENT OF VARICOSE VEINS

BY A. L. D'ABREU, M.B. Birm., F.R.C.S. Eng.

SENIOR ASSISTANT IN THE SURGICAL UNIT, THE WELSH NATIONAL
SCHOOL OF MEDICINE, THE ROYAL INFIRMARY, CARDIFF

In examining cases of varicose veins of the leg I have twice encountered a condition which contra-indicated any attempt at obliteration. Both patients hopefully requested a cure by injection, but had such treatment been adopted it might well have led to disaster for both were suffering from thrombosis of the inferior vena cava. The diagnosis can be made by a glance at the abdomen. The usual practice is to examine the saphenous openings before instituting injection treatment, and the purpose of this note is to recommend that the abdomen also should be scrutinised. Neither of the patients informed me of the condition of the abdominal veins.

The accompanying photograph of one of them shows the enormously dilated, tortuous veins coursing upwards from the saphenous openings to communicate through the superficial circumflex iliac venous system with the lateral thoracic vein, which drains into the axillary vein; on the right side the superficial epigastric vein is dilated and anastomoses with the veins of the thoracic wall. The veins in both the lower limbs were enormously dilated and varicose. A similar picture was presented by the other case. Both patients were middle-aged men and in good health and on further questioning both admitted that the venous enlargements had been present for many years, though strangely enough neither could state accurately the date of onset of the condition; one had been in the tropics for many years and had suffered from "tropical diseases." The commonest causes of thrombosis of the inferior vena cava are infections, especially typhoid fever and puerperal

Abdomen of one of the patients.

sepsis, trauma, or malignant disease of the kidney, suprarenal glands or liver (Pleasants,¹ Kerr²), but neither the history nor the clinical examination of my patients disclosed any such cause of their condition. That they had survived for many years the occlusive effects of inferior vena cava thrombosis with no disability worse than that of severe varicose veins is not exceptional, for Parkes Weber,³ Shattock,⁴ and Kerr² have all reported their experience of cases with long survival and few symptoms.

The appearance in the case illustrated is characteristic of thrombosis of the inferior vena cava; Robinson⁵ has recently published a similar picture. My object here is not to inquire into the pathology and clinical features of this disease, at least 318 cases of which have been recorded, but to indicate the value of looking at the abdomen before embarking on the injection of massive varicose veins of the legs. Sclerosis of such veins by injection must hamper unjustifiably the adequate collateral venous circulation that has been established.

A VASOVAGAL ATTACK

By T. E. GUMPERT, M.B. Sheff., M.R.C.P. Lond.
MEDICAL REGISTRAR AND PHYSIOLOGIST, ROYAL HOSPITAL,
SHEFFIELD

Fainting is a common occurrence and usually excites but little comment. Some years ago Lewis^{1,2} drew attention to the slowing of the pulse and the lowering of the blood pressure observed during an ordinary attack of fainting. More recently he³ again stressed these features under the heading of vasovagal attacks and pointed out that most faints in the absence of postural causes and heart-block are in fact vasovagal in origin. The slowing of the heart is due to increased vagal tone and is relieved by the injection of atropine,³ but the lowered blood pressure is an independent phenomenon and presumably due to dilatation of the splanchnic vessels. The combination of these two factors is sufficient to rob the brain of an adequate supply of blood with the result that consciousness is either completely or partially lost.

The other day I had the good fortune to take an electrocardiogram of a patient during a fainting attack.

He was a man of 46 and was known to have suffered from oedema and ascites a few months before I saw him at the out-patient department at the Royal Hospital, but there was no reason to suspect that he had heart-block. (In this connexion it is interesting to note that Lewis³ considers the commonest cause of fainting in cardiac subjects to be the ordinary vasovagal attack and not heart-block.) I had just removed a few cubic centimetres of blood from a vein at the elbow for a sedimentation test. At the sight of the blood in the syringe he became pale and sweated, but did not actually lose consciousness. A few minutes later whilst sitting in the electrocardiograph chair he fainted. The pulse at the wrist was impalpable. With a nurse supporting him I was able to obtain an electrocardiographic record of the vasovagal attack.

Lead I. (Fig. 1) was taken just before he fainted; it shows normal sino-auricular rhythm at a rate of about 70 per minute. The T-wave is inverted. Leads II. and III. (Fig. 1) were taken during the attack. It will be seen that the rate is considerably slowed. In lead II. (Fig. 1) the rate is 42 per minute, no P-wave can be made out, and the R-T interval is prolonged. In lead III. (Fig. 1), whilst he was slowly regaining consciousness, the rate has risen to 52, the P-wave has reappeared but is inverted, and the P-R interval is shortened.

The second electrocardiogram (Fig. 2) was taken within five minutes of the first. By this time he had completely recovered. The heart-rate is 71, 68, and 68 respectively in the three leads, there is no longer any inversion of the P-waves, and the P-R (and R-T) intervals are the same as before the attack.

No blood-pressure readings were taken, but it was noted that the pulse had disappeared at the wrist during the time he was unconscious. The striking features in the electrocardiogram are the disappearance of the P-waves during the unconscious stage and its reappearance, inverted, whilst he was coming round. It would appear that the sino-auricular node was temporarily in abeyance and that the auriculo-ventricular node had taken over its function. Since

the P-wave is completely lost it must be buried in the ventricular complex, and for this to occur the impulse must have arisen low down (anatomically) in the A.V. node at such a point that the auricles and ventricles are stimulated simultaneously (the auricle by retrograde spread from the A.V. node). Presumably with the increase of vagal tone the S.A. node has been thrown out of action and the A.V. node, which is known to possess less inherent excitability, has taken over its function as pacemaker. Equally interesting is lead III. (Fig. 1) in which the rate has risen to 52 per minute and an inverted P-wave makes its appearance. The P-R interval is also a little shorter than in lead I. before the attack had begun. Evidently the impulse is still arising in the A.V. node, but at a higher level such that the auricles are stimulated to contract before the ventricles. The inversion of the P-waves indicates that the spread in the auricle is still retrograde. The second electrocardiogram (Fig. 2), which was taken after recovery, resembles lead I. of the first and denotes complete restoration of sino-auricular rhythm, the level of impulse formation having shifted from the upper level of the A.V. node to the sino-auricular node itself.

CONCLUSIONS

(1) An electrocardiographic record of a vasovagal attack is shown. (2) The slowing of the heart is due to the auriculo-ventricular node having taken over the function of the sino-auricular node as pacemaker. Separate leads show the impulse arising at different levels in the auriculo-ventricular node. (3) On recovery sino-auricular rhythm with its enhanced rate is restored.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY

At a meeting of this section on Jan. 1st, Mr. W. SAMPSON HANDLEY, the president, being in the chair, Mr. G. H. STEELE read a short paper and showed a film on

Retrograde Œsophagoscopy

The results of treatment of cancer of the œsophagus were, he said, highly unsatisfactory. Only a few cases could be operated on, because of the age of the patient and the wide spread of the growth, and the operative mortality was enormous. Irradiation treatment could be described as hopeful but no more. The ideal technique seemed to be deep X rays, and some remarkable cases had been recorded, but this seemed to make the patient very ill and sometimes caused fibrosis of the lungs, while the relief granted was only temporary. The application of radium transpleurally had a very high mortality and poor results, while large doses in the lumen were unsatisfactory. The operations of intubation and gastrostomy were purely palliative. Better results were obtainable from insertion of radon seeds through the œsophagoscope. This did not upset the patient and caused no appreciable mortality. In many cases it produced definite healing of the visible upper end of the growth with relief of dysphagia for a period varying from six months to three years. If the lower end were approached from below almost the whole length of the œsophagus became accessible. Both ends of the growth could be irradiated, but the extra-œsophageal spread would have to be dealt with by X rays. The operation, which was shown in the film, was performed with a Jobson's introducer, the œsophagoscope being passed by direct vision. Cures were not claimed, only a great increase of comfort. Of four cases treated from both ends, one had died six weeks later from innominate artery hæmoptysis. At post-mortem the growth was healed in the œsophagus but had extended to the artery. The second patient had lived perfectly comfortably for nine months and then had died of aortic hæmatemesis. In a third case the two operations had been performed simultaneously—perhaps a mistake—and the patient had died of mediastinitis five days later. The fourth was alive and well after six months and having deep X rays for the extra-œsophageal extensions.

Prof. J. PATERSON ROSS said that the technique at St. Bart.'s had been modified to obviate fibrosis of the lung, and asked Mr. Steele how he estimated the depth of the growth. Dealing with it from both ends was a great advance.—Mr. STEELE replied that radiographs taken in the recumbent position gave a fair idea of the extent of the growth. He had not attempted irradiation during the operation.

Mr. T. B. JOBSON complimented Mr. Steele on the advance he had made. Chevalier Jackson had told him he had never had a cure. If only a case could be treated early enough, there was no reason why cure should not be obtained by Mr. Steele's method. The film showed that the radon seeds introduced from below overlapped those introduced from above.

The PRESIDENT commented on the advantage of intra-tumoral methods and thought that a combination of these with deep X rays would be better than the latter alone. The present method also facilitated

gastrostomy, if this were necessary. If the patient refused radiation, pancreatic ferment with sodium bicarbonate by the mouth might give relief in many cases, healing the ulcerated surface and restoring the power of swallowing.

Dr. H. L. MARRIOTT read a paper by himself and Dr. A. KEKWICK on

Continuous Drip Blood Transfusion

The average in 87 cases, he said, was 5 pints and 29 hours, the largest figures being 11 pints and 62 hours. Present conceptions in regard to dose needed revision; a pint was woefully inadequate for an anæmic patient, especially if he were bleeding. The principle should be made one of quantitative measurement and the restoration of a normal hæmoglobin percentage. Hæmoglobin estimations should check the transfusion. Clinical results were commensurate. The necessity for slower administration followed from these large doses. There was, however, more in administration than met the eye. A. E. Boycott and C. L. Oakley, working with rabbits, had shown that large transfusions did not affect the plasma volume; the added plasma was extruded and the added cells retained. This process went on during the transfusion if given slowly enough. The best rate was to try to increase the patient's hæmoglobin by 10 per cent. every four hours—i.e., in the non-bleeding patient, a pint in four hours, or 40 drops a minute. In bleeding patients the rate must be governed by hæmoglobin estimations. If the patients were weak there should be three stages at intervals of a few days. The apparatus had been described fully in THE LANCET (1935, i., 977, and ii., 78). The blood was kept stirred by bubbling through it a slow stream of filtered oxygen. It was important to bleed donors by a closed method, to avoid droplet infection from the operator. On an average four or five donors were used for each transfusion. The great majority had been friends and relatives, as it did not seem right to deplete the Red Cross service for large transfusions. The approach to the relatives was important; the onus of finding ten or twelve donors must be put on them and no responsibility should be taken by the surgeon.

This method had proved extraordinarily effective. Most of the patients had had bleeding peptic ulcers or had needed transfusion before or after operation. Results had been very satisfactory and in some cases remarkable. In peptic ulcer the blood could be run in as it was lost; 18 out of 22 serious cases had lived and at least half of them could not have lived without the massive transfusion. Three of the deaths had been due to pneumonia and one to perforation. Eight cases of aplastic anæmia had been treated, but it was better to transfuse them once a week and not give the blood by the continuous method. Four transfusions had been done during operation, the blood being run in as the patient lost it and the hæmorrhagic element of shock eliminated altogether.

Mr. V. H. RIDDELL demonstrated by slides and a film a technique with an electrically-driven pump and pointed out its advantages and disadvantages. The latter were financial and mechanical. The apparatus cost 60 guineas, was manufactured abroad, and removed all the romance from blood transfusion. It was, however, simple and reliable and there was only a single rubber tube to sterilise. Less tubing was needed than in Dr. Marriott's apparatus, so that

obstruction due to clotting was less frequent. The rate of flow was absolutely constant and could be regulated. The blood could be introduced at body temperature, its container being surrounded by a bowl of water at 108° F. or a thermostat. The transfusion gave itself. The motor was supplied with a gear system and a reverse, and a revolving cam pressed the rubber tubing against the sides of the metal cup in which it rotated. The tubing was first filled with 3.8 per cent. citrate.

Mr. A. H. BURGESS asked whether this country could not do something similar to what was being done in Russia, where large quantities of blood were collected from the vessels of the newly dead. Accidental, suicidal, and cardiac deaths were used for this purpose.

Mr. ZACHARY COPE asked whether citrated blood was as good as other forms, and if there had ever been rigors in long-continued transfusions.

Mr. ROGERS asked what rate was used for children and how blockage was dealt with.

The PRESIDENT said that surgeons could be divided into ritualists and evangelicals; some liked elaborate methods while others sought simplicity. Blood transfusion seemed to be no exception.

Dr. MARRIOTT replied that the point of their work was dose and rate, not apparatus. A pump had advantages only in children; it was difficult to keep a rate of about 5 drops a minute steady by gravity, and the pump was therefore better. Gravity drip must be watched by a nurse, as it might block and cause reflux. The cooling effect in large transfusions was negligible and it was not worth while to warm the blood, with the risk of cooking it. Citrated blood was better than other kinds as the citrate had a hæmostatic effect in the body. Rigors were due to dead bacteria in the saline or citrate, and could be obviated. In the last thousand cases of drip saline at the Middlesex there had been 16 rigors, and ten of the patients had had them before. Stale blood clot in the tubing might also cause rigor, and fresh tubing should be used for every patient.

Mr. C. JENNINGS MARSHALL read a paper on the treatment of

Diverticulitis of the Colon

The condition was, he said, a newcomer to the pathological consciousness, but was nowadays frequently diagnosed clinically. Patients complained of left iliac fossa pain, and an acute attack often started while straining at stool. Local pain, backache, and slight pyrexia characterised chronic cases. The elongated swelling contrasted with the restricted tumour of cancer, which was afebrile and without backache. Gross obstruction was, in his experience, rare in diverticulitis. Radiographically there was a saw-tooth appearance with distortion and rigidity, but the appearance was suggestive only. The causative diverticulum was never seen, because it was obstructed and did not admit the opaque fluid. Stereoscopic radiography was particularly useful in determining relationships and operability. A perforating carcinoma might not infrequently have arisen in a diverticulum. Chronic cases needed very full investigation. The presence of blood and mucus in the fæces favoured cancer but did not prove it.

Acute cases were associated either with abscess or with perforation. Abscesses might be found in the loin or mesosigmoid. The abscess should simply be drained and the condition otherwise left alone. Perforating cases needed pelvic drainage followed by

Fowler's position. The organism was generally a foul proteolytic germ. Fæces were not extravasated in the pelvis to any great extent on account of the obstruction of the diverticulum and the acute swelling surrounding it. There might be extravasation after separation of a slough. Stitching up was more likely to cause extravasation than to prevent it. There was no need to worry much; it was enough to anchor the appendices epiploicæ under the incision and drain. Nevertheless the ideal procedure, when it was possible, was a first stage Paul's operation, as this provided radical cure.

Chronic cases, correctly termed peridiverticular cellulitis, were amenable to careful treatment, but this was prolonged and irksome. The less nocuous lactic-fermenting intestinal flora should be encouraged by a low protein or wholly fruit and milk diet. Intestinal lubricants and lavage should be used to keep the stools soft. Roughage must be excluded. During active exacerbations glycerin per rectum was very useful. Cases should be regarded as "medical until proved surgical." Did diverticulitis, he asked, in fact recur elsewhere after excision? Persistence of pain, fever and obstruction, fistulæ and relapses were the chief indications for surgery. The Paul-Mikulicz method was the preferable one. Colostomy was necessary in severe pelvic matting and vesico-fistula.

Mr. M. F. NICHOLLS agreed that perforation did not cause gross infection and quoted a case in which the peritoneal exudate had been sterile and the diverticula had recovered without local treatment. A curious abdominal catastrophe was very likely to be a diverticulitis.

Prof. PATERSON ROSS spoke of the difficulties and dangers of vesical fistula. In one case a colostomy had been closed after six months and the fistula into the bladder had promptly reopened.

Mr. BURGESS agreed that there was no continuous leakage in diverticulitis any more than in appendicitis, but communication might reopen when inflammation subsided, and go on indefinitely, as it did in vesico-colic fistula. The colon was far more septic in diverticulitis than in cancer, and any attempt to free it was very dangerous. A transverse colostomy was the best operation, and it might have to be postponed for six or twelve months. Any septic part became aseptic if completely short-circuited; therefore the transverse colon must be cut completely across and the ends separated. Eventually any desired operation could be done to clear up the condition.

The PRESIDENT corroborated the suggestion that diverticulitis might end in carcinoma, and said he had also found it to cause obstruction.

ROYAL ACADEMY OF MEDICINE IN IRELAND

At a meeting of the section of medicine on Dec. 13th, 1935, with Dr. V. M. SYNGE, the president, in the chair, a paper on the

Infective Factor in Rheumatic Fever

was read by Dr. W. R. F. COLLIS. He showed charts demonstrating the following points:—

(1) Rheumatic fever follows acute hæmolytic streptococcal throat infections in a high percentage of already rheumatic subjects and in a small percentage of non-rheumatic patients.

(2) Both recrudescences and primary rheumatic attacks follow hæmolytic streptococcal infection only—not other infections.

(3) Rheumatic subjects are hypersensitive to the streptococcal endotoxin.

(4) In every case there is a definite sequence: acute pharyngitis → silent period (10–20 days) → acute rheumatism.

(5) Although the organism disappears from the surface of the pharynx soon after the pharyngitis subsides it can be obtained many months afterwards at autopsy from the centre of the tonsils, from the cervical and mediastinal glands, and occasionally from the spleen.

(6) Hæmolytic streptococci may be divided into biological groups: some of these cause throat infections which precede rheumatic fever; others do not.

(7) The blood of patients with acute rheumatism shows streptococcal antibodies (e.g., precipitins and anti-streptolysin). These are present while the disease is active but are low or absent during good health.

(8) There is a definite resemblance between the arthritis of serum sickness—which follows 10–20 days after injection of horse serum and occurs when the antigen (horse serum) and the antibody (precipitin) reach a certain titre in the patient's blood—and that of the acute rheumatic recrudescence.

Dr. Collis submitted that the infective factor in rheumatic fever is the hæmolytic streptococcus, and that the disease is due to interaction between breakdown products of the organism and the liquids and tissues of the body.

The PRESIDENT said he was interested to note Dr. Collis's remark that antibody production might be delayed by the giving of aspirin, and that this might prevent cardiac complications. If toxin-producing streptococci were the cause of rheumatic fever it seemed queer that scarlet fever should never be followed by the rheumatic type of valvular disease.

Dr. R. E. STEEN was not absolutely satisfied that the hæmolytic streptococcus was the cause of the rheumatic relapse. If a hæmolytic streptococcal sore-throat was the cause of acute rheumatism, it was surprising that one so seldom saw acute nephritis as a complication.

Dr. G. C. DOCKERAY pointed out that the incidence of streptococci in throats was very high.—Dr. L. ABRAHAMSON also referred to cases in which hæmolytic streptococci were present in the throat but the patients had neither clinical sore-throat nor rheumatism. It was sometimes stated that acute rheumatism was seen only in the poor, but this was not altogether true; he saw a good deal of it in private practice.

Dr. ALAN THOMPSON said it was well known that the titre of antibody corresponding to a particular organism might rise in response to any non-specific pyrexia. He thought it quite possible that the clinical exacerbations of rheumatic fever merely stimulated the rise of the streptococcal antibodies. In his opinion the experimental work described by Dr. Collis required considerable amplification before it could be accepted definitely.—Dr. J. C. FLOOD suggested that the work should be carried a stage further by trying to reproduce the lesions in animals.

Dr. COLLIS, in reply, said he fully realised that his hypothesis could not be accepted out of hand. The most important fact established was the association of the hæmolytic streptococcus and acute rheumatism. Criticism had centred chiefly on two points: (1) that the organism was often found in the throat of normal people and often caused acute pharyngitis unassociated with rheumatic fever; (2) that his hypothesis did not satisfy Koch's postulates or the generally accepted principles of disease processes. In reply to the former, he pointed out that the same could be said of nearly all germs found in the nasopharynx; recent work had shown

that many very different organisms are at present included under the wide heading of "hæmolytic streptococci," and in future the mere hæmolysis of blood corpuscles would not be sufficient description for these organisms. As to Koch's postulates he could only say that he thought they were dead. It had been shown that erythema nodosum could in different circumstances be caused by infection with different organisms. A new and revolutionary attitude was needed towards disease, for the reactions of the body were as important as the invading germs in the causation of disease syndromes.

Dr. ABRAHAMSON and Mr. J. OWENS each reported a case of Syphilis of the Lung.

Genital Prolapse

Dr. J. F. CUNNINGHAM's presidential address to the section of obstetrics and gynæcology dealt with the choice of operation in the treatment of genital prolapse. No one type of operation, he said, was effective for every degree and type of prolapse, and the cause of the condition should be carefully investigated in every case. He had found five different operations useful, with occasional slight modification. Simple colporrhaphy and perineorrhaphy was adopted for cases of small cystocele and rectocele when the tissues were good and the fascia capable of being repaired, and where there was no definite prolapse of the uterus. The Manchester operation was used in cases of uterine prolapse of the first or second degree, especially during the child-bearing period; but in patients near or past the menopause, where a large cystocele was the main feature, the interposition operation was preferred as being more certain in the ultimate result. Cases subjected to this operation must be carefully selected and the operation performed with close observance of detail, if unsatisfactory results were to be avoided. Vaginal hysterectomy, after Mayo, or combined with a Manchester colporrhaphy, was performed in cases of complete procidentia; this gave the best results, but attention must be paid also to the repair of the posterior vaginal wall and Douglas's pouch. Finally, Le Fort's operation was occasionally useful in elderly subjects where a more extensive operation might be dangerous. Dr. Cunningham quoted 161 cases operated on for prolapse; 121 by colporrhaphy (including Manchester), 16 by interposition, 19 by vaginal hysterectomy, and 5 by Le Fort's method. There was one death, from lobar pneumonia, and, on inquiry, 7 recurrences had been reported, 3 being in cases of colporrhaphy followed by one or more subsequent deliveries at term. Two were genuine recurrences, one was urinary incontinence, and one was a cervical hypertrophy. The conclusions drawn from the series were that colporrhaphy is unreliable, especially in elderly patients with atrophic pelvic fascia, but is the best type of operation in younger patients whose tissues are good. Interposition is excellent, but only in selected cases. Vaginal hysterectomy should be done in very bad cases, especially where the uterus is diseased.

Dr. GIBBON FITZGIBBON said he was glad that the President laid emphasis on the place of vaginal hysterectomy in cases of genital prolapse. A cause of confusion was the association of cystocele, rectocele, and prolapse all under the term "prolapse." The three were individual entities and needed definition. It was in cases of high rectocele that removal of the uterus enabled the uterosacral ligaments to be reached and incorporated with the lateral ligament in the restoration of the pelvic fascia to close the hernial

opening. The cure in these cases by operative treatment really depended on what part of the fascia was damaged, and the repair of that part of it. He did not believe in the necessity for the interposition operation. Where there was dropping of the cervix and cystocele, it was in his opinion never successful.

Dr. A. H. DAVIDSON said that since seeing the Manchester operation carried out in Liverpool he had done most of his prolapse work by this technique and found it gave good results. He had supposed that abdominal operations for prolapse had disappeared, but in London recently he had seen ventral fixation done for prolapse of the uterus. He was not very favourably disposed towards the operation of interposition, but thought it had a place—though an extremely limited one—in cystocele. He did not believe that vaginal hysterectomy was a cure for prolapse. It seemed to him important to stress the ætiology of prolapse: it was usually due to extremely bad midwifery.

Dr. T. M. HEALY agreed that the interposition operation cured cystocele. The difficulty was that the patient had no guarantee that she would not afterwards get a descent of her cervix, and the cure of this condition was extremely difficult. Vaginal hysterectomy was not a cure for prolapse unless the supports of the uterus were used to keep up the bladder, and the number of cases in which vaginal hysterectomy was necessary to cure prolapse of the bladder were relatively few. If anything was wrong with the uterus it should be removed, otherwise removal was unnecessary if the Manchester operation had been properly learned and if the technique was carefully carried out. Abdominal fixation of the uterus was good in elderly women with prolapse of the vagina, and a small uterus, when short anaesthesia was desirable.

Dr. O'DONEL BROWNE thought there was no doubt that anterior colporrhaphy and perineorrhaphy would cure cystocele and rectocele with one exception—high rectocele. Most of the cases in which good results were obtained by shortening the ligaments were cured by fibrosis. Prolapse of the rectal canal could be cured by injections of absolute alcohol.—Dr. A. W. SPAIN said he got very good results from the Manchester operation; any trouble he had was in the posterior wall. He thought that patients should be kept in bed for three weeks beforehand and given hot vaginal douches. He would never remove the uterus unless it was absolutely necessary to do so, and if a woman in the child-bearing age could be kept comfortable by the insertion of a pessary this ought to be done.—Dr. BOUCHIER HAYES believed that the whole question was really one of pelvic fascia and fibrosis.

Dr. R. M. CORBET said it was possible to have a cystocele without any prolapse, and it seemed to him unnecessary to push up the bladder and shorten the ligaments unless those ligaments appeared to be lengthened. He was rather in favour of vaginal hysterectomy for the larger type of prolapse; he agreed with Dr. Healy that it was not the hysterectomy but the bringing together of the ligaments that did good. He would advise spending more time in the preoperative treatment of these cases. Operation for high rectocele should if possible be postponed until the child-bearing period was over.

Dr. BETHEL SOLOMONS said that the Manchester operation suggested the conclusion that the main thing in dealing with prolapse was to shorten the tissues about the cervix and to repair the hernias, from which he had evolved his present technique—

namely, (1) a high amputation of the cervix with shortening of the uterosacral ligaments; (2) approximation of the bladder pillars with an extensive anterior colporrhaphy and colpoperineorrhaphy. The results had been good in his own hands and in the hands of some of his assistants. Le Fort's operation was excellent for the old patient, but he did not believe that any abdominal operation was necessary, and unless the uterus was diseased hysterectomy should never be done.

The PRESIDENT, in replying, said he was not an advocate of drastic surgery in prolapse cases, and was not enthusiastic about vaginal hysterectomy or interposition. The important thing for keeping the organs in place was the fascia. He had at one time done interposition; then he had got enthusiastic about the Manchester operation and had done it; but now he had gone back to interposition. If the uterus was too big he did some other operation, and if it was too small he never did an interposition. He did not think the operation suitable in cases of proclitica. Vaginal hysterectomy alone did not cure prolapse, and he regarded ventral fixation as a bad operation for prolapse.

MANCHESTER MEDICAL SOCIETY

At a recent meeting of this society Prof. A. D. MACDONALD, opening a discussion on the

Choice of an Anæsthetic

said that the ideal local or general anæsthetic has yet to be discovered. Only the volatile anæsthetics possess the controllability which makes possible the adjustments to varying needs and varying susceptibilities. The action of mixtures of aliphatic compounds is the sum of the actions of its components; there is no evidence of potentiation, such as exists for morphine and other alkaloids followed by anæsthetics. The use of mixtures, such as A.C.E. and Schleich's, in which the volatilities of the components differ widely, is pharmacologically unsound. Premedication with non-volatile drugs is only justifiable in doses well below the average anæsthetic dose; it is possible that some may affect vital centres before they depress ordinary reflexes.

Dr. E. FAULKNER HILL, in all grave risks where time allowed, would invoke the aid of surgeon, physician, and biochemist as well as anæsthetist to estimate the survival power of the patient, and then enhance this power to the utmost by suitable preparation, diet, rest in bed, and appropriate treatment before operation. In the course of time this would lead to a coördinated and unbiased opinion of the merits of the various methods in common use. But the organisation of such a service would seem to call for the appointment of a special officer.

Mr. GARNETT WRIGHT, from a small personal experience of splanchnic anaesthesia, was hopeful that by its use (1) chest complications might be much reduced, (2) palliative gastrectomy for carcinoma might be safely undertaken more frequently, (3) operation for acute hæmorrhage might be rendered safer.

A lively discussion followed.

TIVERTON AND DISTRICT HOSPITAL.—An up-to-date operating theatre, an X ray room with new plant, and an anaesthetising room are being added to this hospital which has been much enlarged during the last few years. The new extensions will cost about £3000.

REVIEWS AND NOTICES OF BOOKS

Milk : Production and Control

By W. CLUNIE HARVEY, M.D., D.P.H., M.R.San.I., and HARRY HILL, M.R.San.I., A.M.I.S.E., M.S.I.A., Medical Officer of Health and Sanitary Inspector respectively, Borough of Southgate. London: H. K. Lewis and Co., Ltd. 1936. Pp. 555. 21s.

THE different aspects of milk are so numerous and the literature on the subject so vast that it is not really practicable in one volume even so large as this one to cover adequately every aspect of it. Many matters of importance are here ignored, but the authors have succeeded in writing a book of considerable value which covers, particularly on the practical side, all the essentials of milk production and control. It is on the scientific side—i.e., the basis upon which production and control must be founded, if sound methods are to endure—that the volume is inadequate. A saving of space on some of the technical points which are treated in unnecessary detail would have enabled rather more evidence on the scientific side to have been incorporated, giving the book a better balance.

As a practical handbook it can be praised with but few reservations. While critical enough in some directions, as for example on the subject of designated milks, the authors seem to be somewhat timid in exposing the essential defects in our present legislation. This diffidence is associated with a curious attitude to some recent studies upon milk. For example, when discussing designated milk and the classification of milk the authors do not refer to the important report of the Committee on Cattle Diseases issued by the Economic Advisory Council in 1934. That committee after the most exhaustive study and examination of expert witnesses agreed on a complete policy and made explicit suggestions as to the different standards for milk. The chapter on the Future of the Milk Industry might have been much more valuable if this report had been discussed. The impression left by the account of the Tuberculosis Order and Ostertag's method for reducing bovine tuberculosis is that these methods are capable of yielding good results if improved, whereas in fact they are now recognised to be unsound. The reason for the fact that Ostertag's method is not favoured outside Germany is that it has had no effect in reducing bovine tuberculosis.

As a practical guide to clean and safe milk production, however, this book will be extremely useful. Everywhere there is evidence of the authors' familiarity with this side of their subject. The chapter on the cowshed is particularly good, although many authorities will disagree with the contention that the value in double sheds of positions of head-to-head as against tail-to-tail is equally balanced. The dairy, clean milk production, and the distribution of milk are well discussed; a long chapter deals in great detail with the treatment of milk by heat, and not very well-known processes such as stassanisation and pasteurisation in the bottle are explained. The important matter of the control of pasteurisation plants by the inspector is fully described, but the possible defects of such plant and the ways to detect them are not detailed, while some essential points are omitted. Existing legislation is conveniently set out, as are also the essentials of laboratory and other control. The section on chemical analysis seems out of place, for analysts would hardly refer to it and its omission would have enabled some of the

bacteriological laboratory problems to be discussed in more detail. The important phosphatase test is not even mentioned. Other chapters deal with the composition of milk, milk and disease, and the cow.

The monograph will certainly be found useful by medical officers of health and sanitary inspectors, while those concerned on the commercial side will find much instructive matter in its pages. The book is clearly printed and written in an attractive manner; the views expressed will be accepted by authorities as sound in the main, while there are many valuable illustrations. The bibliography is rather a poor affair.

Optical Rotatory Power

By T. MARTIN LOWRY, C.B.E., M.A., D.Sc., F.R.S., Professor of Physical Chemistry in the University of Cambridge. London: Longmans, Green and Co., Ltd. 1935. Pp. 483. 30s.

THIS book is a record of work and progress in polarimetry extending over a period of 120 years, from the original discovery of the optical rotatory power of quartz to the recent theoretical work of Max Born in Cambridge. It is a complete exposition of the subject by one who not only knows all its complexities, but has himself contributed much of the original work described. The first part of the book is mainly historical, but contains an interesting general account of the principles of rotatory polarisation. A reader with little knowledge of the subject will be able to appreciate and understand its elements. The work of Pasteur forms the basis of this section and reminds us that a man to whom medicine is greatly indebted has also contributed largely to an almost unrelated branch of science. The second part deals with the practice of polarimetry, of which the applications are almost unlimited. The measurement of rotatory dispersion in both the ultra-violet and infra-red portions of the spectrum is clearly dealt with and a description is provided not readily available elsewhere. The book concludes with a theoretical account of the subject, which of necessity assumes an adequate knowledge of mathematics in the reader.

Prof. Lowry has produced a book on a difficult subject that is admirable both in intention and execution.

The Microscopic Anatomy of Vertebrates

By G. G. SCOTT, Ph.D., Professor of Biology, City College, New York City; and J. I. KENDALL, Ph.D., Instructor in Biology in the College. London: Henry Kimpton. 1935. Pp. 306. 17s. 6d.

HUMAN anatomy is made both more intelligible and more interesting if taught from a comparative standpoint. The same could be said of histology, though in this case the comparative method has seldom been applied. The chapters of this book deal separately with the microscopic structure of the main vertebrate organs. In spite of the authors' implication to the contrary in their preface, the emphasis is placed entirely upon mammals. The brief account of the particular organ as found in the lower vertebrates, which in some places precedes a description of the mammalian structure, is seldom full enough to afford a valuable comparison. Neither the evolutionary nor the functional significance

of the changes in microscopic structure is emphasised. In several instances, a notable example being the pineal body which has a particularly interesting evolutionary history, no mention whatever is made of the structure as found in the lower vertebrates. There is little value in descriptions of a variety of types unless relationships are discussed. This book will certainly provide a useful introduction to mammalian histology, but the authors have not succeeded in presenting the subject in a truly comparative manner.

A Companion to Manuals of Practical Anatomy

Fourth edition. By E. B. JAMIESON, M.D., Senior Demonstrator and Lecturer on Anatomy, University of Edinburgh. London: Humphrey Milford, Oxford University Press. 1935. Pp. 661. 12s. 6d.

HERE, packed into small space, is a mass of detailed and highly accurate information. The section on the central nervous system is worthy of special mention. The adoption of the English terminology (Birmingham revision) has doubtless contributed to the success of this little book which is as useful a pocket manual as anyone could wish for.

Minor Medical Mysteries

By LEONARD WILLIAMS, M.D. Glasg. Foreword by Lord HORDER. London: Cassell and Co., Ltd. 1935. Pp. 211. 5s.

Dr. Leonard Williams is well known as an accurate clinical observer, possessing clear-cut and often individual views, and as a pungent writer. These qualities appear in his latest collection of essays in which, however, he hardly does himself justice. The reason for this may be that many of the essays were communicated to magazines where space has to be dictated by the editor to the disadvantage of the contributor. It is clear that when 30 medical or semi-medical subjects, all of a sort that invite discussion, are dealt with in 200 small pages, the author cannot develop his theme, and this will be a matter of regret to Dr. Williams's readers, because of the challenging nature of many of his statements and conclusions which are put down with wit and wisdom. Lord Horder's foreword is a just encomium.

Fifty Years a Surgeon

By ROBERT T. MORRIS, M.D. London: Geoffrey Bles. 1935. Pp. 276. 10s. 6d.

THERE have been many books published composed of personal reminiscences centring round the developments of medicine in the nineteenth century, but Dr. Morris's addition to their number has a claim to attention. It is well and brightly written, and the picture supplied of surgical advance in the United States is dramatic. We have a picture of a great American medical school in the 'eighties, and the revolution caused in the Bellevue Hospital, New York, by the introduction of antiseptics. The great advances in technique now made possible are set out, while the perfecting of the methods of administering anaesthesia are shown to have enormously extended the range of the surgeon's utility. There is nothing new in these chapters to the medical reader, but the general public should be edified by their contents. The personal record of private and special practice

is written with zest and leads to a chapter entitled "the fourth era in surgery," by which Dr. Morris means the appreciation in surgical treatment of the influence of the patient's own physiology. This is probably the section whose writing determined Dr. Morris on publication. It is an able but partisan denouncement of surgical interference where the chances of recovery without operative aid have been underestimated. And we learn with no surprise that some of the author's colleagues have not been in agreement with his views.

The book ends with chapters on such much-discussed topics as osteopathy and therapeutic fads, psycho-analysis, birth control, and certain forms of professional delinquency, where the opportunity for telling stories is happily made use of.

Diseases of the Liver, Gall-Bladder, Ducts and Pancreas

Their Diagnosis and Treatment. By SAMUEL WEISS, M.D., F.A.C.P., Clinical Professor of Gastroenterology, New York Polyclinic Medical School and Hospital. With a chapter on Surgery by J. PRESCOTT GRANT, M.D., F.A.C.S., M.R.C.S., Professor of Surgery, and a chapter on Roentgenology by A. JUDSON QUIMBY, M.D., F.A.C.R., Professor of Roentgenology at the same school. New York: Paul B. Hoeber, Inc. 1935. Pp. 1099. \$10.

Prof. Weiss has written this book at the request of his colleagues and students, and offers it as "primarily a practical one" to the medical student, the general practitioner, and "even the specialist." It is in the form of a large and fairly comprehensive systematic treatise. Historical, anatomical, and physiological aspects of the subject are briefly dealt with at the beginning. Descriptions of morbid anatomy appear in their proper places, but over-stressing of pathology is deliberately avoided. Clinical descriptions of disease, methods of examination—including large numbers of laboratory methods—and treatment occupy most of the book. It is profusely illustrated with drawings, photographs, and radiograms, all beautifully reproduced. Paper and print are beyond cavil; our only criticism of the production is that the book is uncomfortably large and heavy. Some of its bulk might easily have been reduced, since the white margin round every page is so excessively broad that its area exceeds that of the printed part.

The text is curiously unsatisfactory. Its English style, when due allowance has been made for recognised Americanisms, often lacks the precision that should characterise a scholarly work; the clay- or putty-coloured stool of obstructive jaundice, for example, is repeatedly described as "discolored." Where the author is noting his own observations, or clinical conditions familiar to him, he is naturally happier, but much of his material is drawn from the literature, and interjected in the form of short paragraphs; critical appraisal of these contributions and synthesis of them into a coherent picture is often wanting, and at times indeed an entirely wrong impression emerges. Thus under the heading "pancreatic diabetes" a two-page account of diabetes is included for the sake of completeness, and it opens with the sentence, "The causes of diabetes are the causes of obesity, the two conditions being constant companions"; this is surely an overstatement even of Joslin's view. In "bronzed diabetes hæmochromatosis" it is said that the skin and organs are red-brown—in most cases the skin is actually leaden-

grey—and that in the final stage of the disease diffuse carcinoma of the spleen is common. Even where the author draws directly on his own experience he is often disconnected and unconvincing, as where he describes a case of thyrotoxic auricular fibrillation with congestive heart failure and hepatic enlargement to illustrate the connexion between gall-bladder disease and cardiac pain. This sort of muddled presentation is so pronounced in the chapter on cirrhosis of the liver that it must reflect a confusion, and therefore an inaccuracy, of thought. A broad classification into “Laennec’s cirrhosis (atrophic, portal, multilobular)” and “Hanot’s cirrhosis (hypertrophic, biliary, monolobular)” is first adopted. The author then describes a number of varieties of cirrhosis, whose relation one to another is by no means clear, and the reader, among other uncertainties, has no means of telling whether the two separate descriptions, of “simple hypertrophic cirrhosis (Hanot-Gilbert)” on pp. 417–420, and of “biliary cirrhosis (Hanot’s syndrome)” on pp. 430–438, refer to the same disease or not.

The book as a whole contains a great deal of valuable material, but it seems to have been put together by a hurried compiler rather than built by a careful architect, and on that account it does not fully justify either the beauty of its production or the labour that has gone to its preparation.

Streamline for Health

By PHILIP B. HAWK, Founder of Food Research Laboratories, Inc. New York and London: Harper and Brothers. 1935. Pp. 186. 10s. 6d.

Dr. P. B. Hawk will be remembered as one of the collaborators with Refuss in certain fundamental physiological inquiries which were published in the American medical literature soon after the war. His system for safe weight reduction consists chiefly in a low calorie diet based on cow’s milk, orange juice, and lettuce, and of periods of repeated fasting, or semi-fasting, with restricted diet in between them. Some would call the style of this book racy, others would say that it was full of frank Americanisms. In any case the language is such as to make little appeal to the majority of English readers. This is the more regrettable because it is essentially one of the sounder books on weight reduction recently published. Readers who can struggle through chapters with titles such as “Is Science cockeyed? Hay! Hay!” will find accounts of many instructive experiments and apt criticisms of many unscientific methods of “reduction.”

Russell A. Hibbs

Pioneer in Orthopædic Surgery, 1869–1932. By GEORGE M. GOODWIN. London: Humphrey Milford, Oxford University Press. 1935. Pp. 136. 10s.

Dr. Goodwin has written an instructive book about an interesting man. The story of Hibbs’s life is worth more attention than many of the medical biographies which reach the public to-day, for the reasons which led to his success call for record alike as a surgical innovator and a hospital administrator. Throughout a very busy life he seems never to have departed from the one idea which he set before himself—namely, to be a champion of the cause of the crippled child. All that he did centred round that object. With no private backing or influence, but rather by determination, he obtained a post in

an orthopædic hospital which needed reform and which, when reformed, would call for extension. He became immediately involved in a dispute with a superior officer, and to the disgust of that superior was held by the lay authorities of the hospital to be right. But many prominent members of his specialty resented the victory of the junior man and proved less than helpful to him when his private practice began to grow. The brief biography shows how Hibbs was able to overcome professional opposition and to reach a high position as an orthopædic specialist, although certain of his theories were never universally accepted. What they were, and how he gave practical effect to them, will be gathered from a series of cases, added as appendices, which make informing reading.

Genetics

By H. S. JENNINGS, Henry Walters Professor of Zoology and Director of the Zoological Laboratory in the Johns Hopkins University. London: Faber and Faber Ltd. 1935. Pp. 351. 15s.

MODERN genetics has given rise to more unwarranted and dogmatic generalisations than almost any other branch of science. At every stage in its development the particular facts have seemed to point in an attractive manner to far-reaching general conclusions. Popular books on the subject seldom describe the experimental evidence fully enough to allow the reader to judge for himself of the validity of these conclusions, and this is unfortunate in view of the interest taken by the educated public in the possible application of genetic principles to human affairs. The groundwork of the subject however, as Prof. Jennings points out, “involves detailed facts and relations which must be thoroughly grasped,” and the general reader who wants to be put into a position to form opinions is faced with some hard work.

Prof. Jennings gives a clear account of the chromosomal theory with continual reference to the original work on which the theory has been based. He does not doubt that in a stable environment all inherited characteristics are determined by the genes, which are borne in a linear fashion upon the chromosomes. Beyond this point he suspends judgment, presenting the facts and various different conclusions which might be drawn from them. He shows how the original idea of the fixed action of a gene is being rapidly undermined. There is now some evidence that the action of a gene is dependent upon its position in relation to other genes. Should this prove to be correct “it would require a reinterpretation of many of the accepted ideas of genetics.” The unsatisfactory state of our knowledge about the relative influence of hereditary and environmental factors on human characteristics is emphasised. The book concludes with two interesting chapters on genetic variations, natural and induced by radiations. There can be no doubt that many species have diverged from a common stock to a limited extent as a result of eliminations, reduplications, and translocations of chromosomes. But Prof. Jennings seems to be of the opinion that, whatever kind of variation has formed the basis of progressive evolution, the changes in the action of single genes which have so far been observed and are known as mutations have not necessarily thrown much light upon the problem. This is certainly an unorthodox suggestion, but it must be admitted that the mutation theory of evolution is by no means as firmly established as is often assumed.

THE LANCET

LONDON: SATURDAY, JANUARY 11, 1936

PHYSICAL EDUCATION

THE year 1935 will be a memorable one in the history of physical education in this country. The prominence given to physical fitness by the King's Jubilee Trust Fund has stimulated official and voluntary organisations concerned with gymnastics and games for children and young people to greater energy, while the need for recreative and enjoyable occupation for unemployed men and women in distressed areas has led to the setting up of schemes for physical training which, it is hoped, will be developed and extended to the great benefit of national health and physique. Physical training has been slow to receive adequate recognition in England. It first became a normal and regular part of the elementary school curriculum in 1909. Sir ROBERT MORANT, then secretary of the Board of Education, realised not only its importance to the health of the growing child, but its close association with the school medical service and hygiene. Therefore he entrusted the preparation of a revised syllabus of physical exercises to the medical department of the Board, and placed the newly appointed staff of special inspectors under the general control and guidance of Sir GEORGE NEWMAN. The progress of physical education may be read in the successive reports of the chief medical officer. A new syllabus was called for in 1919, and yet another in 1933; from time to time supplementary matter has been issued dealing with particular problems such as the organisation of games, the work in small country schools, the value of playing fields, and so forth; and there are other books now in preparation which will provide for the needs of the older boys and girls in the senior schools.¹

The general policy of the Board of Education has been to leave physical training in the elementary schools in the hands of the class teachers; to give all teachers some special training, but to encourage them to supplement this by attendance at suitable vacation courses and classes; and to support the appointment by local education authorities of expert organisers whose duties include general supervision of physical training and advice to individual teachers. This policy has been successful, but it is pleasing to note that the Board now appear to be pursuing it with greater energy, and that increased attention is being paid to secondary

education in this subject. Systematic physical training, as apart from games, has been seriously hampered in public and secondary schools for boys by the lack of trained gymnastic masters; even now there is only one training college for men—viz., Carnegie Hall, founded at Leeds a few years ago by a grant from the Carnegie United Kingdom Trust—whereas for 50 years there have been facilities for the training of women. Fortunately the growing demand for teachers and "leaders" is bound to result in more ample opportunities for training, as well as greater scope for employment after qualification. But the authority of the Board is limited to schools and educational work, and there is a strong feeling that much more might and should be done for the promotion of physical activity in its broadest sense, not only among young men and women, but among older persons of both sexes. The "keep fit" movement, for example, which originated in Sunderland and is rapidly spreading over the whole country (see p. 125), is providing healthy physical interests for hundreds of women, many of mature age, who had never experienced the joy of movement before. Gymnastic classes and games are doing the same for young men. The Central Council of Recreative Physical Training, a representative and voluntary organisation established early last year under the patronage of the KING and QUEEN and the presidency of Lord ASTOR, has been formed to coördinate and encourage all types of recreative activity.² The national playing fields association, organisation for the promotion of athletics, swimming, camping, hiking, as well as games, dancing, and gymnastics, are all combining to arouse a much wider appreciation of the value of exercise, open air, and sunshine, and to show that no one need feel too old or too stiff to enjoy some form of exercise.

In this country we have long been proud of our traditional games, though they have been played by the few rather than the many. Our system of gymnastics was borrowed mainly from the Scandinavian countries. But at long last we are beginning to develop a scheme of physical education of our own, which we hope will be characteristically national. We shall take full advantage of the experience and knowledge of other lands, but shall adopt, modify, and add to this so as to meet the needs of our climate, our social and educational conditions, and our national habits and customs. Physical education, wisely used, has an immensely important contribution to make towards a state of positive good health, which is something much better than the mere prevention of disease.

THE CYTOLOGICAL EXAMINATION OF MILK

THE microscopical examination of milk for tubercle bacilli is preferable to the biological test in so far as it is simpler and quicker. Unfortunately these advantages are counterbalanced by

¹ See the report of the C.M.O. of the Board of Education for the year 1934. H.M. Stationery Office. 2s. 6d.

² This council has just issued its first news leaflet, which may be had from the organising secretaries, 11, Doughty-street, London, W.C.1.

the fact that the organisms cannot be seen in milk under the microscope unless present in enormous numbers. According to D. R. WOOD¹ the microscopical test is 500 times less sensitive than the biological; and estimates of the same order have been made by other workers. Such comparisons refer to the classical method of examination which consists in laboriously searching smears of milk deposit under the oil-immersion lens for acid-fast bacilli; and the weary observer derives little comfort from the reflection that the finding of such organisms carries no assurance that they really are tubercle bacilli and not saprophytes. More recently attention has been turned from the direct examination of films for acid-fast organisms to the study of the cells found in milk and their relation to tuberculosis. H. L. TORRANCE² drew attention to the occurrence of certain more or less characteristic groups of cells to be found in tuberculous milk. Other workers have confirmed these findings, and S. T. COWAN and L. MADDOCKS³ now report the results of a careful study of the cytology of 229 samples of milk from single cows. If centrifuge deposit is spread in a thin film and stained the cells are for the most part distributed uniformly over the whole surface; but here and there clumps of cells are encountered. These may be composed of endothelial cells, non-endothelial cells, or of a mixture. COWAN and MADDOCKS found that whilst such cell groups might be present either in tuberculous or non-tuberculous milk, more of them, particularly of the endothelial type, were observable in tuberculous milk. It was also found that in tuberculous samples acid-fast bacilli showed a tendency to collect near the cell groups; bacilli lying far away from these groups were more likely to be non-pathogenic ones. Thus a large surface of a smear may be looked over rapidly under a low magnification, and the areas containing endothelial cell groups can then be subjected to examination for the presence of acid-fast bacilli under a high magnification. The 229 samples examined in this way by COWAN and MADDOCKS were also tested on guinea-pigs. From 38 of them tuberculosis was produced in these animals, in 7 of these cases the degree of contamination being slight if judged by the extent of the lesions produced. By microscopical examination acid-fast bacilli associated with cell groups were found in 21 samples. None of the 7 lightly contaminated samples was detected in this way. In 2 samples acid-fast bacilli were found unrelated to cell groups, and were given a preliminary label of saprophytes, this diagnosis being confirmed later by guinea-pig inoculation. Tubercle bacilli were never found in the complete absence of cell groups and only rarely in association with groups containing no endothelial cells. No positive results were obtained by microscopical examination which were not confirmed by biological test. It emerges that attention to the cytological picture is a most useful preliminary to the microscopical examination of samples of milk

from single cows, for evidence of contamination by the tubercle bacillus increases considerably the proportion of positive results obtained. Even in its improved form, however, this method is not sufficiently sensitive to justify the omission of guinea-pig inoculation, while when bulk milk is being tested it is of very little value.

The cytological study of milk is not confined to the diagnosis of tuberculosis. Attempts have also been made to diagnose other forms of mastitis, in particular the economically important streptococcal form, by this means, but the value of the method is still in dispute. In extreme cases no difficulty arises; milk containing enormous amounts of leucocytic deposit clearly comes from an abnormal udder, whilst a sample which contains no leucocytes has probably come from a healthy udder. In intermediate cases interpretation of findings is more difficult, for it has frequently been noted that in milk from healthy udders the cell count may be high during the late colostrum period and when drying off, though low at other times. It is thus necessary to have a full history of the cow from which the sample comes. Where milk from several cows has been mixed the high cell content of one fraction may be cloaked by dilution with normal milk. A differential cell count is of far greater value than a total count in judging the quality of milk. A high cell count including erythrocytes, monocytes, eosinophils, or pus cells showing phagocytosis suggests inflammatory changes, whereas desquamated epithelial cells, round cells, and neutrophils are less significant. Differential counts are, however, tedious to carry out and require considerable experience, whilst the dilution factor still comes into play.

One of the most serious defects of the cytological examination of milk as a diagnostic measure is that even where inflammatory exudate can be demonstrated, evidence is still lacking as to the cause of the inflammation, except on the comparatively rare occasions when it is possible to demonstrate the causal organism microscopically. Inflammatory exudate may be found in cases of mastitis, due to the tubercle bacillus, the streptococcus, and the staphylococcus as well as in other less important types of mastitis. Of these infections, contamination of milk by *B. tuberculosis* is of course a danger to public health. Streptococcal mastitis is of importance from the point of view of health of the consumer only in so far as such infection may affect the nutritive quality of the milk; but from the economic aspect such infection is of immense importance to agriculture. Staphylococcal mastitis is relatively unimportant economically but may have a public health significance. The significance of the mastitis in short depends on the nature of the causal organism, which for the most part can only be ascertained by resort to other methods. The microscopical examination of milk may sometimes prove a useful and a rapid aid to diagnosis, particularly in tuberculous and occasionally in other types of mastitis, but such an examination is not an adequate substitute for cultural or biological tests.

HISTIDINE TREATMENT OF PEPTIC ULCER

THE multiplicity of the methods of treatment devised for peptic ulcer emphasises alike the incompleteness of our knowledge and the need for caution. The chronicity of the disease, and its tendency towards relapse and remission, make it an awkward subject for therapeutic investigation, and we are also handicapped by the difficulty of reproducing in animals the typical chronic ulcer found in man. Among the more interesting of the remedies now on trial is the amino-acid histidine, given by injection. The work on which its use is based begins with observations of MANN and WILLIAMSON in 1919, when they found that if the duodenal secretions of dogs are diverted into the lower end of the ileum the animals soon develop peptic ulcers like those of human beings, and severe nutritional disturbance leading to death in a few weeks. ARON of Strasbourg, repeating these experiments (with WEISS) in 1933, reported¹ that of five animals thus operated on two died with ulcers whereas the other three, which had received histidine and tryptophane injections, showed no ulceration at all. These injections were given in the belief that the development of ulcers in the dogs was in some way due to amino-acid deficiency resulting from the surgical interference with protein digestion. Further work led ARON to apply his theory to the treatment of peptic ulcer in man, and using intramuscular injections of a 4 per cent. solution of histidine hydrochloride—prepared by Messrs. Hoffmann-La Roche under the name of Larostidin—he reported very good results in 17 cases. Since this first paper by ARON and WEISS appeared in 1933 some eighty other records of the use of larostidin have been published in America, Germany, Italy, and other countries. The new form of treatment has been adopted with unusual readiness because its advocates have claimed from the first that it largely, if not wholly, takes the place of diet, alkalis, and rest in bed. Such claims demand even more careful study than those made for remedies which are merely ancillary to the better established therapeutic measures.

It will be generally admitted that, whatever the treatment, medical or surgical, the ultimate prognosis as regards cure of peptic ulcer is at present none too good. Statistics of permanent cure vary between 50 and 90 per cent., but if a long enough margin is allowed—it cannot be less than five years and should properly be much more—the final percentage is probably not above 75, and less for duodenal lesions. On the other hand, almost all forms of treatment seem capable of producing temporary improvement in almost every uncomplicated ulcer. Simple dieting may bring immediate relief; moderate or massive alkali treatment, duodenal feeding, and sometimes merely rest and freedom from worry, will often do the same. For many years, since HOLLER first recommended injections of protein in 1921, various forms of parenteral therapy have been recommended and

widely used in support of dietetic or other régimes. Among them, vegetable proteins, milk, vaccines, emetine, pepsin, and many others have been given favourable reports. Indeed, it seems that non-specific protein therapy may be expected to hasten healing and lower gastric acidity, and these are grounds for using it. Histidine treatment differs from the others because it is based upon the view that peptic ulcer is at least partly a deficiency disease, and that injection of this amino-acid will correct part of the deficiency. It does not appear probable, however, that the diet of the patient, who afterwards gets an ulcer, is consistently deficient in protein—in fact many are normally big meat-eaters—and if such deficiency arises through faulty digestion or absorption of proteins no cause for the failure is yet known. The effects of drastic interference with the digestive secretions of dogs cannot be applied to man without reserve, and the rationale of histidine treatment requires further support. Judgment of its value must therefore be formed largely on clinical experience.

The dose recommended is 5 c.cm. of a 4% solution histidine hydrochloride given daily by intramuscular injection for a period up to three or four weeks and repeated as required. There are said to be no dangers, the patients need not be kept on a restricted diet, alkalis are unnecessary, and rest in bed is usually not required. Relief from symptoms follows as a rule in two to six days, and some 60–90 per cent. of cures are recorded. But as most workers point out—for example, BULMER² and SMITH³ in this country and RAFSKY,⁴ EADS,⁵ BOGENDÖRFER,⁶ and WEISS⁷ abroad—it is far too early to assess the value of this treatment. Already some disappointing relapses are known and there will probably be general agreement with IZAR⁸ that histidine is not a specific remedy for peptic ulcer, in the sense that it does not counteract the cause. If this is so, it must seem unwise to relax attention to dietetic and general measures while carrying out injection treatment. The longest case-histories hitherto reported are less than two years, and the word "cure" is therefore inappropriate to any of them. At the same time the many accounts of relief of symptoms, increase in weight and well-being, and removal of clinical and radiographic evidence of active ulceration point to the treatment being in some way beneficial. Whether its action will turn out to be in any sense specific or is merely (as seems likely) comparable to that of other injected substances, and whether it can lead to lasting cure or replace other therapeutic measures, are questions that can be decided only by further study. The time has not yet come for accepting an entirely new theory of ulcer-causation, and for abandoning the ordinary rules of diet and management.

THE BAR ON THE CORONER

THE General Council of the Bar would insist upon the necessity of a legal training for coroners. It also protests against the action of certain important local authorities in stipulating that the coroners whom they appoint must have a dual qualification in law and medicine. So much we learn from the annual statement of the Bar Council wherein is reported a summary of the barristers' official representations to the Home Office Committee now inquiring into the law and practice relating to coroners. The Bar does not want to see inquests abolished, but it wants them brought into line with other courts. Its demand for recognition of the right of barristers and solicitors to examine and cross-examine witnesses before coroners was inevitable. In practice this right is conceded already save in extreme cases where legal representatives get at loggerheads with their tribunal. Another by no means revolutionary recommendation is the demand that committal for trial upon coroners' inquisitions be abolished. Such committals have been greatly diminished by the 1926 Act, and they are sometimes made to look a little forlorn at the resultant prosecution. The solemn extravagance and anticlimax of Lord DE CLIFFORD'S trial in the House of Lords last December might never have been staged but for a coroner's committal. It is a question of expediency whether the rare occasions when these committals catch a criminal who would otherwise escape are sufficient justification; there are, of course, plenty of committals from other courts than the coroner's which prove abortive.

The Bar Council's demand for adherence to the strict rules of evidence is a more awkward business. A great part of the coroner's usefulness to the community is his power of sifting local gossip in

cases of suspected crime. In almost every court of law some bit of technically inadmissible evidence sometimes slips in and is consciously disregarded. There seems no reason why a coroner should not be trusted to distinguish between good and bad evidence. When the police make preliminary inquiries, they are glad enough to listen to hearsay, and it may well be that those responsible for bringing our criminals to justice will successfully object to the Bar Council's proposal. The mysteries of the strict rules of evidence—one of the causes why it is popularly believed that the truth does not always emerge in a court of law—are based on the fact that certain parties are admitted to the legal proceedings and certain issues have been carefully defined beforehand as the case which the court is to try. It is not going to be a simple matter to practise these mysteries at an inquest where it is often the coroner's task to find out what parties may be concerned and what issues may be expected to arise. Naturally the more complicated the procedure the greater the need for legal coroners and legal intervention at inquests. But if the inquest is to be converted into something like an inquiry before a stipendiary magistrate, it will cease to be the institution which has proved its usefulness by surviving through so many centuries.

Which are the better coroners, doctors or solicitors? It is doubtful whether persons who are in a position to decide the question would venture any sweeping generalisation in reply. The public, at any rate, probably detects little difference between a solicitor-coroner with a knowledge of medicine and a doctor-coroner with a knowledge of law. Best of all is the coroner who is duly qualified in both law and medicine. Yet it is this dual qualification which the Bar Council cannot abide. There is, it seems, nothing like leather.

ANNOTATIONS

PSYCHOGENIC FACTORS IN ASTHMA

Two papers in the *Guy's Hospital Reports* describe an important advance in the understanding of the asthma-eczema-prurigo syndrome. The work on which they are based was stimulated by the experience—already mentioned in reports to the Asthma Research Council¹—that in intractable cases children sent to a convalescent home show immediate improvement and remain in good health until they return to their own homes, when they relapse at an equally striking rate. The first paper² shows the factors concerned in this phenomenon and tells how clinical results proved that the psychological environment of child patients is as important as the physical. Moreover, one kind of personality is predominant among this group of cases. It is noted that, for example, in a group of enuretic children one finds almost any type of personality, whereas child sufferers from the asthma-eczema-prurigo syndrome present with unusual frequency a combination of high intelligence, ready manifestation of anxiety and insecurity, and strong tendencies towards aggressiveness and egocentricity.

On the parental side is found with similar frequency a nervous, over-anxious protective attitude that is plainly the cause of a part of the child's emotional state. Psychotherapy directed in accordance with these observations has been sufficiently successful for the writers to suggest that it has at least as much to offer as any other available kind of treatment for this type of asthma patient.

These results are gratifying, and the way in which the theoretical aspect of the subject is handled marks a forward step in methodology which raises the work well above the level of another addition to the numberless "cures" of asthma. The emotional determination of the asthma attack is no new discovery, but for some workers the mind-body antithesis has so great a hold that the demonstration of allergic phenomena excludes any need for psychological examination of a patient or, conversely, the curative effect of psychotherapy settles the problem of causation. Dr. Strauss³ claims as established the point that one cannot correctly talk about "true asthma" and "psychogenic asthma," and sets out as the object of research the evaluation of the degree in which the psyche participates in the asthmas in

¹ See THE LANCET, 1934, II., 1171.

³ Strauss, E. B.: *Ibid.*, p. 309.

general. References to his own experience show that asthma can be—or behave as—a symptom of conversion hysteria or an anxiety equivalent, but such cases are only on the surface of the problem. Dr. Rogerson² indicates its more profound difficulties when he notes the impossibility of separating the intellectual and temperamental endowment of the individual from his physical endowment, to disregard the one and call the other constitution. Apparent contradictions that have hitherto been used as arguments in controversy present themselves no longer as contradictions but as problems needing an answer. The appearance of allergic reactions in an infant of six months, for example, calls for an explanation of the curious clinical picture—a disabling physical illness from infancy which appears to respond to a modification of the psychic milieu.

This work, original as it is, does not stand alone. We have commented upon the results of the psychological examination of gastric ulcer patients by Draper and Touraine,⁴ who found throughout that group peculiarities which marked them, like these asthma subjects, as possessing a specific personality picture. Similar results have been claimed in the examination of migrainous subjects, and apart from possible therapeutic applications, all these observations point to some underlying general principle the discovery of which may perhaps give a new direction to the study of physiological processes as influenced by that indefinite something that we call the psyche.

"CHRONIC CYSTIC MASTITIS"

DESPITE repeated efforts on the part of various writers to clarify the subject, by changes in nomenclature and by fresh conceptions of the underlying pathology, there still exists much confusion about that condition of the breast which used at one time to be labelled and dismissed without more ado as "chronic cystic mastitis." Two conflicting views now held by different schools of thought have never been adequately balanced—one that the disease is characterised by such an aberrant type of epithelial activity as to make carcinomatous change a dangerous possibility in every case; the other, that chronic cystic mastitis is essentially an exaggeration of a normal physiological change, and that malignancy, when it does complicate the simple disease, is as fortuitous as it is in the "normal" breast. The former view is upheld vigorously by Cheate and Cutler⁵; the opposite opinion, at least as regards the likelihood of malignant change in the affected breast, was re-stated only recently in our columns as the experience of Mr. Eric Pearce Gould.⁶ The outcome of this disagreement is that when a surgeon meets with the common type of "lumpy" breast, he is embarrassed by the knowledge that whatever line of treatment he may advise is open to serious criticism. Dr. Percy Klingenstein⁷ in a recent paper draws comfort from a statement of Bloodgood's that cases of doubtful malignancy treated by radical operation have done well. Klingenstein himself does not advise such drastic measures. He quotes figures to show that conservative surgery has a definite place in the treatment of "chronic mastitis." Where some may be inclined to join issue with him is in his recognition, with Cheate, of "mazoplasia" as a physiological state, as distinct from cysts and intracystic and intraductal papillomata, which he regards as of true neoplastic forma-

tion. J. S. Rodman⁸ is much impressed with the extent of epithelial development and involution characteristic of the menstrual cycle. There does not seem to be any sound proof that the glandular menstrual changes in the breast are as profound as he believes. E. K. Dawson's⁹ observations on normal breast tissue have, in fact, led her to an opposite conclusion. While the gaps in our knowledge of normal breast histology and physiology are still so wide, it is a matter of difficulty to interpret the more generalised states of epithelial change, particularly, perhaps, in patients before the menopause.

The observations of Mr. Harold Burrows¹⁰ are suggestive. He found that in their response to oestrogenic substances, the breasts of some of his mice showed more pronounced hyperplasia and less marked cystic dilatation, while in others a pronounced dilatation was accompanied by relatively little hyperplasia, that, in fact, the two conditions seemed to occur in inverse ratio. As far as these experimental results go, they suggest that cyst formation in itself, though pathological, may be found actually to carry a more favourable prognosis than hyperplasia of the epithelium, for Burrows has found the latter condition to result from a more prolonged administration of oestrin, and to be a later effect than is cystic dilatation. It seems likely that the *localised* lesions of the breast, such as adenomata (whether of the fibro-adenoma, or the adeno-fibroma type); blue-domed cysts; papillomata; and intracanalicular fibromata, are in pathogenesis more similar to "chronic cystic mastitis" than was at one time generally thought. Encapsulation of these tumours may be very imperfect, as is well known to the surgeon who attempts their removal under local anaesthesia. A more or less generalised change in the surrounding breast tissue is not infrequent. In sections right through a breast which is the site of "chronic cystic mastitis" all the above changes—papillomata, fibrosis, cysts, and adenomata—may be found in miniature, as it were. This consideration complicates the treatment of tumours clinically localised. Rodman regards all these changes as aberrations due to interference with the proper growth and involution characteristic of the sexual cycles.

When we attempt to come to conclusions about the prognosis and treatment of this condition, we meet the further difficulty that the criteria are missing on which, in individual cases, the transition from simple to malignant hyperplasia may be decided. Also—and it should be possible in time to fill this gap in our knowledge—there is a great paucity in the literature of follow-up results of cases treated by the more conservative measures. What we want to know is whether these patients return later with cancer. Klingenstein followed 54 patients who had been treated by partial breast excision, and found that, with two exceptions, they remained free of malignancy for periods of 2–11 years. The two exceptions developed cancer of the breast, one seven years and the other one year after operation. Klingenstein quotes a report of Greenough and Simmons on 83 cases of cystic mastitis, treated by local operation, in 4.8 per cent. of which cancer later developed. Rodman follows Cheate in accepting the incidence as being 15–20 per cent. in patients over 35. He advises watching patients over this

age for two months. If a lump in the breast, which has been diagnosed as benign, does not in this time show evidence of disappearance, he advocates simple amputation. In patients under 35, he would watch for changes in the swelling before, during, and after the menstrual period; if there is no change he would amputate. The significance of a serohæmorrhagic discharge in these cases is considered by Klingenstein. He regards it as indicating the advent of intracystic or intraductal epithelial proliferation. Few surgeons would take the risk of not removing the breast in a case of mastitis complicated by a serous or serohæmorrhagic discharge, spontaneous or induced by gentle massage in the direction of the nipple. The great importance of sending every breast removed for pathological examination, if it were not otherwise recognised as a wise precaution, would be proved by the difficulty in recognising diffuse intraduct carcinoma. The macroscopic similarity between this admittedly rather rare condition and "cystic mastitis" has been sufficiently demonstrated.

THE BIRTH CONTROL MOVEMENT

THE National Birth Control Association, with which the Birth Control Investigation Committee is incorporated, has published this week its fifth annual report, and a history of five years of work offers to the governing body a good opportunity to summarise the past, review the present, and indicate plans for the future. When this Association started in 1930 the Ministry of Health had issued no memoranda defining the powers of local authorities in the matter of giving birth control instruction, and no local authorities had opened clinics although there were 16 voluntary bodies of this description. The staff consisted of the secretary and there were no local branches. To-day the Association has 28 local branches and the staff consists of seven, including three organisers—by no means an extravagant staff considering the amount of ground that is covered. The Ministry of Health has issued 3 memoranda, 66 municipal and 47 voluntary clinics have been established, 42 local authorities send patients to private doctors or clinics, 56 have passed favourable resolutions, while 14 have expressed themselves willing to lend or hire premises to local branches for voluntary clinics. The total expenditure, apart from research, has come to just over £6000 for five years' work.

The present situation indicates that the next five years should show an increasingly rapid development. In 1934 the circular issued by the Ministry of Health elucidated previous provisions and made it clear that the maternity and child welfare authority has the power to give advice at a gynæcological clinic to all women in need of medical counsel. The 56 local authorities mentioned above as having shown a favourable attitude towards the work must be induced to implement their goodwill; but there still remain over 250 child welfare authorities in England and Wales which have taken no action of any sort. The Association possesses evidence that organising work produces quick results, the words of the report being:

"In many a town, an organiser who on her first visit was greeted with suspicion and apprehension so that many of those upon whom she called were afraid to discuss birth control, has at the end of a few months established a branch with a strong committee, influential supporters, and a flourishing clinic."

The public attitude to the work is shown by quotations from the reports of medical officers of health

and from borough councils, one from a Welsh urban district council stating that a comparison with last year's statistics shows that the number of women attending on account of debility, due to too frequent child-bearing, has increased from 18 to 26 per cent. There is also an increase in the number of patients suffering from debility due to miscarriage or abortion.

From the investigation committee, of which Sir Humphry Rolleston is chairman and Dr. C. P. Blacker the honorary secretary, and from the medical subcommittee, of which Dr. Helena Wright is chairman, come also evidence of progress, and, as might be expected, the increased activities call for, while they justify, an increased income. The need, as stated, is remarkably modest; the Association wants, in order to pay its way and meet expansion, at least £1800 per annum, but possesses an income of £1000 only. Its call for further support is amply justified, and the latest record of work done should lead to the necessary increase of members. Subscriptions and donations should be sent to the hon. treasurer, National Birth Control Association, 26, Eccleston-street, London, S.W. 1. The annual subscription of members is £1 1s.

A BIOLOGICAL ASSAY OF LIVER EXTRACTS

MANY attempts have been made to devise a method for biological assay of liver preparations. None has hitherto proved of practical use. It has hitherto been essential to test all material of unknown potency upon patients with Addisonian pernicious anæmia. Such patients should have a red cell count below 2,000,000 per c.mm., and no complicating factors such as sepsis present. Recently however, two promising lines of attack on the problem have been proposed. Miller and Rhoads¹ by feeding swine with a modified form of the diet which produces black tongue in dogs have produced a symptom-complex, not unlike that of pernicious anæmia, which is relieved by the administration of potent liver extracts. These observations suggest that in the future such anæmic swine may be used as test animals. Landsberg and Thompson² and Jacobson³ working independently have shown that the guinea-pig reacts to the administration of potent liver preparations by a reticulocytosis. Jacobson employed adult male pigs weighing between 300-800 g. and kept on a diet of oats, carrots, and lettuce. He found that 30-70 per cent. of the animals showed a significant rise in the number of reticulocytes following parenteral injection of active liver preparations when first given. The uninjected guinea-pigs offer no clue that might seem to differentiate between the two classes of guinea-pigs—i.e., those that will react and those that will not. Further tests of initially non-reactive animals may show them later to have become reactive. Conditions in the guinea-pig necessary for a reaction to occur are not yet clear. Using known reactive animals, it has been possible to show that for every active material there exists a minimal effective dose which is termed the guinea-pig unit of hæmopoietic activity and which is a quantitative expression of the degree of activity. It would appear justifiable to conclude that the capacity to induce a reticulocytosis is confined to materials effective in pernicious anæmia, since, when an assay on guinea-pigs of crude extract from human livers was made, a control healthy human

¹ Miller, D. K., and Rhoads, C. P.: *Jour. Clin. Invest.*, 1935, *xiv.*, 153.

² Landsberg, J. W., and Thompson, M. R.: *Jour. Amer. Pharm. Assoc.*, 1934, *xxiii.*, 964.

³ Jacobson, B. M.: *Jour. Clin. Invest.*, 1935, *xiv.*, 665 and 679.

liver gave a value of 127,000 guinea-pig units, while that of a case of pernicious anæmia in partial remission had a value of 47,000, and that of two cases in relapse had a value of only 650 and 380 guinea-pig units. The material in liver, therefore, which is reticulo-cytogenic in the guinea-pig is at least closely related to the material effective in pernicious anæmia. The administration of the extrinsic factor of Castle alone to guinea-pigs was ineffective, but extrinsic factor predigested with gastric juice was reticulo-cytogenic. Comparative studies of potency of certain materials carried out on guinea-pigs and patients gave results which agreed in a satisfactory manner. The rise in reticulo-cytes considered positive by Jacobson is slight, but from considerable experience he claims that provided a rigorous technique is employed the results obtained are significant and he concludes that regardless of the obscurity of the basis of the phenomenon the guinea-pig test is a valid indicator of the therapeutic efficiency of materials effective in pernicious anæmia.

THE CANADIAN MEDICAL ASSOCIATION¹

THAT the history of medicine is, speaking in general terms, a history of civilisation, is becoming more obvious as more historical reading is placed before us. For numerous books which have been published during the last 20 years tell the story of medical improvements and developments as they are contemporary with the evolution of general politics. The fact that throughout the most troublous times in the story of nations medicine has gone steadily on its way, while dominions and powers disappear or are modified out of their original schemes, contrasts the record of medicine as a continuous one with general history which has been subjected to countless breaks and setbacks. One great example only of this steady progress will suffice—it stares us in the face. The recent European war has seen a complete dissolution of many political systems, while the science of medicine has not only maintained its progress but has benefited in obvious directions by the opportunities given for new work to meet new circumstances. Dr. MacDermot in telling the story of the Canadian Medical Association shows very well that when once the idea of coöperative action has been perceived, the medical spirit will lead to organised action, and that the results of that action will be for the public good, whatever troubles general society as a whole may be going through. The Canadian Medical Association grew from small beginnings and for many years its position was quite precarious. Attempts to organise medicine in Canada were made at least 90 years ago, but for the first 50 years they were abortive, or only useful in affording experience to others who were resolved to carry on the work. At the end of the last century, however, and indeed up to the breaking out of the European war, the Association became representative of the Canadian profession, established a relationship with local and provincial medical societies, and issued a journal which promised to be well established. Then came the war when the systematic work of the Association was sharply curtailed, for its individual members were mostly involved in military duties and a mere skeleton of the organisation remained. It was contrived, however, to keep the journal alive, and three years after the war a strong committee restored the Association to a stable position, so that

to-day, while looking back upon an honourable past a useful future is open to it. Dr. MacDermot supplies an interesting chapter in medical history.

HIGH PROTEIN DIETS IN ALBUMINURIA OF PREGNANCY.

To the devising of diets for the toxæmias of pregnancy there is no end, nor is there likely to be as long as the ætiology of these disorders remains obscure. But while most of the régimes which have been proposed have enjoyed only transient or local vogue, there is a fairly widespread and persistent impression that protein is bad for the potential eclamptic. How this impression has gained credence is not clear, for the idea of eclampsia as a result of rotting of flesh food in an obstructed bowel seems to depend more on vegetarian superstition than on scientific fact. Nevertheless, the superstition dies hard and there is little doubt that protein restriction is widely practised, not only in toxæmia but also in normal pregnancy. There is no convincing evidence that the practice does good, but is it certain that protein restriction is not harmful in pregnancy? After all the full-term uterus and its contents represent a considerable mass of protein which must come either from the mother's diet or from the protein reserves of her own muscles. A recent paper by M. B. Strauss¹ has some bearing on these reflections, for he reports that the protein content of the diet and also the concentration of protein in the blood plasma is consistently lower than normal in cases of pre-eclamptic toxæmia. Moreover, he found that when he treated such patients with diets poor in protein the œdema and albuminuria were aggravated; whereas a high protein diet led to a reduction of the œdema and improvement of the toxæmic symptoms. The significance of these observations is not, as yet, clear, for the improvement in the latter group may have been partly due to simultaneous administration of vitamin B. The number of cases so far treated has also been small and it is well known that simple rest in bed will often cause considerable improvement. It would certainly be unwise to infer that protein starvation is an important cause of toxæmia, for it must be remembered that the incidence of eclampsia was abnormally low in the starving central European countries during the last war. The problem goes deeper than that; but Strauss's paper should at least prompt the obstetrician to ask himself whether he is justified in depriving the pregnant woman of protein.

SYMPATHECTOMY FOR DYSMENORRŒA

THE cause of primary dysmenorrhœa has never been ascertained. On the assumption that it may arise from some disturbance or imbalance of the sympathetic innervation of the uterus, interruption of the sympathetic supply has of recent years been advocated and practised with considerable success. Of the several methods which have been devised that of Cotte (resection of the superior hypogastric plexus) seems to be the most satisfactory. V. S. Counsellor and W. McK. Craig² have reported 14 cases from the Mayo Clinic, of which it is stated that 9 obtained 100 per cent., 2 obtained 95 per cent., and 3 obtained 75 per cent. relief; there were no deaths and no serious complications. A discussion held by the section of obstetrics and gynaecology of the Royal Society of Medicine³ two years ago

¹History of the Canadian Medical Association, 1867-1921. By H. E. MacDermot, M.D., F.R.C.S. (C.). Toronto: Murray Printing Co., Ltd. 1935. Pp. 209.

²Amer. Jour. Med. Sci., December, 1935, p. 811.

³Amer. Jour. Obst. and Gyn., 1934, xxviii., 161.

³Proc. Roy. Soc. Med., 1934, xxvii., 258.

produced a number of case-reports by different surgeons: Mr. A. A. Davis gave his percentage of one-year cures as 50; Mr. Malcolm Donaldson reported 16 cases, of which only 1 failed to obtain relief; of 8 cases reported by Mr. Sidney Forsdike 2 were completely, and 5 partially, relieved, while 1 derived no benefit at all. The last-named speaker emphasised the necessity for care in the selection of cases for operation, pointing out that the comparative ease and safety of the procedure renders it liable to abuse. F. S. Wetherell,⁴ who has had several successful cases, also utters a warning against too ready resort to what is in effect a major abdominal operation accompanied by distinct risks. F. E. Keene⁵ lays stress on the occasional anatomical difficulties and added dangers; the inferior mesenteric vessels, for example, may be situated further to the right than is usual, so that dissection of the nerve plexus from beneath them may be very difficult and fraught with danger to the vessels.

In a paper which we publish this week, Mr. Davis describes 6 cases treated by alcohol injection of the pelvic plexuses in the neighbourhood of the uterus. This method, first used by Blos, has the great advantage over sympathectomy that it is a comparatively minor procedure and does not carry the risks inseparable from laparotomy. The chief drawback seems to be that it does not allow of possible gynaecological lesions being discovered and treated, and these cannot always be excluded, especially in stout women, without operation.

URETERO-INTESTINAL ANASTOMOSIS

A CONDITION which calls for uretero-intestinal implantation is serious enough, without the added inconvenience to the patient resulting from leakage or an ascending infection. Every method so far devised of forming a uretero-intestinal anastomosis has its inherent disadvantages and none is suitable for every case. Some of the methods advocated have resulted in a high percentage of failures, no matter how skilfully the operation has been performed. Others, whilst theoretically sound, are attended by such technical difficulties that only a surgeon with a large experience of this type of work can overcome them. In the December number of *Surgery, Gynecology, and Obstetrics* Dr. Frank Hinman describes a method of implantation in many ways simpler than those advocated by Coffey and no more liable to subject the patient to the risk of complications such as ascending pyelonephritis, compression of the ureters, or leakage of urine or faecal material at the site of implantation. Hinman's method also has the advantage of allowing both ureters to be transplanted simultaneously; it dispenses with the use of ureteric catheters or fine rubber tubes. Pre-operative treatment involves a non-residue diet for at least three days and the clearing of the bowel by castor oil and repeated enemata as well as the use of urinary antiseptics.

The operation consists essentially in the formation of peritoneal flaps and the isolation of the ureters. The peritoneum is slit alongside that portion of the pelvic colon into which the ureter is to be implanted. The outer flap of peritoneum is then stripped up, the ureter found, and held by passing under it a rubber tape. By traction on this tape, the juxta-vesical portion of the ureter is made visible under the peritoneum and a small incision allows it to be reached and divided between ligatures close to the bladder. Convenient sites for

implantation are then selected, preferably not at the same level and marked on the bowel by stay sutures at either end of the imaginary incision. The ureters are then implanted with seven sutures. The method of doing this is to make a clean cut from 2.5 to 3 cm. long in line with the stay sutures, over the muscular coats which are teased back to expose the surface of the mucosa. The sutures are inserted by means of an atraumatic needle passed through the submucosa of the bowel, and through the adventitia of the outer side of the ureter avoiding both lumina. Dr. Hinman gives explicit details, clearly illustrated, concerning the method of inserting these sutures so as to avoid constricting the ureter, and to ensure a good fit. Flaps of peritoneum are then adjusted so as to cover the lines of sutures, care being taken that neither bowel nor ureter is pulled out of line by these flaps, and the abdomen is closed in layers without drainage.

Dr. Hinman reports that 12 patients have undergone simultaneous bilateral implantation by this method; 5 have died, but only 1 of these deaths is directly the result of the operation (bronchopneumonia). Three of the deaths followed an attempt to remove radically at a second operation the bladder, prostate, and vesicles for carcinoma. In none of the 12 patients was there any urinary or faecal leakage at the site of implantation.

ASCHOFF'S SEVENTIETH BIRTHDAY

SOME eighteen months ago British pathologists took the opportunity of his seventieth birthday to pay a tribute to the doyen of their science in this country, Sir Robert Muir. To-day, Jan. 10th, they join with their German colleagues in celebrating the seventieth birthday of Prof. Ludwig Aschoff. For the last 30 years his institute at Freiburg has been the mecca of young men from all countries who have sought inspiration and guidance in methods of pathological research; and none has come away empty-handed. Aschoff's last visit to England was in the summer of 1932, on the occasion of the centenary meeting of the B.M.A. The section of pathology was being addressed by one of his former disciples when the door opened to admit a late-comer whose agitated progress to a seat was somewhat impeded by an overcoat, suitcase, and umbrella. A gleam of delighted recognition was followed by an exchange of solemn bows before the discourse was resumed. On the next day the visitor himself delivered a remarkable address, and was subsequently entertained to lunch by a joyous assemblage of friends and admirers of all ages. Aschoff is a great master of morbid anatomy; there is scarcely a branch of the subject which he has not illumined by his knowledge and enthusiasm. At the age of 70 he retains that living interest in pathology which has proved a stimulus to generations of his students. To hear Aschoff lecture, to see that frail form quivering with the eagerness of exposition, is an experience never to be forgotten. One is reminded of a racing speed-boat, throbbing with the power that shakes the whole craft into impetuous motion. Such men have little to fear from the encroachment of the years.

Mr. F. D. Donovan, surgeon-dentist to H.M. Household, was created a Commander of the Royal Victorian Order in the New Year honours list.

THE tenth British Congress of Obstetrics and Gynaecology will be held at Belfast from April 1st to 3rd under the presidency of Prof. R. J. Johnstone. Details are given on p. 124.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXIV.

PROGNOSIS IN CHRONIC BRONCHITIS AND EMPHYSEMA

IN chronic and slowly progressive conditions prognosis is often as much concerned with the outlook in regard to economic capacity and outdoor activities as with the probable length of life. This is particularly true in patients suffering from chronic and recurrent infections of the air-passages and in those with emphysema, the more so since the patients are usually in the middle and later periods of life when business and family responsibilities are serious. In these conditions prognosis is therefore an important practical problem and demands most careful consideration of a number of factors, to each of which due weight must be given. It is convenient here to consider and discuss these in a definite order, such as would be adopted in the assessment of a particular case.

Family history.—There can be little doubt that a tendency to emphysema may be inherited. It is sometimes found comparatively early in life in the absence of any cause of chronic expiratory stress. In such cases a family history, in parents or collaterals, of chronic bronchial conditions and of early death from respiratory diseases or cardiac failure may be of significance. Cohnheim went so far as to suggest a congenital defect in the elastic tissue of the lung as a factor in the genesis of emphysema. Osler, writing of arterio-sclerosis, referred to "vital rubber," and suggested that in early family incidence of that condition, it could not be explained "in any other way than that in the make-up of the machine bad material was used for the tubing." It is also generally recognised that elastic tissues tend to deteriorate with advancing years.

Personal history may be of the greatest significance in prognosis. The age at which the yearly winter cough started, the number of years during which it has occurred, and the length of the summer intermission, are all of importance. It is usually found that this intermission becomes progressively shorter and its reduction in length is in some degree a measure of the progress of the condition, and therefore of prognosis. In this connexion Kingston Fowler pointed out that the abrupt cessation of the summer intermission, in other words, the persistence of the cough through the summer months in cases where there had previously been some weeks or months of freedom, should always arouse a suspicion of the presence of tuberculosis, and this I have often verified. Since emphysema tends to mask the signs of early tuberculosis this is an important observation, and indeed in the past many cases of tuberculosis in elderly people have masqueraded as chronic bronchitis and emphysema, and have been responsible for widespread family infection. The recognition of its presence may lead to a more serious prognosis in such patients than the previous history would suggest.

Respiratory diseases in early life leading to chronic cough or to fibrosis with bronchial dilatation, either fusiform or sacular, are important factors in leading to chronic expiratory strain and thus inducing widespread emphysema. They certainly must be considered as unfavourably influencing the prognosis in regard to the full expectation of life and in regard

to full economic activity in middle life. In the future it is to be hoped that more attention may be given to convalescence after such conditions, and to special measures such as breathing exercises to obviate or mitigate their after-effects.

Long-continued asthma, especially when associated with bronchial infections, leads to increasing emphysema, and therefore may influence prognosis unfavourably, though spasmodic or allergic asthma, being often intermittent, is less serious in this regard. Coexisting renal or cardiac disease and conditions such as diabetes, obviously tend to render prognosis more serious.

Occupation, habits, and habitation.—Occupations involving exposure to inclement weather, to dust, and to risks of infection are unfavourable, as also are those involving heavy muscular strain or prolonged exertion. Blowing wind instruments has long had a bad reputation in this regard, but it may be questioned if it is altogether deserved, especially if adequate training in breathing and blowing has been given.

Habits are also of some significance in prognosis. Over-smoking, especially the inhaling of cigarette smoke, tends to produce chronic cough and hawking, and patients should be warned of its ill-effects. Alcoholic over-indulgence is also unfavourable by promoting infection, and leading to earlier cardiac breakdown. Habitation is also of great importance, particularly at times other than the summer. Patients with chronic bronchitis and advancing emphysema are most comfortable in dry, warm climates, especially in places where high atmospheric pressures are common. Cold, damp localities are unfavourable, and predispose to further catarrhal manifestations. High altitudes and rarefied atmospheres tend to induce dyspnoea in advanced cases and are contra-indicated.

Social state is a factor of great importance in prognosis. Those in comfortable or affluent circumstances can avoid unfavourable winter conditions by migrating to sheltered areas in this country, such as the south and west coasts of England, and certain parts of the Welsh coast, or to resorts in Egypt, North Africa, the Mediterranean, the West Indies, California, South Africa, or the antipodes. Even those less favourably circumstanced may do much to protect themselves by remaining indoors in damp, foggy, and windy weather, though in older people this may involve weeks or even months without outdoor exercise. Such precautions are clearly impossible for the vast majority of those, both men and women, who have to earn their living by work away from home. In the large industrial towns in this country the daily journey to and from work, with the incidental risks of exposure, infection, chill, and wetting, gravely affects the prognosis in workers who develop chronic bronchitis and emphysema, and the problems offered to medical men in treating and advising precautions in these conditions are difficult in the extreme from the absolute inability of many such patients to follow the advice given.

Symptoms and physical signs.—Symptoms often afford valuable information in regard to prognosis, particularly cyanosis, dyspnoea, and cough. Cyanosis is to some extent a measure of the degree of emphysema and of the extent of the stress on the right

heart resulting from it, though it is in part due to the incomplete oxygen saturation of the blood and the resultant polycythæmia. It should, however, be remembered that patients with this condition may show an extreme degree of cyanosis and yet be able to walk about and work. When the cyanosis is associated with secondary heart failure and œdema its prognostic significance becomes greater and more serious.

Dyspnœa apart from intercurrent acute bronchitis is a serious indication and suggests advanced emphysema or increasing circulatory failure. This may be evidenced not only by effort but also by the number of pillows used by the patient at night. Spasmodic dyspnœa of asthmatic type is common and is often induced or aggravated by intercurrent acute or subacute bronchial infections. Its prognostic significance is difficult to determine. If it is long continued, it is of serious import, both by increasing the emphysema and by promoting circulatory stress.

Cough is often troublesome and serious for similar reasons. It may also cause disturbed nights and so react unfavourably. It sometimes happens that a violent paroxysmal cough develops in which the patient becomes deeply cyanosed, and may even become momentarily unconscious. This is usually an unfavourable prognostic indication. Expectoration varies from little or none to copious amounts of frothy fluid or of tenacious muco-pus. In the latter case it suggests some degree of bronchial dilatation and is an unfavourable sign. Hæmoptysis is rare and should excite suspicion of latent tuberculosis, or "silent" bronchiectasis.

The physical signs are perhaps less significant in regard to prognosis than the symptoms; indeed, Cabot has raised a doubt as to the characteristic barrel-shaped chest being diagnostic of, or the result of emphysema. In any case, the rigid chest of this type in pronounced degree, associated with marked extension of the resonance or hyper-resonance beyond normal limits, obliterating or diminishing the areas of cardiac and liver dullness, connotes considerable diminution of respiratory efficiency, but is less significant in relation to prognosis than signs of right ventricle engorgement or failure. Evidence of tricuspid regurgitation is usually a serious portent. Persistent rhonchi, especially of the sibilant type, particularly when associated with constant bubbling râles at the bases of the lungs, are unfavourable, indicating chronic inflammation of the smaller tubes. Fine râles on deep inspiration heard near the sternum or in the axillæ are frequent in mild cases and of less significance.

Small-lunged emphysema is usually a senile, atrophic, or degenerative process and is associated with less dramatic symptoms until cardiac failure supervenes.

X ray appearances in large lunged cases are somewhat characteristic, showing the increased extent and trans-radiancy of the lung tissues as well as the degree of cardiac enlargement, and these may give some indication of the degree of the condition.

Special tests.—Estimations of the vital capacity may give useful information. This may be very considerably reduced, and a diminution approaching half of the normal should be regarded as serious. Other tests, such as the manometer test, Flack's endurance test, and those devised by Moncrieff are not yet in general use, but can be employed in special cases. Effort response tests and electrocardiographic investigation may also give useful indications,

especially in regard to the degree of circulatory impairment resulting.

Complications and intercurrent diseases.—Chronic renal disease, organic heart disease, raised blood pressure, diabetes, asthma, and pulmonary tuberculosis all affect prognosis in chronic bronchitis and emphysema adversely, while the risks of intercurrent febrile conditions such as influenza or pneumonia are gravely increased.

Treatment.—The results of treatment, especially that designed to prophylaxis of bronchial infections, are of great importance in regard to prognosis. Inoculations with vaccines, either autogenous or stock, may in some cases help greatly in mitigating or even preventing the winter cough. Even one free winter secured by this means or by an escape to more favourable conditions for the winter months in some resorts like those already mentioned may serve to arrest or to delay the advance of the emphysema. Treatment by compressed air baths at a pressure of $1\frac{1}{2}$ atmospheres is often helpful, especially in cases complicated by bronchial asthma. The special respiratory treatments afforded at certain spas, notably La Bourboule, Mont Dore, Reichenhall, and Ems, can also be helpful in lessening the catarrh of the air-passages, relieving asthmatic spasm, and possibly in increasing resistance to infection. It is to be hoped that in the future similar methods may be tried systematically at some of the British spas.

SUMMARY

Chronic bronchitis and emphysema are not in themselves fatal conditions, or indeed even direct causes of death, though they may, either alone or in association, be the means of shortening life, by leading to earlier respiratory and cardiac breakdown, or by rendering more grave the struggle in serious intercurrent disease such as influenza, pneumonia, or pleurisy.

It is difficult to assess the prospects of a particular patient on the lines of the numerical method now used in life assurance offices, especially in America. In this method, numerical debits are given for unfavourable factors such as heredity, unsuitable occupation, bad habits, and progressive physical signs, while credits are given for favourable indications such as social state, comfortable conditions of life, and habitat. A careful assessment on these lines of all the factors considered above might enable some useful conclusions to be formed in a particular case. In general terms, a young patient with hereditary tendencies and with a personal history of respiratory disease early in life leaving persistent lesions and signs is likely to be economically damaged in or before the fourth decade of life, more especially if the conditions of living and work are bad. Such a patient would certainly be rated up for life assurance either by the addition of several years to the age or by the limitation of the assurance to an endowment at 50 years of age, and even then probably with an extra. On the other hand, a patient who does not develop bronchitic tendencies until the middle or late forties, who is comfortably circumstanced, whose work does not involve exposure or unfavourable conditions, and whose symptoms and physical signs are only slowly progressive, may well live nearly the normal span and be enabled to work to the age of 60 or after; but even such a case would probably be rated up for life assurance.

SPECIAL ARTICLES

THE CONTROL OF MEASLES *

By J. A. H. BRINCKER, M.B. Camb., D.P.H., F.I.C.

A PRINCIPAL MEDICAL OFFICER OF THE PUBLIC HEALTH
DEPARTMENT, LONDON COUNTY COUNCIL

MEASLES has no doubt been with us always. It is a disease usually affecting children and occurring in London in epidemic form biennially from autumn to spring, though it has been known to appear epidemically in hot months and to affect adults severely. In temperate climates and in city populations it reappears with almost clock-like regularity biennially at the end of October. It crops up in one or more separate places and gathers momentum until it reaches epidemic proportions in January and February, after which it subsides. By the end of June it has more or less disappeared, not to reappear in epidemic form until the following October twelvemonth.

EPIDEMIOLOGICAL FEATURES

Measles is a disease which fulfils with remarkable accuracy the conditions of an epidemic cycle (Fig. 1); its waves of prevalence, with their respective rises and falls, are interspersed with periods of absence. A disease affecting a large human community, it has interested many epidemiologists, for it provides admirable material for the detailed study of an epidemic. In London it began to assume special prominence in 1900, and a medical officer was appointed to deal with the health of the London school population. The picture it presented at that time was of a severe epidemic descending on a large school population, affecting within six months some 35,000 to 40,000 children, killing a large proportion of them and maiming more, causing the absence from school of those affected and of their brothers and sisters, necessitating frequent school closure for indefinite periods during the epidemic and paralysing the educational machinery. At that time little was known about the behaviour of epidemics generally and the precautions to be taken to deal with them. Such measures as were adopted were invariably of a panic nature and were always undertaken too late; it was the usual tale of closing the stable door after the horse was out. It was not even suspected that the elder children, infected in school, were, on the closing of the schools, being sent home to infect their younger brothers and sisters who were not attending school. It was assumed that all children would sooner or later contract the disease and that they would have to take their chance of recovery or death. Treatment of patients by attention to general hygiene methods and by the provision of home nursing, or removing them to hospital to prevent complications, was not thought of and children affected were only admitted to the wards of poor-law hospitals when they were dangerously ill.

The study of the epidemiology of measles in London commenced, then, in 1900, chiefly with the observation of school-children and the keeping of statistical records relating to schools. The chief aim in dealing with an epidemic was to stop it or at any rate slow it down. Various measures were adopted with this end in view, such as complete closure of schools, closure of infant departments or of classes in infant departments attended by the younger children, and exclusion of children who had not previously suffered

from the disease, either for the whole period of the epidemic or for the period during which they would be likely to contract the disease—i.e., from the ninth to the sixteenth day after exposure. Complicated rules were drawn up and were faithfully carried out by school teachers, school nurses, and attendance officers, and much praise is due to them for their coöperation in the attempts made to deal with these epidemics.

These precautions, with variations, were carried out during every succeeding epidemic, but they proved futile and were finally given up in 1918. Though these experiments were a failure so far as controlling

Epidemic Cycle of Measles

FIG. 1.—Chart showing the number of admissions for measles to L.C.C. fever hospitals (plain area) and inoculations of adult serum (black area) for each week from Nov. 1st to August 31st during the epidemic periods 1931-32 and 1933-34.

the spread of the disease was concerned they taught us many things about the behaviour of an epidemic of measles which are now generally accepted. For instance, in addition to those characteristics already mentioned, it was observed that:—

1. A measles epidemic did not arise in a community of children until the susceptibles rose to 25 per cent. and the epidemic did not stop until this susceptible population was reduced to under 20 per cent.
2. Epidemics when they started did not flare up at once, but required both time, inflammable material, and the right weather conditions to gather momentum.
3. In London, at any rate, measles was a disease affecting children under 7 years of age, and therefore boys and girls in the upper classes of schools were of no account in the spread of the disease.
4. Contacts only became active in spreading the disease from the time the coryzal symptoms developed and the risk of transmitting infection diminished rapidly after the disappearance of the rash; in fact, the greatest risk of communicating infection occurred in the pre-eruptive stage, from the ninth to the twelfth day of incubation.
5. The disease itself did not kill, but predisposed the patient to the great risk of secondary infection by hæmolytic streptococci (resulting in deadly complications such as broncho-pneumonia) and to others such as otitis media and ophthalmia, which, while not so deadly in themselves, could give rise to life-long disability.

* A paper read to the Hunterian Society on Dec. 16th, 1935.

6. The most susceptible age, both for measles and complications, was the pre-school age and by far the greatest number of deaths occurred in the second and third years of life.

P. Stocks later pointed out that the old belief that all children were bound to suffer from measles was not correct.¹ For every 100 children suffering from a clinical attack of measles in a densely populated area about 300 others become temporarily immunised, presumably by subliminal doses of the virus, but of these 300 some 250 lose their immunity again before the next epidemic. It is these children who have lost their immunity, together with those born subsequent to the epidemic, who make up the vulnerable population ready to start the next epidemic.

FAILURE OF QUARANTINE

By 1918 sufficient knowledge had accumulated to demonstrate the necessity of attacking measles by other means. First and foremost it was clear that quarantine, on which so much faith had been placed in the past, and which had been found wanting, was based on erroneous ideas. It was therefore necessary to abandon it finally and completely. As already stated, it was established that measles was particularly dangerous to the pre-school child and the success which attended the experiment of dealing with cases at home on open-air lines and by hygienic methods showed the need for home nursing and medical assistance. These were provided by empowering the borough medical officer of health to call in such aid. By the Maternity and Child Welfare Act of 1918 local health authorities were not only able to provide medical and nursing aid, but also, through the establishment of child welfare clinics, to educate the mother in matters of health and hygiene. In 1910 measles began to be admitted to the fever hospitals of the late Metropolitan Asylums

Increasing Hospitalisation of Measles in London

FIG. 2.—Chart showing the total admissions for measles to London fever hospitals (M.A.B. and L.C.C.) from 1924 to the present time.

measles to the wards of the fever hospitals *pari passu* with scarlet fever, the criteria for admission being the type of home and the facilities therein for the proper care of the patient, rather than type of case. To these criteria was subsequently added the age of the patients, in view of the high mortality amongst children under the age of 2. At each of the subsequent epidemics of measles more and more cases were admitted to the fever hospitals (Fig. 2). In the 1931–32 epidemic 11,368 cases were admitted

during the 10 epidemic months and in the 1933–34 epidemic 10 months 12,730 cases, selected in this way, were treated in the wards of the L.C.C. hospitals. By this means many lives were saved, as the case-mortality demonstrates, for of admitted cases in successive epidemics this was 7, 6.5, 5.3, and 5.1 per cent. respectively. It may be of interest to note that patients are treated to a considerable extent in open wards and that under such conditions even cases of severe broncho-pneumonia, otherwise considered hopeless, are nursed back to health.

It is obvious that hospitalisation provides for large numbers of children treatment such as it would be impossible for them to receive at home. In addition to being skilfully nursed in bed in well-ventilated wards with plenty of fresh air, and provided with suitable diet and medical treatment, many accessory lines of treatment are available. Thus many patients are now treated with antistreptococcal serum in the hope of preventing complications. The oxygen tent has been found of great value in dealing with broncho-pneumonia and, in cases of empyema, success has attended the use of the Drinker apparatus to prevent permanent collapse and fibrotic changes in the lung. Skiagrams are now considered necessary for the treatment of the after-effects of measles.

SERUM PROPHYLAXIS

Once measles has been contracted serum is of no use; the aim is either to prevent or to attenuate the disease in those exposed to it. It must therefore be used during the period of incubation. The first attempt to modify measles was made by L. Weissbecker 40 years ago. He employed convalescent measles serum in the early stages of the disease. The first published report on the procedure was made by Nicolle and Conseil in 1918. Since then Degkwitz (1920) and other workers have used convalescent serum to modify the disease. Until the 1929–30 epidemic in London little or no attempt had been made to control the disease by the prophylactic use of immune sera. It is true that in America and Germany attempts had been made to procure immune sera from animals, but all these proved valueless or unreliable and their use was ultimately abandoned. Among such sera were those prepared by Tunncliffe, Ferry and Fisher and Degkwitz. Before the 1929 experiments a few pioneers were at work, the most conspicuous among them being Dr. E. H. R. Harries, then in Birmingham, Dr. D. N. Nabarro at Great Ormond-street Hospital, and Dr. W. Gunn at the Park Hospital. They used serum prepared from the blood of persons who had recently recovered from an attack of measles. During the 1929–30 epidemic in London, however, convalescent measles serum obtained from the blood of such persons was tried on a large scale. This serum proved very efficacious both in preventing an attack and in attenuating the disease. Whether the one or the other was attained depended on the dose of serum given and the time at which it was administered. The varying effect of dosage and the day of injection was very carefully observed and from the experience thus gained any desired result could be attained. Convalescent measles serum thus proved of great value, particularly in preventing children already seriously ill with some other complaint or those about to undergo an operation from contracting the disease after a known exposure. Its use also obviated the need of placing a children's ward in quarantine on the occurrence therein of a case of measles.

Unfortunately most of the patients suffering from

¹ THE LANCET, 1930, i., 796.

FIG. 3.—Synoptic chart showing the typical course of measles: (1) uncomplicated, (2) with the two commonest complications, (3) attenuated by immune serum (a) to the desirable degree and (b) to an undesirable degree with an attack too mild to confer lasting immunity. The dosage of serum and the time-table of its administration are as follows:—

Nature of serum.	Dose in c.cm.	Dosage factor.	Route.	Prophylaxis.		Treatment.
				Protection.	Attenuation.	
Convalescent ..	5-20.	Age × 2.	Intramuscular.	1st-5th day.	5th-9th day.	} Within 6 days of onset. Dosage factor : age × 4. Route : intravenous.
Normal adult ..	10-40.	Age × 4.	Intramuscular.	1st-3rd day.	3rd-9th day.	
Whole blood ..	Double its serum.	Age × 4.	Intramuscular.	1st-3rd day.	3rd-9th day.	

measles are very young children from whom blood cannot well be abstracted and the number of adults suffering from the disease is so small that the amount of convalescent measles serum available in any epidemic must be very limited. Moreover, to be of value an immune serum should be available at the commencement of an epidemic and not towards its end. Chiefly for these reasons other sources of antibodies had to be sought. It is well known that an attack of measles produces a permanent immunity and that, in London at any rate, most adults have either suffered from measles in childhood or are immune. It was, therefore, suggested that serum obtained from young healthy adults might have some immunising property. To determine if this were so serum was obtained from healthy adults who had volunteered to give it and tested in the same way as convalescent measles serum. This serum is referred to as adult measles serum to distinguish it from the convalescent measles serum obtained from those recently recovered from measles.

I will now summarise the experience which followed the use of this serum culled from an account of the 1931-32 London epidemic. The type of children in whom complete protection is advisable are those who are weakly or debilitated; those suffering from any serious intercurrent disease, infectious or otherwise; and all children under 3 years of age, whatever their condition. For these a minimum dose of 10 c.cm. adult measles serum is recommended. From the age of 3 years onwards the dose is reckoned in cubic centimetres by multiplying the age in years by four. To ensure protection, the serum should be administered within five days of the earliest known exposure to infection; the earlier the injection is made, the more likely is complete protection to follow. The injections should be given intramuscularly, preferably into the vastus externus. The duration of the immunity conferred is roughly three to four weeks.

After the age of 3 years, provided that the physical state is satisfactory, it is desirable to aim not at complete protection but at a modification of the attack of measles if circumstances permit. This is achieved by injecting the serum, in the doses already recommended, later in the incubation period—viz., from the sixth to the ninth day after exposure. The same results may be attained, with resulting economy in serum, by halving the dose and giving the injection within the first five days. The immunity which follows a modified attack appears to be permanent. Of course, if the patient has had measles previously the administration of serum is unnecessary and in fact wasteful.

The statistical analysis of the clinical data in the 1931-32 epidemic makes interesting reading. I will assume that if a susceptible child exposed to measles is given intramuscularly a sufficient dose of this serum within five days of exposure he will be protected, and that, if the same dose is given between the sixth and ninth day of exposure, or half the usual dose within the first five days, the child will suffer from a modified attack of the disease. From the data available it would appear that of every 100 children exposed to risk and not given serum 75 will take measles, whereas of every 100 children given serum less than 14 will fall ill, and that four out of every five attacks of measles would be averted or postponed by the administration of serum.

When we come to deal with the efficacy of adult serum as compared with convalescent measles serum the data must be submitted to careful statistical analysis. To quote from Dr. Gunn's report²:—

"In an ideal scientific test of a prophylactic method one would use the method in alternate cases, e.g., in every school or hospital every other inmate exposed to risk would be given a dose of serum. In such circumstances,

² L.C.C. Report on the 1931-32 Measles Epidemic. London: P. S. King and Son, Ltd. 1933. No. 2996. 2s. 6d.

the protected and unprotected are strictly comparable and simple comparison of results, institution by institution, must give an answer to the question proposed—viz., Does the method of protection in fact protect? Administratively, no such plan could be carried out. We must, therefore, fall back upon the less satisfactory method of using, as controls of the prophylaxis, such unprotected children as, for various reasons, become available."

The conclusions arrived at in the statistical examination of the use of adult serum in the 1931-32 epidemic were as follows:

The total number of observations recorded was 2362. The adult serum series, consisting of 1475 observations, was divided into two groups: the first in which complete protection was desired consisted of 1133 cases, and the second in which attenuation was desired numbered 342 cases. The results of 680 injections of convalescent serum and observations on 207 uninjected contacts during the same epidemic period were utilised to form the control series.

The clinical results of the administration of convalescent and adult serum were compared; the figures were standardised to make allowance for variations in the age-distributions. The analysis showed that convalescent serum is a more potent prophylactic agent than the adult serum for each age-group, but that the difference between them is of statistical significance only in respect of children under 5 years of age. The difference is greatest in the 1-3 years age-group, at which period susceptibility is at its highest. After the age of 5 years there is nothing to choose between the two sera, and after the age of 10 years the effect of either serum on the issue is negligible; at any rate as far as the London school-child is concerned.

When the results with convalescent serum in the infectious diseases hospitals are compared with those of adult serum (similar age-distribution and probability of effective exposure) the significant difference favouring convalescent serum is limited to children under 3 years of age. The difference favouring convalescent serum remains true only in respect of injections given on or before the third day after contact. The attenuating results following one-half the standard dose given before the sixth day are as good as those after the full dose given on or after the sixth day.

Finally, the analysis showed conclusively that adult serum is a valuable measure in measles prophylaxis. In its protective and attenuating action, it is only slightly inferior to convalescent serum and merits a high place in any future policy of measles control.

In the 1931-32 epidemic 24,085 c.cm. of adult serum, roughly 2408 doses, were collected by the medical staff of the L.C.C. and in the 1933-34 epidemic 27,335 c.cm., roughly 2733 doses. These amounts were of course far too small to allow work to be done on an adequate scale. Up to the present, voluntary donors, usually the nursing staff in the L.C.C. hospitals and medical students, have been relied on for blood for the preparation of adult serum. The Council has, however, just given authority for an appeal to be made for donors generally, and has agreed to pay each of them 5s. for providing their blood. In a healthy young adult 250 c.cm. of blood can easily be withdrawn and this provides about half its bulk in serum. By this means it is hoped to obtain sufficient material to carry out the effective control of measles during the current epidemic.

If attenuation can be carried out on a large scale in residential and day schools, measles instead of producing havoc in deaths or physical impairment and causing dislocation of school organisation will definitely be under control. Imagine what a boon this will be to medical officers in public schools where measles, although occurring in older boys and girls, produces considerable dislocation of school attendance. Alternatively, in the case of delicate or sick children in hospitals, or those about to undergo operations,

prevention will result in removal of the risks associated with the disease in those least able to stand up to it. Prevention may also be aimed at in the wards of hospitals to avoid placing them in quarantine after a case of measles has occurred.

Fig. 3 gives in concise form typical temperature charts of cases of measles, uncomplicated and complicated, and of children exposed to measles where serum is used to obtain either complete immunity or attenuation. The temperature may be taken to show the reaction of the body to the poison and is therefore an index of the amount of the poison in the child's circulation. The chart also shows what happens to the child from the date of infection until convalescence is established, along with the doses of serum and the dates on which it is to be given in order to modify the disease.

PLACENTAL EXTRACT

It is well known that infants under 9 months old are generally immune to the common infectious diseases. This immunity is ascribed to their obtaining the antibodies from their mothers. If this assumption is correct these immune bodies must be supplied to the child through the mother's placenta. As a practical outcome of this theory placental extracts have been employed to produce protection or attenuation. In placentas it is apparently the globulin which contains these immune bodies. Globulins have been abstracted from placentas and submitted to test. It has been shown, for instance, that such globulin contains 5 units of diphtheria antitoxin per c.cm. and that, tested by the Schultz-Charlton reaction, it contains quite an appreciable amount of scarlatinal antitoxin. There is no means of testing such globulin for the presence of measles antibodies except by the direct method of using it with a view to the prevention of the disease in contacts. This has been done in some cases with promising results. The substance is called immune globulin. It is being prepared in sufficient quantities in the L.C.C. laboratories to be tried side by side with convalescent and adult human serum and it is hoped to accumulate sufficient data by the end of the coming epidemic to say whether, like adult serum, it can play a part in the control of measles. Various preparations of human immune globulin have been tried in America and a full account of the trial has been given.³

Two commercial preparations of placental extract—i.e., of human immune globulin—are now available; they are (1) Placimmudin prepared by E. R. Squibb and Son, and (2) immune globulin (human) prepared by Lederle. These two products have been submitted to the Council on Pharmacy and Chemistry of the U.S.A. They withheld comment on Squibb's product on the ground that the data supplied were insufficient, but they reported as follows on Lederle's preparation.

1. The product is as efficacious for prevention as convalescent serum.
2. The clinical results show sufficient evidence to warrant the doses recommended for prevention. On the available evidence those for attenuation are questionable.
3. Although it is a promising immunising agent more evidence of its value is needed before it is recommended for general use.

We are hoping to test this preparation in London during the present epidemic.

However inadequate and incomplete this account of the past, present, and possible future of measles may be, I hope I have shown that the older methods

³ Jour. Amer. Med. Assoc., 1935, cv., 493.

of control have failed and that, by means of passive immunisation by serum or placental extracts, we have entered on a promising stage in the battle against measles. Much work on the epidemiology of the disease remains to be done, and those of us to whom the control of infectious diseases in hospitals, schools, and homes is entrusted are fully alive to the need for constant experiment.

I am indebted to Dr. W. Gunn for the loan of the three charts on which the figures are based.

MEDICINE AND THE LAW

Medical Supervision of Special Treatment Establishment

THE London County Council has, by Local Act, statutory powers of licensing massage and special treatment establishments. Under these powers a licence was granted to Mr. Alexander Barthels, of Weymouth House, Hallam-street, with a condition that he should not give ultra-violet ray treatment without the supervision of a medical practitioner. An inspector of the L.C.C. found that the condition was being broken and Mr. Barthels was summoned at Marlborough-street police-court last week. The inspector's evidence was that a patient who was undergoing such treatment was asked if she had seen a doctor and if a doctor had recommended the treatment. The patient answered that she had been to many doctors and had received no benefit and had therefore decided to try Mr. Barthels. There was no question of Mr. Barthels's competence. His legal representative was prepared to elaborate the defendant's skill, but the magistrate observed that his competence was irrelevant. The summons was dismissed under the Probation of Offenders Act on payment of £5 5s. costs to the L.C.C. and on the defendant undertaking not to commit a further breach of his licence. The licensee could hardly contend that he was unaware of the restrictive condition. Deliberate violation of the condition is hardly the proper method of appealing against it.

Fraudulent Conversion by Hospital Secretary

Offences between January and October last year formed the subject of charges at West Sussex Quarter Sessions last week against Major W. I. Rogers, former secretary of the Bognor Regis War Memorial Hospital. He pleaded guilty to various charges of fraudulent conversion, intent to defraud, and omission to make entries as to orders of stamps. It was urged in mitigation of sentence that the accused had formerly borne an exemplary character and had received inadequate pay. The chairman of the bench, Mr. Roland Burrows, K.C., observed that judges had from time to time commented on the fact that it was only persons with an exemplary character who obtained posts where they could commit offences of this kind. Passing sentence of 12 months' imprisonment in the second division, he expressed the view that the checking of the hospital accounts appeared to have been lamentably lax, and that, with better supervision, the defendant would not have found himself in his present position.

Unfitness to Plead

A careful paper on "unfitness to plead," read last year by Dr. W. Davies Higson, medical officer of Liverpool Prison, before the annual conference of prison medical officers, is published in the *Journal of*

Mental Science (1935, cxxxi., 822). He points out that this preliminary question of fitness to plead in criminal proceedings is one with which prison doctors may often have to deal. It is common experience, indeed, that judges pay special respect to their evidence. It might be added that the Atkin Committee on Insanity and Crime stressed the importance of medical officers of prisons having special knowledge of mental disorder. As has sometimes been pointed out, the courts examine a prisoner's fitness to plead more carefully in serious charges like murder than in merely trivial offences, and, on the whole, the proportion of prisoners found unfit to plead is advancing.

The Atkin committee advised that a man should not be found unfit to plead except on the evidence of two doctors at least; one of these would usually be the medical officer of the prison. The committee recommended the retention of the procedure. Mental disorder is sometimes so obvious that trial would be a farce; on the other hand, where there is any element of doubt, it is a strong step to put a man away as a criminal lunatic when he has not been found to have committed a criminal act. The committee approved the standing orders of the Prison Commissioners which recommend that a prisoner be left to stand his trial unless there are strong reasons to the contrary. It remarked that it was aware of evidence of persons of unsound mind having pleaded guilty either to gratify an insane desire for punishment or to avoid inquiry into their mental condition. The evidence which justifies a finding of unfitness to plead consists of showing that a prisoner suffers from such defect or disease of the mind as not to be able to understand the nature of the proceedings against him, or the difference between a plea of "guilty" and a plea of "not guilty," or that he is unable to follow the course of the trial or instruct counsel in his defence or appreciate that he has the right to challenge a juror. On these points the medical witness can state the facts he has observed and the conclusions he has formed, but it is for the jury to decide the issue. The law sees no inherent difficulty in a man or woman being insane and yet fit to plead.

By way of illustration Dr. Higson mentions two instances of the kind of complication which may be introduced. A woman was to be tried at Liverpool assizes for murder of her child. She was brought from Manchester where the medical officer had reported that, during remand there were no indications that she would be likely to be unfit to plead on arraignment. Yet on arrival at the Liverpool assize-court she was in such a state of extreme emotion and mental distress that the medical witness was prepared to give evidence, from further observation, that she was not fit to plead. In the other instance the prisoner had been charged with shooting with intent to murder. His mental condition indicated a straightforward case of paranoia. Medical witnesses for the defence testified that he was unfit to plead. He protested and, his counsel not objecting, the judge told the jury to return a verdict that the man was fit to plead. He was then indicted and, in spite of protests from his counsel, he pleaded guilty; the result was a sentence of 20 years' penal servitude. Dr. Higson records the interesting opinion of one of the medical witnesses, who discussed the case afterwards, that the judge overlooked the unlikely contingency of the prisoner pleading guilty, and that the jury was the more ready to follow the direction to find the man fit to plead because they were anxious to hear what was rather a sensational case.

STERILISATION IN THE U.S.A.

IN May of 1934 a committee of the American Neurological Association was appointed to evaluate in a critical manner the problems of the inheritance of various mental abnormalities and neurological disorders. The committee consisted of Dr. Abraham Myerson (chairman), Dr. James B. Ayer, Dr. Tracy J. Putnam, Dr. Clyde E. Keeler, consultant in eugenics, and Dr. Leo Alexander, research associate. The committee was subsidised by a grant from the Carnegie Foundation. The conditions under which it was appointed and the method of its procedure have something in common with those which related to the recent Departmental Committee on Sterilisation (the Brock Committee). Its report shows that the possible benefits of sterilisation seem to have been exaggerated in America in much the same way as in this country. In a preface the committee states:

We have tried to free our minds from the obsessive traditions of psychiatry and eugenics and this report is, we believe, as unbiased and critical and as nearly objective as we can make it. We hope that the subject matter of the report and the recommendations will be of value both in evaluating past work and as the basis for legislative and especially for research activity.

THE COMMITTEE'S FINDINGS

The findings of this committee are set forth in 12 chapters, of which the last consists of a valuable and comprehensive list of references occupying no less than 16 pages. Arguments commonly used for and against sterilisation receive careful consideration. In the fourth chapter of the report the contention that a need for sterilisation is created by the increase of mental disorders in the United States is examined. An interesting analysis is made of the commitment rate in two States wherein the psychiatric services are highly perfected—namely, Massachusetts and New York. The conclusion is reached that if certain relevant factors are taken into account, there are no valid reasons for supposing that an increase in mental disorders has taken place. The better organised the hospital services, the greater will be the inducement to solicitous relatives to consent to the commitment of mentally abnormal persons; the increasing age of the community, moreover, naturally leads to an increase in the proportion of senile psychoses admitted into mental hospitals.

In a discussion of the relation of genetics to eugenics, the American committee reaches conclusions closely similar to those of the Departmental Committee. They stress the importance of the interaction between hereditary and environmental factors. Recent genetic investigations are quoted in support of the view that "the environment may be conceived as a releasing agent for the manifestation of a character without which, so to speak, the character could not appear." Chapter 7 consists of some shrewd criticisms of widely accepted investigations bearing upon the inheritance of mental diseases and defects. These criticisms pave the way for the committee's chief recommendation, namely, that a—"concerted, co-ordinated and planned long-time research should be instituted in some State which is well-organized psychiatrically and socially, and which has a stable population. A central group headed by a full-time director should determine, after due study, the technique of research, this being the first and all important step. Certain hospitals might be selected to study the mental diseases, feeble-mindedness and epilepsy, through the operations of a genetic group stationed therein. Arrangements could be made for the study of samples of the total

population through schools, universities, factories and such other institutions and social aggregations as may be decided upon."

As is to be expected, the report is sceptical as to the possibility of eliminating crime by genetic methods. "Most writers," they say, "agree that while there may be a constitution (favouring criminality), the effort to breed it out by any eugenical measures is, in the present state of our knowledge, not to be recommended and that more fruitful approaches to crime are to be found in social measures of one type or another." With regard to the relation between genius and mental abnormalities, the committee state categorically that "feeble-mindedness breeds no genius and that we have nothing to fear on that score from the sterilisation of the feeble-minded"; but a different view is taken of the effect of the indiscriminate application of the sterilisation law to manic-depressives. Referring to the work of Lange-Eichbaum, they are satisfied that valid and reliable evidence has been adduced to indicate that sterilisation, applied as a wholesale measure to manic-depressives and their relatives, might well cut off from the race some of its most valued and valuable members.

RECOMMENDATIONS

The committee's most important recommendation, the promotion of further research, has already been noted. But they make some further recommendations which they preface by the three following statements of opinion: (1) our knowledge of human genetics does not justify us in advocating the sterilisation of people who are themselves normal; (2) there is at present no scientific basis for sterilisation on account of immorality or character defect; (3) nothing in the acceptance of heredity as a factor in the genesis of any condition considered by this report excludes the environmental agencies of life as equally potent and, in many instances, as even more effective.

In the light of these statements, the following recommendations are submitted to the American Neurological Association for its considerations:—

(1) Any law concerning sterilisation passed in the United States under the present state of knowledge should be voluntary and regulatory rather than compulsory.

(2) Any law concerning sterilisation should be applicable not only to patients in State institutions, but also to those in private institutions and those at large in the community.

(3) The central machinery for administering any law should be one or several Boards composed chiefly of persons who have had special training and experience in the problems involved. These should study each case on its individual merits and should strongly urge, suggest, or recommend against sterilisation according to its findings. Cases could be brought before such a Board by superintendents of institutions, private physicians, parents, or guardians, or by the patients themselves.

(4) Adequate legal protection for members of such a Board and for the surgeons carrying out such recommendations should be secured by statute.

The committee feels that sterilisation is not to be recommended as a general measure applicable to all persons of whose infirmity a certain diagnosis has been made; they recommend it rather as applicable in selected cases of certain diseases subject to the consent of the patient and those responsible for him. They regard the measure as appropriate to the following conditions in the order given:—

(a) Huntington's chorea, hereditary optic atrophy, Friedreich's ataxia, and certain other disabling degenerative diseases recognised as hereditary.

(b) Feeble-mindedness of familial type.

(c) Dementia precox (schizophrenia).

- (d) Manic-depressive psychosis.
(e) Epilepsy.

A COMPARISON

The general resemblance between these recommendations and those of our own Departmental Committee will be obvious to persons familiar with the latter. Both committees advocate voluntary measures only, they recommend that they should apply to selected cases only, and that facilities for sterilisation should be made available to patients whether in State institutions or not. Both ask for adequate legal protection for the doctors concerned. The chief point of difference resides in the procedure recommended by which patients should apply to be sterilised. The Departmental Committee recommend that wherever possible the patient himself should apply; the American committee wishes to make it possible for superintendents of institutions and private physicians also to apply. The Departmental Committee recommends that each application, supported by two medical recommendations, be communicated to the Minister of Health who should be vested with the power of authorising or vetoing an operation; the American committee recommends that each case be adjudicated by a specially appointed Board. In this respect, its recommendations favour the type of safeguard now in practice in Germany.

VIENNA

(FROM OUR OWN CORRESPONDENT)

AGE-GROUPS OF DOCTORS

IN the course of an inquiry into the possibility of establishing old age pensions for medical practitioners, the Austrian Union of Practitioners (Reichsverband der Aerzte) has collected some interesting material relating to the age-groups of doctors in Vienna. The following Table indicates the general position:—

Age-group.	Male.	Female.	Total.
90-65 years old	550	2	552
64-45 " "	1256	90	1346
44-35 " "	1188	287	1475
34-25 " "	903	212	1115
Under 25 years	1	0	1
—	3898	591	4489

There are 872 (or 15 per cent. of the total) doctors aged 60 years and over, and it is proof of the hard times the medical profession is experiencing that they are nearly all still in practice. During the last 20 years either their savings have been lost or their practices and incomes have dwindled. Among the recommendations brought forward by the Union has been a scheme providing for pensions for all practitioners over 65 on condition they retire from practice and make way for the younger men. But to provide even the very modest pension of 250 Austrian schillings (about £10) a month a large capital fund would have to be collected, and under present conditions this is quite out of the question. The outlook is therefore not very encouraging.

TUBERCULOSIS REPORT FOR 1934

The recently published report of the health department of the Ministry of Social Welfare records that its fight against tuberculosis is conducted from 93 centres working with a staff of 153 doctors, 104 trained nurses, and 71 follow-up nurses, who advise the patients, keep in touch with them, arrange for

hospital or sanatorium treatment where necessary, and organise preventive work among the contacts. In 1934 31,793 new cases were registered, of whom 44 per cent. were men. Rather more than half were over 18 years of age. About 8 per cent., mostly from the country districts, were classified as seriously ill. The cases reported in Vienna itself were not so grave. In 60 per cent. of the cases other members of the family were found to be also infected, in 20 per cent. seriously. Altogether during 1934 280,740 patients attended the centres (65 per cent. at the clinics in Vienna), and of these 167,144 were kept under constant supervision, 8 per cent. being open tuberculosis cases. The 169,070 examinations conducted by the clinics included 11,114 sputum tests, 15,616 biological tests, and 32,296 radiological examinations. The homes of 49,611 patients were visited, and 28 per cent. were condemned as unhygienic, while 70 per cent. were found to be overcrowded—i.e., more than three people living in one room. Of the gravely ill patients only 33 per cent. had a room to themselves, and 16 per cent. of them had to share even their beds. The amelioration of these conditions is the chief aim and work of the clinics.

RECENT LOSSES IN THE MEDICAL FACULTY

Prof. Constantin Bucura, the eminent gynaecologist, has died suddenly at the age of 62. Prof. Bucura, who was of Greek descent, and held the position of chief of the department of gynaecology at the Vienna Polyclinic, where he attracted many students from the Balkan cities. He first won recognition with his work on the theory of conception and fertility, but his most recent researches dealt with cancer of the uterus and ovaries. The death is also reported of Dr. Norbert Dohan who fell a victim to an affection of the blood as a result of his work as chief radiologist of the "Krankenkasse." Dr. Fritz Passim, director of the Children's Hospital of the second district of Vienna, has also died at the age of 67. He was well known as a bacteriologist and for his research work in tuberculosis, especially tuberculous meningitis.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

EDINBURGH ROYAL INFIRMARY

THE ambitious extension and reconstruction schemes undertaken by the management of the Royal Infirmary of Edinburgh are causing considerable anxiety to their promoters. In the annual report for the year ending Sept. 30th, 1935, the managers point out that £150,000 is still required to complete the scheme. A further appeal will shortly have to be made to the public for the necessary funds. The new maternity wing is rapidly taking shape, and the foundations of the new nurses' home have been laid. It is hoped that the full scheme will be completed by Whitsunday, 1937, when the management have promised to take over the functions of the Edinburgh Royal Maternity and Simpson Memorial Hospital. The large new block near the west gate, which is almost finished, is to be used for the treatment of diseases of the skin and venereal diseases, and the wards at present devoted to the treatment of these diseases will be converted into surgical wards to help relieve the ever-increasing surgical waiting-list. Reconstruction of the boiler-house is to cost £22,000, and new X ray apparatus will cost over

£10,000, for the X ray equipment, which was the best obtainable in 1926, is now out of date and will have to be scrapped. The number of patients treated during the year as in-patients was 20,695 (daily average 936), while the 67,583 new out-patients seen during the year represented an increase of 791 over the previous year's figure. Motor accident cases admitted to the wards numbered 366, and half the cost of maintenance of these cases was recovered from insurance companies. The managers report a satisfactory increase in ordinary income. The deficit on the ordinary account amounts to only £28,000, but to this must be added the deficiency on auxiliary institutions, and sums amounting to nearly £27,000 which were expended under the heading of extraordinary expenditure, making a total deficit of over £61,000. Fortunately nearly £75,000 was received in the form of free legacies during the year, and bequests for endowment purposes amounted to over £18,000. In conclusion the managers point out that the large additions being made to what is already the largest voluntary hospital in Britain must lead to a considerable increase in the annual expenditure.

IRELAND

(FROM OUR OWN CORRESPONDENT)

TUBERCULOSIS IN CATTLE

A YEAR or two ago Dr. James Ryan, Minister for Agriculture in the Irish Free State, held out hope that in his work of reducing the number of surplus cattle in the country, special attention might be given to the elimination of tuberculous stock. Last week he informed a congress of the Irish Dairy Shorthorn Breeders' Society that such a scheme was impracticable. His reasons are somewhat puzzling. On the one hand he maintained that there is no need for alarm in regard to tuberculosis, and stated that the investigations that had been carried out had shown that things were not nearly as bad in their herds as they had feared. On the other hand, he said that the elimination of tuberculosis would cost millions of money, would require more veterinary surgeons than they had in the country, and would take many years to accomplish. It is difficult to reconcile these statements. Dr. Ryan's opinion that there is no need for alarm in regard to tuberculosis will not carry conviction. The thousands of tuberculous children in the hospitals throughout the country as the result of drinking tuberculous milk speak too loudly in reply.

PARIS

(FROM OUR OWN CORRESPONDENT)

MEDICAL PRIZES AND AWARDS

THE French Academy of Medicine is the judge and donor of many prizes for the advancement of medical science. This year it has awarded 52 such prizes. At a meeting of the Academy of Medicine on Dec. 10th, a report was presented on the prize-winners for 1935. It is curious how varied are the conditions laid down by the donors for the winning of these prizes. The Ernest Guérétin Prize is awarded to the authors of works based on clinical observations made on the human being, without any sort of vivisection or any experience depending on animals. It needs no superhuman insight to fathom the donor's attitude towards vivisection. His prize was this time shared, Dr. Antonelli, author of a clinical, anatomical, and radiological study of the

"poumon cardiaque au cours de l'insuffisance auriculaire gauche" receiving four-fifths of the prize, and Dr. Liège the remainder for his study of the indications, results, technique, and accidents of blood transfusion. The Baron Larrey Prize for the best work on medical statistics was also divided last year, between Dr. Fricker for his study of the Schick reaction and its relation to endemic diphtheria in France, and Dr. du Bourguet for his study of penetrating wounds of the abdomen. The Lefèvre Prize for the best work on melancholia was not awarded, an ætiological and clinical study of Morel's melancholia being considered worthy of honourable mention, but no more. Applicants for such prizes must send in their theses to the Secretariat of the Academy of Medicine before March 1st of the year in which the prize is to be awarded. The text must be in French or Latin, and the Academy of Medicine is the sole judge. For some prizes the applicants must be anonymous; for others, anonymity is optional; and for others, again, it is forbidden. For some prizes only printed works are considered. With certain important exceptions, foreigners as well as Frenchmen are eligible.

A QUESTION OF HOSPITAL ADMINISTRATION

FOR nearly a year there has been disagreement between the hospital authorities and the majority of the honorary medical staff of the Bermondsey Medical Mission Hospital for Women and Children on a matter of principle. The disagreement has now culminated in the resignation of the members of the honorary staff. We understand that in February, 1935, six members of this staff sent a letter to the hospital committee making a recommendation, concerning an appointment to the resident medical staff, which was disregarded by the hospital committee who disapproved of this method of approach. After prolonged discussion and correspondence the members of the honorary medical staff came to the conclusion that there were certain unsatisfactory features in the organisation of the hospital. For example, there was no provision for a medical committee of members of the active staff, and medical appointments to this staff and decisions on medical matters were often made without consultation with the honorary staff. During the course of the discussions it was indicated to the six members of the staff that the medical director of the hospital proposed to close those departments of the hospital for which these six members were responsible. Members of the honorary medical staff then asked that the administration of the hospital should include a medical committee formed of the medical director and the active members of the honorary staff, for the purpose of advising on medical matters, including appointments to the staff. It was intimated on behalf of the hospital authorities that this suggestion was unacceptable. The six members finally resigned from the hospital staff in October, 1935, because they considered the existence and recognition of a medical committee with the usual functions to be essential in the interests of the hospital and its patients, and they were given the full support of their colleagues on the honorary staff.

The Bermondsey Medical Mission Hospital was founded in 1904 and rebuilt in 1928. It is staffed entirely by women doctors, and contains 20 beds and two private wards for paying patients.

OBITUARY

THOMAS HENNESSY, F.R.C.S.I., D.P.H.

Dr. Thomas Hennessy, who died suddenly in Dublin on Thursday, Jan. 2nd, was well known in the political and medical world. He was Irish secretary of the British Medical Association and arrived at his office as usual in the morning. After attending to correspondence he called at a neighbouring office where he collapsed and breathing ceased. He had suffered for many years from myocardial weakness and had long anticipated a sudden end, although his general condition recently had not given rise to any immediate anxiety.

Thomas Hennessy was born 65 years ago in Limerick, and received his medical education in Queen's College, Cork, and took the Irish double diploma in 1894, having as a student distinguished himself as a Rugby football player. In 1898 he was admitted to the fellowship of the Royal College of Surgeons

DR. HENNESSY

in Ireland, and in 1902 he obtained from the College the Diploma in Public Health. He started as a country practitioner and then acted for a long period as dispensary medical officer of the Clogheen district, Tipperary, where he made himself a fine and more than local reputation. He was an able and particularly sympathetic practitioner and as a result of his strenuous work in practice he developed the cardiac weakness which shortened his life. From the time of his entry to the profession he became interested in medico-political affairs; he was an active member of the council of the Irish Medical Association, and in the special struggles which lay before the Irish medical profession on the introduction of the first National Health Insurance Bill, Hennessy was recognised as one of the most capable and energetic leaders. When, just before the war, the B.M.A. decided to establish a secretariat in Ireland Hennessy was offered the position of secretary, and though loth to leave practice, was influenced by his delicate condition of health to accept the post, which he held to the end of last year when he took up the duties of medical secretary to the Irish Medical Union which replaces both the I.M.A. and the B.M.A. in the Irish Free State. His energy and capacity were notable in his official business and undoubtedly his long experience as a country doctor fitted him for dealing with the problems which came before him, such as, for example, the settlement of the dispute between the medical profession and the National Health Insurance committees concerning the certification of insured persons and their title to benefit. The remuneration of the medical profession and the conditions of a poor-law medical service also presented difficulties in which Hennessy proved to be as reasonably conciliatory as he was

strong in advocacy of what he considered right. It was mainly owing to his personal influence that these struggles terminated satisfactorily, if not completely so, for the medical profession. The War Office was also indebted to his administrative work on the medical war committees, for undoubtedly the part that he played at the deliberations of these bodies led to considerable recruiting of young Irish men to military service of the Crown. It goes without saying that to such a man individual practitioners in difficulty would often turn for advice, and over and above his official work he was hugely occupied in giving advice to junior medical men who found themselves in difficulties, when it was characteristic of him that he gave his assistance without inquiring if those who sought it were members of the bodies to which he was secretary.

All this official work led to no narrow concentration on the professional side of the many questions that came before him. On the contrary, Hennessy always had as his main object the welfare of the public, so that it came about that he was not only the champion of the medical profession in movements for redress of general grievances and the confidential adviser to numerous individual medical men, but also was the persistent advocate of all movements to improve public conditions and promote public health service in Ireland. He may be regarded as having been the father of modern health reform in the Irish Free State. It was mainly through him that the Irish public health council was established in 1919 and all subsequent health reforms may be regarded as having been placed in his hands. He entered general politics in a noticeable manner, being elected to the Dáil in 1927 for South Dublin on the vacancy caused by the death of the Countess Markievicz. While a member of the Dáil he took a prominent part in public affairs. He was a convinced Nationalist and gave his support to the Cosgrave party on the formation of the Irish Free State, and in coöperation with the late Sir James Craig paid particular attention in the Irish Parliament to matters concerning health. He was twice elected to the South Dublin seat and his common sense, honesty, and generally sympathetic attitude were so manifest that there was general regret when he lost his seat some six years later.

Our Dublin correspondent writes: "No account of Hennessy's public work will convey to those who did not know him a due impression of his winning personality. Honourable, broad-minded, far-seeing, nothing really roused his anger but intrigue or unfairness. He would shock his party colleagues by his frank denunciation of policy of which he disapproved. A hearty lover of his own country he had no ill-will to any other country. His judgments were sometimes impulsive but always independent and generous. A strong party-man he would often see little good in the other party, in which nevertheless he had invariably many personal friends, and even in sharp controversy he would disarm hostility by a joke or a smile. A born fighter he never fought but in what he held to be a right cause and never for himself. In recent years his health sometimes gave rise to anxiety and he knew that his life was uncertain, but his courage and activity did not fail. He died as he would have wished, but his sudden leaving is a grave loss to the profession to which he gave his best energies and to his country as a whole."

**GEORGE DOUGLAS MATHEWSON, B.Sc., M.B.,
B.Ch., F.R.C.P. Edin.**

Dr. George Mathewson, who died on New Year's eve, was the son of Mr. James Mathewson, of Dunfermline, and received his medical education at the University of Edinburgh, where he was Mouat scholar and graduated in 1905 as B.Sc., and M.B., Ch.B. He acted as house surgeon at the Royal Hospital for Sick Children, Edinburgh, and house physician at the Royal Infirmary, where he was also clinical tutor in medicine. He was appointed assistant physician to the Leith Hospital and later filled the same post at the Royal Infirmary, while he was also physician to the Royal Public Dispensary in Edinburgh. Elected F.R.C.P. Edin. in 1912, he became lecturer in clinical medicine in the University of Edinburgh and full physician at the Leith Hospital and at the Royal Infirmary. Both the University of Edinburgh and the Royal Infirmary have lost in him a distinguished colleague and able teacher, while his infrequent writings showed the special direction of his studies as a cardiologist, which were recognised also when he became responsible for the organisation of a cardiological department at Salonika during his period of war service. He was a member of the Association of Physicians of Great Britain.

Mr. J. M. Graham, Ch.M., F.R.C.S. Edin., has sent the following appreciation of his colleague:—
“The death of George Mathewson has come as a great blow to the medical profession in Edinburgh. His friends knew that he had successfully passed the crisis of a serious attack of pneumonia. He was apparently well on the road to recovery when, on the last night of the past year, the blow fell, and it was learned that he had suddenly passed away. Although only promoted to be one of the senior physicians at the Royal Infirmary 18 months ago, he had already during his years of service as assistant physician, and as physician to Leith Hospital, established his reputation as a consultant, and as a teacher of clinical medicine. Those of us who knew Mathewson as a student at Edinburgh University, felt that he would be successful in whatever branch of professional work he adopted. Even as a senior schoolboy he had the ability and character, which, without any strong effort on his part, led him to the top of his class. His medical work was on the same high plane, and it was characteristic of him that it should be accomplished easily and with no apparent strain. Above all, he enjoyed his hospital work, and his contact with students. No one could have shown more consideration for the feelings of his patients. Mathewson's first and last thought was for the individual he was treating. That his patients appreciated his kindly methods was obvious to any one who accompanied him during a ward visit. The research work which Mathewson carried out in the clinical laboratory of the Royal Infirmary established his reputation as an authority on the physiology and clinical pathology of the heart. His special knowledge in this branch of medicine was recognised when, during his period of war service, he was nominated to organise a cardiological department for the Salonika Army. Although Mathewson did not contribute regularly to medical literature, what he did write was always original and a definite contribution to knowledge. He was the last man to ‘cultivate’ a reputation. At staff and medical meetings he did not speak often, but his remarks were always very much to the point. His ideas were clear and concise, speaking came easily to him, and he had a flair for the ‘right word.’ He had a natural

gift for teaching, and enjoyed the appreciation of his students. In his own student days the teaching of clinical medicine in Edinburgh had reached a very high standard; Mathewson had already shown that he was well equipped to maintain this fine tradition. Nothing gave him greater pleasure than the knowledge, just before his last illness, that his ward team had reached the final in the Old Residents Cup Rugby Competition.

“Mathewson was always on the best of terms with his colleagues, and with those working under him. He was genuine and loyal in his friendships. He looked back with special pleasure on his period of war service in Macedonia, where many new friends were made and old friendships were confirmed. He was at his best as an active member of several of the famous Edinburgh medical dining clubs. For many years he had been one of the leading spirits in the Centenarian Club, and by none will he be missed more than by his fellow members. His reputation for wit and repartee was acclaimed when he was appointed secretary of the Medico-Chirurgical Club. His minutes at the biennial dinner were looked forward to as the chief entertainment of the evening. It was a pleasure to meet Mathewson in his own house. He was an ideal host. His intimate friends knew how perfectly happy he was in his home life. To his widow and to his children, a daughter and a son, all will offer heartfelt sympathy.”

EDMUND VALENTINE GIBSON, M.D. Edin.

THE death occurred on Dec. 23rd of Dr. E. V. Gibson, of Grange, Guernsey, where he had been in practice for many years. Born in Derbyshire in 1865, the son of the Rev. A. A. Gibson, of Stanley, he was educated at Trent College and entered the University of Edinburgh as a medical student. He graduated as M.B., C.M. Edin. in 1890 and in the same year was appointed house surgeon to the General Hospital, Birmingham. Thereafter he held resident posts at the East London Children's Hospital, at the Devonshire Hospital, Buxton, and was for a time resident medical officer to the Victoria Infirmary, Glasgow. At different times while holding hospital appointments he made interesting clinical communications to THE LANCET, for he was a very competent and well-informed man. He then, some forty years ago, established himself in practice at Guernsey, was appointed surgeon to St. Peter's Port Hospital and to other institutions on the island, and conducted a large practice, latterly in association with his nephew, Dr. R. E. Gibson, and his son-in-law, Dr. W. B. Fox. During the war he served with the rank of surgeon-major in the 1st Royal Guernsey Light Infantry. Dr. Gibson had been a great athlete during his university days, and in later years became an enthusiastic horticulturist, possessing at his villa “Paradis” a remarkably beautiful garden. He was 70 years of age at his death and was on the eve of retirement.

**LILIAN MARY CHESNEY, M.B., Ch.B. Edin.,
D.P.H. Durh.**

THE death took place at the close of the year in Palma de Majorca of Dr. Lilian Chesney, who for a time practised in London as a throat and nose specialist. She was the youngest daughter of General Sir George Chesney, author of the famous skit “The Battle of Dorking,” and received her education in Edinburgh where she graduated M.B., Ch.B. in 1899, afterwards taking out post-graduate courses at Vienna. She held clinical and residential appointments in various institutions before deciding to

practise as a laryngologist, and obtained the D.P.H. Durh. in 1908. On the outbreak of war she went as assistant surgeon with the Russian Unit of the Scottish Women's Hospital and was decorated with the orders of St. Anne and St. Sava. Later she acted as surgeon to the Serbo-English field hospital and recorded her experiences in the *Practitioner* in 1916, especially with regard to typhus fever. In 1920 she went to live in Majorca and from there communicated her impressions to the *Practitioner* of the Balearic Islands as a health resort. Dr. Lilian Chesney, who had many friends in England, promoted that habit of visiting the Balearic Islands for health and holiday purposes, which seems now to be firmly established.

JAMES DUNCAN HART, M.C., M.D., D.P.H. Glasg.

THE death occurred on Dec. 18th of Dr. James Duncan Hart, of North Walsham, Norfolk. A Glasgow man, he was educated at Pettes College and the University of Glasgow, where he graduated as M.B., Ch.B. in 1905. After some post-graduate work at Bonn he served as medical officer to a group of tea estates in Assam, but at the outbreak of war returned to be attached to the 12th Battalion of the London Regiment, and for his war service was more than once mentioned in despatches and awarded the Military Cross. He then settled at North Walsham where he was a member of the staff of the War Memorial Cottage Hospital, a keen supporter of the St. John Ambulance Brigade, and took a prominent part in the social life of the neighbourhood. His death, which occurred suddenly at the age of 52, was deeply regretted in the neighbourhood as was manifested by the large attendance at the funeral.

ROBERT TURNER, M.D. Aberd., F.R.C.S. Edin.

THE death is announced of Dr. Robert Turner at his residence in Llandudno, where he had retired after many years' practice in Bootle. Born in Banff, Dr. Turner received his medical education in Aberdeen and Liverpool. He graduated as M.B., C.M. Aberd. in 1894 and later proceeded to the M.D. degree, acquiring also the diploma of F.R.C.S. Edin. Shortly afterwards he started in practice in Bootle, where he attained success through his skill and his devotion to his work. He also took an active interest in the civic affairs of the borough and acted as mayor of Bootle in 1923-24. He had only recently retired from practice and was in good health until a sudden illness, necessitating operation, proved fatal, in his sixty-sixth year.

JAMES HARRISON, M.R.C.S. Eng., L.S.A.

Dr. James Harrison of Garstang died on his seventy-eighth birthday on Dec. 28th. He was educated at Windermere College and proceeded to St. Bartholomew's Hospital for his medical training, qualifying in 1879 as M.R.C.S. Eng., L.S.A. After a short period of service at the Blackburn Infirmary he settled in Garstang over 50 years ago and took a prominent part in the public and social life of North Lancashire for nearly half a century. He was a member of the Garstang rural council for many years and served as a representative on the Lancashire county council. Shortly after retiring from practice some 15 years ago he was appointed a magistrate for the county, sitting on the same bench at Garstang with one of his daughters, also a county magistrate.

PANEL AND CONTRACT PRACTICE

Light Treatment as Medical Benefit

As a rule when an insurance practitioner administers light therapy he can charge the patient for it and, upon submitting form G.P. 45 to the insurance committee, no question is raised as to its being a specialist treatment. Provided the practitioner satisfies the local medical committee that he has the necessary qualifications he retains the fee he has charged. It may well be argued that the degree of skill required for the administration of light treatment is not beyond the scope of a general practitioner—it must be remembered that the treatment which a practitioner is required to give to his patients comprises all proper and necessary medical services other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess—but it is not every practitioner who possesses, or can reasonably be expected to possess, the apparatus for applying light treatment. While too it is a truism that every case is dealt with on its merits and that a decision on a particular case does not necessarily enunciate a principle, it is equally clear that a decision on a case may establish a presumption that the service is or is not within the scope of a practitioner's obligations, as for example the treatment of varicose veins by sclerosing fluid, and it is probably this reason which has led local medical committees to regard light treatment as outside the scope of medical benefit.

The Croydon local medical committee, however, are taking rather a different view, and in fact a few years ago decided that six cases of electrical treatment

were not of a specialist character. That committee, in respect of two recent cases of sunlight treatment, have given their unanimous opinion that the service in question was not of a kind which involved the application of special skill or experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess. The grounds upon which their opinion is based are that while in certain cases electrotherapy would have to be regarded as a specialist service the treatment referred to in these cases is not within that category as, with the modern apparatus now available, any practitioner can reasonably be expected to perform such service. The insurance committee have concurred in the view of the local medical committee and the insured persons concerned will have their fees repaid to them.

The Insurance Acts Committee have already given their view that the general practitioner must be expected to keep reasonable pace with advances in medical science and, in a letter, they go so far as to indicate that ultra-violet ray treatment is not necessarily a specialist treatment, but that the question whether in particular cases the service is within the scope of a practitioner's agreement can only be decided in the full light of all the local circumstances. Most committees still hold that light treatment is outside the scope of medical benefit.

More Friendly Guidance

In another of what he calls his "written chats" the clerk of the London insurance committee devotes three paragraphs to the evergreen subject of medical records. While congratulating practitioners upon the improvement in the return of these

documents he rather cunningly takes advantage of the opportunity to indicate that the cases of ten particularly bad offenders have had to be referred to the medical service subcommittee. Then follows a reminder about the immediate transmission of records upon the death of insured persons. Practitioners are required in such circumstances to forward the medical record at once, without awaiting a formal notification from the committee, but the name of the deceased is not removed from their list until the fact of the death has been verified by the approved society. The action of some practitioners in refraining from sending in the records of persons known to be dead means in effect that they are claiming credits in respect of persons for whose treatment they are no longer responsible, and, what is worse, in respect of whom the practitioners' fund is receiving no money. But the question may be asked whether a record should be sent in if the patient has died while not under the care of the practitioner. Certainly it should, even if the endorsement has to be "said to have died in hospital" because, as indicated above, the fact of

death has to be verified before other action is taken by the committee. Sometimes the first intimation received by the practitioner is the form G.P. 34, but in other cases he will know of the death long before the society or the committee does.

The letter goes on to remind practitioners of the desirability of notifying acceptances at frequent intervals—the terms of service prescribe "within seven days." The practitioner who sends in no acceptances at all during the quarter and then on the last day sends over 50 is making things hard for himself and putting sand in the mechanism of the Act. On prescribing appear two little notes which almost deserve to be called wise-cracks: (1) don't issue prescriptions on the committee's form to persons about whose title to benefit you have doubt, and (2) if you wonder whether you may properly prescribe a particular preparation don't ask the patient or the chemist to inquire. "We try," says the clerk, "to reply tactfully to inquiries by insured persons, but this is a matter which should be dealt with between the doctor and the committee direct."

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. to Surg. Cpts.: J. A. O'Flynn, G. V. Hobbs, and J. G. Boal.

Surg. Comdr. (rettd.) A. A. Sanders, O.B.E., to rank of Surg. Capt. (rettd.).

Surg. Lt. A. K. Stevenson to rank of Surg. Lt.-Comdr.

Surg. Lt.-Comdrs. (D) to Surg. Comdrs. (D): E. G. Adams, F. R. P. Williams, T. E. Brevator, and J. L. Edwards.

Surg. Comdrs. K. A. I. Mackenzie to *President* for course, H. L. Douglas to *Titania*, M. Barton to *Apollo* (on coming), and J. C. Sinclair to *President IV*.

Surg. Lt.-Comdrs. G. Phillips to *President* for course, and A. N. Forsyth to *Victory* for R.N.B., to *Boscawen* for H.M. Naval Base, Portland, and to *Drake* for R.N.B., addl.

Surg. Lt. T. McCarthy to *President* for R.A.F. Medical Officers' course.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdrs. to Surg. Comdrs.: G. McCoull and St. G. B. D. Gray.

Surg. Lt. A. E. Williams to *Royal Sovereign*.

Surg. Sub-Lt. R. V. Jones to *Victory* for R.N. Hosp., Haslar, for training.

ARMY MEDICAL SERVICES

Col. C. R. Millar, D.S.O., late R.A.M.C., having attained the age for retirement, is placed on ret. pay.

Lt.-Col. J. C. L. Hingston, from R.A.M.C., to be Col.

ROYAL ARMY MEDICAL CORPS

To be Bt. Cols.: Lt.-Cols. J. A. Manifold, D.S.O., and B. Biggar.

Maj. E. A. Sutton, M.C., to be Lt.-Col.

Short Serv. Commissions: Lts. R. S. Vine and J. E. Jameson to be Cpts. Capt. L. E. Odlum resigns his commn.

SUPPLEMENTARY RESERVE OF OFFICERS

Capt. R. W. Agnew resigns his commn.

TERRITORIAL ARMY

Col. L. A. Harwood, T.D., from 56th (1st Lond. Div.), is apptd. A.D.M.S., The Lond. Div.

Maj. J. Melvin, M.C. (late R.A.M.C., Militia), to be Maj.

Capt. R. W. Agnew (late R.A.M.C., Supp. Res.) to be Capt.

Capt. C. M. Forbes to be Maj.

To be Bt.-Majs.: Cpts. R. W. Gemmill, E. C. Woodhead, J. E. McCartney, and T. F. Arnott.

Lt. R. M. Allardye to be Capt.

Capt. D. R. W. Burbury relinquishes the appt. of Divl. Adj. 47th (2nd Lond.) Div. and Sch. of Instn.

Capt. D. C. McC. Ettles, from 56th (1st Lond.) Div., to be Divl. Adj., Lond. Div. and Sch. of Instn.

Supernumerary for service with the O.T.C.: G. E. Gray (late Offr. Cadet C.S.M., Queen's Univ. Belfast Contgt. (Med. Unit), Sen. Div., O.T.C.) to be Lt. for duty with the Med. Unit of that Contgt.

ROYAL AIR FORCE

Wing Comdr. J. Rothwell to R.A.F. Station, Manston, for duty as medical officer.

Flight Lt. L. Freeman is promoted to the rank of Squadron Leader.

Dental Branch.—Flying Offr. W. V. A. Denney is promoted to the rank of Flight Lt.

INDIAN MEDICAL SERVICE

Col. A. W. M. Harvey to be Maj.-Gen.

Lt.-Col. S. G. S. Haughton, O.B.E., to be Col.

Lt.-Col. B. C. Ashton to be Bt. Col.

The undermentioned officers retire: Col. C. A. Gill and Lt.-Col. J. D. Sandes.

(For New Year Honours in the Services see THE LANCET, Jan. 4th, p. 60.)

COLONIAL MEDICAL SERVICE

The following have been appointed medical officers, West Africa: Dr. G. T. Balean, Dr. D. L. Cran, Dr. C. A. McComiskey, Dr. J. L. McLetchie, and Dr. W. R. Phillipps. Dr. W. T. C. Berry has been appointed medical officer, Nyasaland; Dr. I. T. Dickson, medical officer, Malaya; Dr. J. F. Jarvis, medical officer, Tanganyika; and Dr. F. J. Wright, medical officer, Kenya. Dr. H. J. O'D. Burke-Gaffney becomes senior pathologist, Tanganyika; Dr. H. Fairbairn, sleeping-sickness officer, Tanganyika; Dr. G. Maclean, deputy director of medical services, Tanganyika; Dr. A. Rankine, director of medical services, Trinidad; and Dr. H. C. Towell, medical officer, Uganda.

DEATHS IN THE SERVICES

The death occurred on Dec. 31st, at Caorleon, Monmouthshire, of Lieut.-Colonel WILLIAM ALBERT MORRIS in his 79th year. He was educated at King's College, London, and qualified L.S.A. 1879, L.R.C.P. Edin. 1880. Two years later he joined the R.A.M.C., becoming major in 1894 and colonel in 1902. He served in Burma in 1886-87, and on the North West Frontier (Tirah) in 1897-98. He retired in March, 1912, but was re-employed during the European war. A frequent contributor to the medical press Colonel Morris is best known as editor of the "Treatise on the Transport of Sick and Wounded Troops," written by Surg.-General Sir Thomas Longmore.

CORRESPONDENCE

HYPERVITAMINOSIS D

To the Editor of THE LANCET

SIR,—In connexion with this subject, and Dr. Thatcher's paper thereon in last week's issue of THE LANCET (p. 20), attention may be directed to an investigation by L. L. Madsen, C. M. McCay, and L. A. Maynard on Synthetic Diets for Herbivora, with special reference to the Toxicity of Cod-liver Oil,¹ which may not be generally accessible. Sheep, goats, rabbits, and guinea-pigs were fed on a "synthetic" diet, consisting essentially of regenerated cellulose, starch, sucrose, yeast, salts, and lard, with cod-liver oil. Upon it sheep were reared successfully, goats with moderate success, but rabbits and guinea-pigs with much less success. Eventual failure in the last-named animals, and to a less extent in goats, was caused by the development of paralysis due to degeneration of the skeletal muscles, fatty liver being a constant finding in all species. It was demonstrated that the cod-liver oil was the chief causative agent in production of the lesions. It was found that for sheep and goats a daily intake of 0.7 g. of oil per kilo of live weight caused death within 93 days, 0.35 g. within 226 days, and only when the oil ration was reduced to 0.1 g. was no ill-effect produced.

The authors state that, while furnishing no evidence applicable to the human species, the results should serve to re-focus attention on the reports of Agduhr, Mouriquand and Michel² have also reported a relationship between cod-liver oil intake and the development of scurvy, the oil apparently in some manner "antagonising" the vitamin C. Cod-liver oil may not, therefore, be the entirely innocuous substance it is generally supposed to be.

I am, Sir, yours faithfully,

Greenwich, S.E., Jan. 4th. R. TANNER HEWLETT.

"MORBUS BRITANNICUS"

NEW LABELS AND LARGE TEXT-BOOKS

To the Editor of THE LANCET

SIR,—Bearing in mind that text-books of medicine now run to a couple of thousand pages, cost a couple of pounds, and become "out of date" every three or four years, I read with gloom of Dr. Kofoed's new "morbus Britannicus" which he describes in your last issue. Surely Dr. Kofoed has only described the signs and symptoms of acute vagotonia, which in this case is of occupational origin, occurring in stokeholds and ships' galleys for the most part. Such a well-known syndrome could scarcely be called a new specific disease; nor, in my opinion, can it be termed Britannic, since I have seen at least one very acute case amongst Chinese firemen, in four voyages to the East as ship's surgeon. The aetiology as given in the note would seem to be indefinite: in my case the weather was calm but very hot, and the men were of good physique, neither starved nor given to excesses (at sea), and with only their normal lues infection. I have yet to learn that a salt-free diet can excite such fulminating symptoms, but if this is so then this cause did not operate, for these men ate plenty of salt meat, and especially salt pork, every day. Possibly some sudden deficiency in water absorption is a more probable explanation, with

cerebral and medullary stasis. The late Prof. W. E. Dixon was wont to remark that the blood was geared for albumin, sugar, and salts. It is not, however, geared for water, especially during heavy labour in stokeholds and galleys, with great loss of body fluid.

Dr. Kofoed mentions some of the other causes of the acute vagotonic syndrome, but others also are well known—psychical, inflammatory, reflex, and toxic—as in some cases of death in the first stage of chloroform anaesthesia, in which the patient may die of vagal cardiac inhibition, like a dog. Vagotonia varies in degree from the stage fright of the European actor or examinee to the ascaris-excited acute abdomen of, for example, the North Borneo Murut. The ascaris, indeed, is an important cause of the acute syndrome in the tropics, a cause which Dr. Kofoed does not mention. The syndrome is as classical as that of inflammation itself: bradycardia followed by tachycardia; colic followed sometimes by diarrhoea; pallor; sweating; constriction of the pupil followed by dilatation; spasms of voluntary muscles with some rigidity of the recti which may later become board-like; nausea and possibly vomiting. The spasms may be due to an extension of the excessive stimulation to the voluntary musculature. The diagnosis of the cause is facilitated by giving hypodermically a full dose of atropine (gr. 1/50), or better by washing atropine into the veins. This procedure quickly relieved the acute stokehold cramps and colic, but would have less effect when there is some continued peripheral stimulation. Hot salt baths relieve by the action of heat only, and, of course, no salts are absorbed from water through an oily epidermis.

Would it not simplify medicine if certain unnecessary and confusing labels were now discarded, and if new labels were reserved for new specific diseases, and then only given after a long probationary period? Could one, in conclusion, dare the opposition of publishers, and plead for a standard loose-leaf textbook of practical medicine, compiled and revised annually by the most authoritative committee of international expert physicians, to enable us more easily and at less expense to see the true growth of medicine in its proper perspective?

I am, Sir, yours faithfully,

London Fields, E., Jan. 6th.

A. J. COPELAND.

SYPHILITIC ANÆMIA OF PERNICIOUS TYPE

To the Editor of THE LANCET

SIR,—In your last issue (p. 24) Dr. C. R. Box and Dr. A. M. Gill report an instance of severe anaemia of the pernicious type associated with, and apparently due to, an active syphilitic infection in an adult; and they remark on the rarity of such cases. It is certainly difficult to understand why, if syphilis can produce such a condition, more is not known of it. I felt the force of this dilemma some three years ago in the case of a child of 5 years old with a strongly positive Wassermann reaction and a comparatively severe hyperchromic anaemia. Rapid recovery occurred with no medication other than mercurial inunction. As there was no evidence to suggest the presence of a hæmolytic anaemia undergoing spontaneous recovery, it was tempting to presume that the anaemia was due to poisoning of the bone-marrow by the syphilitic infection. I could, however, find no analogous instances in the literature, and at a gathering of a dozen paediatric

¹ Cornell University Agricultural Experiment Station, Memoir 178, June, 1935 (Ithaca, New York).

² Compt. rend. Soc. Biol., 1922, lxxiv., 1170.

physicians no one could recall having seen a similar case. The following is a brief account of the case:—

A girl, aged 5 years, was brought to the Paddington Green Children's Hospital for pallor which was said to have been getting rapidly worse for three weeks. She was admitted owing to her anæmic appearance. On the day of admission her father gave the information that he had had syphilis and that the patient, when an infant, had had a short course of treatment for the same disease. The girl was well-grown and well-nourished, and showed no stigmata of congenital syphilis. Her complexion was very pale, showing no bronzing of the skin, and her blood-serum showed no icteric tinge. Her blood W.R. was strongly positive. The liver and spleen were not enlarged. The red blood-cells numbered 2,150,000; hæmoglobin, 50 per cent.; colour-index, 1.16; and the white count was 8500 with a roughly normal differential count. The film showed marked poikilocytosis, anisocytosis, and polychromasia; there were a few nucleated red cells.

In this case no treatment was given except the ununction of a drachm of blue ointment daily. In ten days time the red cells had increased by over a million, and the hæmoglobin by 30 per cent. Reticulocytosis amounted to 3.4 per cent. At the end of three weeks' treatment the red cell count was 4,420,000, and the hæmoglobin was 95 per cent. The appearances of the blood film were those of normal blood.

I am, Sir, yours faithfully,

London, W., Jan. 4th.

REGINALD MILLER.

AGRANULOCYTOSIS

To the Editor of THE LANCET

SIR,—I am much interested in the article on agranulocytosis by Goadby, Worster-Drought, and Dickson in THE LANCET of Oct. 26th, 1935. The occurrence of meningitic symptoms, with changes in the cerebro-spinal fluid in this condition, recalls to my mind a similar condition reported four years earlier (New Eng. Jour. Med., 1931, ccv., 1238) by W. Dameshek and myself. This was the first report of central nervous system changes in a typical case of so-called infectious mononucleosis. Since then two other cases of a similar nature have been called to my attention: one reported by A. H. Johansen (Acta med. Scand., 1931, Fasc. 3, lxxvi., 269), the other reported to me personally this fall by Dr. Edwin M. Cole from the Massachusetts General Hospital.

It was stated in my original communication that changes in the cerebro-spinal fluid occur simultaneously with the cerebral and meningeal symptoms of certain internal diseases. Further, it was emphasised that symptoms referable to the central nervous system occur in the blood diseases, such as the leukaemias and infectious mononucleosis. The close parallelism between the cellular changes in the cerebro-spinal fluid and the changes in the leucocyte counts in the latter case was considered to be significant. It was also mentioned that there might be a close relationship between this disease and the syndrome variously called aseptic, epidemic, and acute lymphocytic meningitis.

During the past few years considerable interest has been shown in the literature in lymphocytic meningitis, as well as other obscure central nervous system infections. This was stimulated by the work of Armstrong (Pub. Health Rep., 1934, xlix., 1019), and of Rivers and Scott (Science, 1935, lxxxi., 439), which indicates that a filtrable virus is the causative agent of acute lymphocytic meningitis. These experimental investigations tend to show that this disease is a clinical entity.

Whether or not this is a fact remains to be seen. However, it was stated in my original article that "the concept of an aseptic meningitis is at best a vague one and almost as all-inclusive as the term encephalitis." The concept was emphasised at that time that these conditions were symptomatic of some generalised systemic disease. The article by Goadby and Worster-Drought illustrates again the familiar phenomenon of the association of central nervous system changes with systemic disease. The aetiology of agranulocytosis as well as of infectious mononucleosis is of course unknown. However, from the standpoint of the cerebral manifestations, which apparently may occur in both diseases, a fairly close relationship may be seen. It is conceded; nevertheless, that the report concerning the case of agranulocytosis is indicative of a chronic infection of the central nervous system, whereas my original case of infectious mononucleosis dealt with an acute cerebral disorder.

While it may be true that this report on agranulocytosis is unique in the literature, it seems to me that the crux of the whole situation lies in the larger concept of various systemic diseases of known and unknown aetiology, giving rise to changes in the central nervous system.

I am, Sir, yours faithfully,

SAMUEL H. EPSTEIN.

Harvard University Medical School, Dec. 23rd, 1935.

THE UNDESCENDED TESTICLE

To the Editor of THE LANCET

SIR,—We read with interest Mr. Denis Browne's letter in your issue of Dec. 28th, in which he suggested that there are two distinct types of undescended testes: (1) those suffering from a delay in development, which would be suitable for hormone treatment, and (2) those suffering from a congenital deformity, in which hormone therapy is contra-indicated and which are amenable only to surgery. The hormone treatment of undescended testes being at present only in the experimental stage, such suggestions are indeed of value.

It appears that one of Mr. Browne's criteria for classing a case as congenital deformity in which hormone treatment should not be undertaken is the presence of a hernial sac. Of the 9 cases which he quotes from our series as being unsuitable for hormone treatment for this reason, three (Nos. 14, 17, 20) had no detectable hernia before treatment and the testes descended successfully into the scrotum. Hernias developed during treatment, and operation will now be required for their relief. Of the remaining 6 cases which were unsuccessful, 3 (Nos. 9, 28, 29) had palpable hernia before treatment and 3 (Nos. 27, 30, 31) had not; thus the absence of a hernia does not necessarily indicate that the result will be successful. Nor is the failure to palpate the testes a sign that hormone therapy will be unsuccessful; in three of the cases under discussion (Nos. 27, 28, 29) the testes were not palpable and the result was unsuccessful; but in patient No. 1 both testes were palpable and a successful descent of both testes was obtained.

It would seem then that Mr. Denis Browne's suggestions do not get us much farther. We hope, however, that further experience of hormone therapy will disclose more definitely the type of case suitable and the type unsuitable for the treatment.

We are, Sir, yours faithfully,

A. W. SPENCE,

E. F. SCOWEN.

Dunn Laboratories, St. Bartholomew's Hospital and College, E.C., Jan. 4th.

PURKINJE'S EIGHT-RAYED STAR*To the Editor of THE LANCET*

SIR,—If on awaking in the morning the eyes be closed and covered with the hands the centre of the field of vision will appear alternately as light or dark in accordance with its sensitisation from the periphery. If when the disc is light it be observed very carefully there will be seen in it a black eight-rayed star (*) similar to an astigmatic clock. The centre of the star is the centre of the field of vision. This corresponds to the eight-rayed star seen by that minutely accurate observer, Purkinje, by intermittent light and pressure on the eye. It has been very generally neglected, probably because of its artificial appearance. One of the main rays is vertical and another horizontal.

I am, Sir, yours faithfully,

F. W. EDRIDGE-GREEN.

Board of Trade, S.W., Jan. 2nd.

MEDICAL EDUCATION AND BLOOD EXAMINATION*To the Editor of THE LANCET*

SIR,—This is an age of mechanisation, the individual is being superseded by the machine, and individualism in medicine is being submerged by specialism and team-work. This is no doubt a natural and rational development, owing to the great advance in medicine and its allied sciences during recent years. It is impossible for any individual to keep in touch with every modern development in its relation to medical practice, and the student of the present day has come to rely upon a multitude of counsellors—the pathologist, the bacteriologist, the biochemist, the radiologist, &c.—for a diagnosis.

The great majority of students however are destined for general practice, and many may find themselves isolated in country districts, where the props upon which they have hitherto relied are not readily accessible, and they have to depend upon their own resources. Does the clinical training at the medical schools supply all the requirements of the general practitioner? The average doctor, when examining a medical case, takes the temperature, counts the pulse, perhaps looks at the tongue, listens with the stethoscope to the heart sounds and the respiration, possibly takes the blood pressure, and, if there seems to be a special reason, examines the urine for albumin or sugar. If any further investigation is required, the patient is referred to a specialist. He certainly does not examine the blood, and yet the diagnostic value of a blood examination cannot be over-estimated. Without a satisfactory blood examination the diagnosis of the large class of blood diseases, which are frequently met with in practice, is impossible, and in some conditions, which are fortunately comparatively rare, such as agranulocytosis and pernicious anæmia, the patient's life may depend upon early diagnosis and prompt treatment.

Leucocyte counts, total and differential, are of assistance in the diagnosis of acute infections, and additional information can be derived from the Ameth count, an infection of any kind, whether accompanied by leucocytosis or not, being associated from its beginning with a "shift to the left." In addition to this, the leucocyte count is a valuable guide in prognosis, and gives an indication of the course of the disease and its response to treatment, the necessity for operative interference in pyogenic infection, and the prospect of recovery. It is no exaggeration to say that there is no other method of

clinical examination by which so much valuable information can be derived.

The technique of blood examination is simple and easily acquired. No elaborate equipment is needed: a microscope—preferably with a mechanical stage—a hæmocytometer, a hæmoglobinometer, slides, and a few stains, are all that are necessary. The process is interesting, even fascinating, and with practice a complete examination need not take much more than an hour. Why should not students be taught to use this method of clinical examination as a routine? Clinical clerks might be required to supply a record of the blood picture in their notes in every case for which they are responsible.

I am, Sir, yours faithfully,

HERBERT H. BROWN.

Worthing, Jan. 1st.

DUODENAL ULCER TREATED WITH HISTIDINE*To the Editor of THE LANCET*

SIR,—The following case may be of interest to your readers.

The patient, a Moslem, aged about 30, reported to me on Jan. 30th, 1935, with "chronic dyspepsia," stated to be of six years' duration. His history was typical of that of a duodenal ulcer. I had the patient radiographed for a barium-meal series on March 4th, and the duodenal cap showed an ulcer crater, which persisted after the stomach had emptied. From Jan. 30th to June 7th I treated him with alkalis and a gastric diet, without any improvement; if anything his "hunger pains" were getting worse. On June 8th I started him on a course of 24 daily intramuscular injections of histidine, using Hoffmann-La Roche's Larostidin, put up in 5 c.cm. ampoules. The injections are practically painless. After the fifth injection the patient stated that his hunger pains had disappeared, so I told him he could try whatever diet he fancied. The next day his gratitude seemed unbounded, as he said he was able to have a good square meal for the first time without any discomfort whatever. Since then he has eaten a normal diet and not had any trouble, except some flatulence occasionally.

In my opinion this case deserves special attention in view of the long history, the distinct pathological state of his duodenum, as seen in the skiagram, and the quick relief obtained, which up to now (nearly six months afterwards) seems a permanent cure. I had the patient radiographed again by a barium meal series on Dec. 4th and there is no evidence whatever of the previous ulcer. My thanks are due to Dr. P. A. Pierce, radiologist of the Ripon Hospital, without whose help I should not have been able to obtain the evidence of ulcer and the results of the treatment.

I am, Sir, yours faithfully,

Simla, India, Dec. 19th, 1935.

A. H. BARTLEY.

THE BRIGHTNESS OF THE POST OFFICE MESSENGER*To the Editor of THE LANCET*

SIR,—In your leading article of Jan. 4th on the Marriage of Public Health and Agriculture you state incidentally that "H. H. Bashford reports that Post Office messengers get bigger (though not necessarily brighter) from year to year." I think it should be made clear that the words between parentheses are editorial and not mine. From a long personal experience, I have an extremely high opinion of the brightness of the average Post Office messenger.

I am, Sir, yours faithfully,

H. H. BASHFORD,

Chief Medical Officer, G.P.O.

Jan. 4th.

*** We have the same opinion, and the interpolated words are no contradiction of it, taken in their context.—ED. L.

AMMONIUM CHLORIDE AS A DIURETIC

To the Editor of THE LANCET

SIR,—In their paper on "A Mercurial (Novurit) Suppository as a Diuretic for Cardiac Œdema" (THE LANCET, Jan. 4th) Dr. Parkinson and Dr. Thomson also discuss the use of ammonium chloride as an adjuvant and mention that "there is difficulty in disguising its salty taste." This difficulty as well as the other drawback frequently seen with the use of ammonium chloride in the ordinary form—viz., the occurrence of digestive disturbances—have been overcome by the introduction in 1930 of a preparation called Gelamon, which has been prepared by Halpern under the auspices of Saxl and Erlsbacher and which contains the ammonium chloride in a special form. The main features are the adsorption of ammonium chloride on gelatin which is then hardened in formalin. When given in this form not only is the taste of ammonium chloride effectively disguised but also there is scarcely any incidence of indigestion, as gelamon is not, or only to a negligible extent, decomposed in the stomach. Since its introduction it has been used on a large scale in the First Medical Clinic of the University of Vienna, and on the ground of what I have seen in that hospital as well as in my private practice I can recommend it.

Gelamon is manufactured as pastilles, each containing 0.4 g. of ammonium chloride; 15 pastilles daily and spread over the day should be given (preferably after meals) during the 48 hours preceding the administration of the mercurial diuretic, during the day of the administration, and in some cases also during the first day following the administration. Our observation has been that not only can a considerable increase in the diuretic effect be obtained, but that also cases which did not respond to the administration of a mercurial diuretic or had become refractory may become responsive by means of the use of gelamon in the way indicated.

I have been in communication with the makers of gelamon for the last few months and understand that gelamon will be obtainable in this country shortly. I am, Sir, yours faithfully,

Wimpole-street, W., Jan. 6th.

A. SCHOTT.

AN ALUMINIUM KETTLE

To the Editor of THE LANCET

SIR,—Might I suggest to Dr. Elwell, whose letter appeared in your issue of Dec. 28th, that he should refer to a monograph I wrote in 1931, entitled the "Danger of Food Contamination by Aluminium," published by Messrs. John Bale, Sons and Danielsson, Ltd. In this he will see that I emphasised "stiffness" as one of the most frequently recurring symptoms of aluminium artificially introduced into the system, and that I found this specially affected the back of the neck and head—similar symptoms, in fact, to those he describes in his patient. In the last five years, during which I have been working intensively on this subject from the clinical point of view, I have traced these symptoms in so many patients to aluminium that I can definitely assure Dr. Elwell that this metal was responsible in his particular case.

I am, Sir, yours faithfully,

R. M. LE HUNTE COOPER.

Harley-street, W., Jan. 6th.

* * * Dr. Elwell's patient, who suffered from stiffness and pain in the back of the neck and head, had been in the habit of drinking daily some eight to ten breakfast cups of tea, the water for which was boiled in an aluminium kettle; and the symptoms ceased

when the kettle was no longer used. Dr. Le Hunte Cooper is satisfied from similar experience of his own that aluminium was responsible in Dr. Elwell's case, and he refers to a monograph which he wrote four years ago. At that time we found it difficult to attribute the groups of symptoms he described to the use of aluminium cooking vessels, especially as the work of the American authors whom he quoted in support of his deductions was not confirmed either in the U.S.A. or in this country. Dr. G. W. Monier-Williams, reviewing the subject last year for the Ministry of Health, agreed that there may be individuals who are susceptible even to small doses of aluminium, but found no conclusive evidence that this is so.—ED. L.

BRITISH POSTGRADUATE MEDICAL SCHOOL

THE organisation of the British Postgraduate Medical School provided for a dual teaching staff. There was to be a permanent and whole-time staff, usually referred to as "A staff," and a visiting and part-time staff referred to as "B staff." "B staff" were either to deliver courses of lectures or to take charge of wards for such periods as could be arranged. With the exception of a few lectures in the refresher courses, the whole work of the school since it began has been carried on by "A staff."

With the beginning of the New Year a start will be made with the appointment of members to "B staff." To some extent the method by which the services of "B staff" can be utilised is at present experimental. It will be extended or altered in the light of requirements.

In the department of medicine Lord Horder has agreed to take charge of a ward for a period of ten weeks from Feb. 1st. During this period he will direct the work of the ward with the assistance of the permanent staff, and will conduct two teaching clinics weekly. He will be succeeded by Lord Dawson, who has consented to take charge of beds from May 1st to July 15th. These clinics will be held on Wednesdays and Fridays from 2-4 P.M. In addition, the following courses of lectures have been arranged. Commencing on March 2nd Dr. Gordon Holmes, F.R.S., will give a course of lectures on cerebro-spinal syphilis. Subsequent courses of lectures are to be given by Dr. W. S. C. Copeman on arthritis, and Dr. R. A. Young on non-tuberculous pulmonary diseases.

In the department of surgery Prof. E. W. Hey Groves will commence a series of lectures and demonstrations on fractures on Feb. 7th. These lectures will be given on Fridays commencing at 2.30 P.M. Later in the session Sir James Walton will lecture on the surgical treatment of dyspepsia, Sir Henry Gauvain on surgical tuberculosis, and Mr. Tudor Edwards on thoracic surgery. Each course will consist of about six lectures and will include some practical work as well as demonstrations of cases and of methods of treatment. During the course on surgical tuberculosis visits will be paid to Alton and Hayling Island. Full details of these courses will be published later.

During the absence of Prof. G. Grey Turner at the International Surgical Congress in Cairo Sir Thomas Dunhill and Prof. G. E. Gask are in charge of the surgical wards and the clinical instruction of the school.

Colonel L. W. Harrison has been appointed honorary consultant in venereal diseases at the school.

ROYAL INFIRMARY, BRADFORD.—The board of management intend in the near future to institute a dermatological department at the New Royal Infirmary, Bradford, in connexion with which a new appointment of dermatologist will be made.

INTERNATIONAL SOCIETY OF SURGERY

CAIRO: DEC. 31ST, 1935, TO JAN. 4TH, 1936

(FROM A CORRESPONDENT)

THE eagerly anticipated Tenth Congress really began when two large parties of members embarked on the *Champollion* and the *Mariette Pacha* at Marseilles on Boxing Day. To make contact with friends of other nations, to get to know those whose names are notable in surgery, and to discuss informally problems of mutual interest, is one of the most useful functions of gatherings of this sort; and as sailing conditions were ideal, the opportunity was fully used. In addition a certain amount of committee work was undertaken by the official delegates during the voyage.

The morning of the 30th found us landing at Alexandria, where the British Fleet lay at anchor in the bay. Here our Egyptian hosts took charge of us, and the sight-seeing included a visit to the great new Hôpital Roi Fouad I, situated on the confines of the town and overlooking the Mediterranean. Built of native stone with lavish use of marble, it is after the plan of the Martin Luther Hospital in Berlin and provides for 450 beds, of which 150 are for paying patients. Each of the six floors is painted a different colour and all the wards have hot and cold water, telephones, and wireless. Each of the ward floors has its operating suite with some novel features; but these scarcely seemed to compensate for the poor lighting arrangements. It was interesting to notice that most of the sanitary fittings and equipment had been supplied by British firms. The nurses are all German and everything was spotless.

At Cairo the arrival of about 340 visitors all at the same time rather taxed the resources of some of the hotels, but by midnight most troubles had been smoothed out, lost luggage was restored to rightful owners, and calm reigned once more. Between 8 and 9 next morning the bureau of the Society at the Medical Faculty was besieged and when registration was completed it was found that 392 congressists, not including those from Egypt, were in attendance. With the notable exception of Italy nearly every country in Europe was represented, and there were members from as far afield as Australia, South America, Canada, Malaya, Japan, and China. The Russian Government sent five interested and active members with Dr. Limberg as delegate and leader. One of the members from Finland was on his way to join a Red Cross unit in Abyssinia. Seven members made up the British contingent, while Mr. Gordon-Taylor was expected, en passant, on his way home from the primary fellowship examination in India. Everyone regretted the absence of Prof. Anton von Eiselsberg, who had to forego the presidency for reasons of health.

AN UNCEREMONIOUS OPENING

On the morning of Tuesday, Dec. 31st, the Congress was officially opened in the great hall of the University at Guizeli. This is situated some little distance out of the city and is a beautiful and spacious auditorium which had been finished only the previous evening. As one approached the grand entrance it was obvious that something unusual was afoot, for the vicinity was besieged by hundreds of students distinguished as much by their excitement and volubility as by the picturesque tarbush which they all wear. A sort of catafalque, erected to the memory of students killed in the recent riots, had been erected

just in front of the entrance, and this was the centre of most of the excitement. Early comers reached the hall without much trouble, but late arrivals were considerably jostled and some of the less robust visitors were alarmed. Later the demonstration became noisy; tremendous shouting greeted all new-comers; cars were boarded and the occupants harangued with cries of "Down with England," "Egypt for the Egyptians," &c. Inside the hall while the delegates were assembling on the platform there was an extraordinary incident. A student carrying a large coloured photograph of the students previously killed in the riots mounted the platform and holding the photograph at arm's length called for a two minutes' silence, and then exhorted the large body of students inside the hall who shouted and cheered. It struck the visitors as remarkable that all this was allowed to take place without the slightest interference from the police or officials of any sort. Eventually Prince Mohamed Aly Hassan with his suite arrived and occupied the Royal Box, after which the ceremony was allowed to proceed without much interruption, although the departing guests, and especially those on foot, had to run the gauntlet amid a vociferous mob yelling and shouting.

But these incidents did not upset the Congress in any way. As president of the organising committee, the Minister of Public Instruction welcomed the visitors in an appropriate speech in French, which was thoughtfully circulated in that language and in Egyptian. ALY IBRAHIM Pasha spoke as the dean of the faculty, while Dr. VEREOOGEN (Brussels), chairman of the international committee, Prof. DE QUERVAIN (Berne), past-president, Dr. MAYER (secretary-general of the Society), and Dr. SCHOE-MAKER (The Hague), the president, all made speeches outlining the work and the activities of the Society.

SURGERY OF THE PARATHYROIDS

After the excitement of the morning the first scientific session, held at two o'clock in the afternoon, was somewhat of a relief. The subject was the surgery of the parathyroids, and the reports of the openers BINET (Paris), BAUER (Breslau), and BRAINE and CHIFOLIAN (Paris) were succinct and admirable. Among the supporters LERICHE (Strasbourg) contrasted operations on the parathyroids with those on the sympathetic, and also referred to the importance of the possible consequences from interference with the blood-supply of the glands. His remarks were received with acclamation. JIRASEK (Prague) and HABERLAND (Cologne) made suggestive contributions, and HUSSEIN (Cairo) focused on the difficulty of the subject by comparing the problem with that of the nine blind men describing the elephant! PERERA Y PRATS (Madrid) suggested that in Recklinghausen's disease of bone removal of the parathyroid was definitely indicated, in scleroderma it was useless, in polyarthritis it was of very doubtful value, while in Glénard's disease and muscular asthenia it was to be considered on its trial. In this discussion PLOTKIN (Moscow) also took part.

THE SURGICAL SIGHTS OF CAIRO

On New Year's morning visits were paid to the departments of the medical school and to the hospitals. Among the former the anatomical and the pathological departments were found most interesting. Prof. Bernard Shaw is developing a very complete department in pathology with many new features. From about 200 autopsies a year he is building up complete reports with preservation of the naked-eye specimens and histological slides all

indexed and filed for subsequent study. The museum of the department is already wonderfully complete, and the series of case specimens and specimens with clinical, X ray, and microscopical records was of great teaching value.

The work in the operating theatres of the Kasr-el-Aini Hospital was varied and interesting. Egyptian surgeons have a unique experience of splenectomy and of the complications of bilharzia. Examples of both conditions were dealt with skilfully and with proper restraint. The frequency of the Egyptian splenomegaly is almost certainly due to intestinal infection which is very common in this country. The results have much improved since it has become the practice to spend three or four weeks in preliminary treatment and to operate only when the enlarged spleen is an encumbrance and danger from its size and liability to injury. In one series of several hundred operations the mortality was 12 per cent., and in a recent consecutive series of 30 cases there was no death. One surgeon at another hospital carried out six splenectomies the same morning. Silk or linen thread is used for the pedicle. Provided that concomitant disease has been conquered the late results are very encouraging.

The Kasr-el-Aini Hospital is really a fifteenth century building which for many years was the palace of the governors. After the conquest of Napoleon it was made into a hospital with Baron Larrey as chief surgeon. In recent years it has been altered and renovated, and with its 1500 beds it serves the purposes of a modern hospital very well. The wards are clean and bright, and the thick walls of the old palace and the wide central corridors help to keep them cool in summer. To the visitor unaccustomed to Eastern conditions the way in which the patients squat on the beds and other unusual attitudes are rather remarkable, but they seemed wonderfully content and we were informed that they make good patients and, generally speaking, put up an excellent resistance at least to operations and traumatisms. The senior nurses are all British-trained, but an additional nursing staff of Egyptian girls is being recruited. The new hospital on the Island is making rather slow progress, but the new out-patient department is now complete and is remarkably efficient. It deals with enormous numbers and on the day before our visit there were 3457 attendances of which over 800 were new patients.

LUMBAR SYMPATHECTOMY

On Thursday the scientific session began just after 8 A.M., the subject for discussion being lumbar sympathectomy. BRAENCKER (Hamburg) gave an excellent presentation of the anatomy, illustrated by some beautiful slides. LERICHE (Strasbourg) followed, and his well-known interest in this subject led him to treat of the related pathology of occlusive arterial diseases. GONZALEZ AGUILAR (Santander) suffered from the fact that few of the congressists seemed to understand Spanish. YOUNG (Glasgow) made a plea for the consideration of periarterial sympathectomy in properly selected cases, and LAMBERT ROGERS (Cardiff) made an effective contribution on clinical and anatomical grounds. Many of the speakers quoted experimental work in which arteriography had played a useful part.

There were so many communications that the discussion had to be postponed until Saturday afternoon.

SURGERY OF THE COLON

Friday's discussion was opened by CORACHAN (Barcelona), GREY TURNER (London), SOUPAULT

(Paris), and SCHOEMAKER (The Hague). There were no less than 52 names down as subsequent speakers, but, perhaps fortunately, only 19 actually turned up. For the most part the openers gave a general review of the subject, reflecting the practice of their several countries. There seemed to be unanimity about the wisdom of a suitable regimen for uncomplicated diverticulosis, operative treatment being reserved for the complications. DE QUERVAIN (Berne) caused amusement by suggesting that diverticulosis seemed peculiarly liable to occur in diplomats! JIRASEK (Prague) spoke in excellent English and made his points very clearly. He stated that in non-malignant disease a permanent spasm of the distal part of the bowel was prone to follow an unphysiological colostomy. HABERLAND (Cologne), speaking in German, was equally explicit, and drew attention to a new form of suture for the colon. SHELTON HORSLEY (Richmond, Va.) showed some interesting lantern slides. He stressed the value of multiple stage operations in colonic resection, and spoke of the use of continuous intravenous infusions of 5 per cent. dextrose in Ringer's solution and the preliminary use of vaccines. LEVEUF (Paris) gave a clear exposition of the value of colectomy for aggravated colitis, and reported some very good results. FINSTERER (Vienna) was listened to with great attention while he related the results of a fine series of partial colectomies which he had carried out for spastic and other conditions of the great bowel. The results of hemisection, whether right or left, had been most satisfactory, but total colectomy had proved dangerous and unsatisfactory in his hands. One speaker (GREY TURNER) hit upon the idea of projecting short epitomes in the French language under each of his headings—these were interspersed between ordinary slides showing specimens, and seemed to be a satisfactory method of overcoming some part of the language difficulty.

THE END OF THE CONGRESS

On Saturday, from 8 to 12, we are promised a full programme of lantern demonstrations and the like under the auspices of a special meeting of the Egyptian Medical Society. The afternoon, from 2 to 6, is reserved for presentations and reports on bilharzia by ALY IBRAHIM Pasha, dean of the medical faculty, and NAGUIB MAKAR, both of Cairo, and a large number have signified their intention to take part in the discussion. As though that were not enough any discussion postponed from previous sessions is then to be dealt with!

Our hosts have been most hospitable, and every night save one there have been banquets or receptions. The banquet of closure on Saturday, given by the Egyptian surgeons, will really be a welcome end to a strenuous though happy and useful week.

The social side of the Congress has been well arranged, and besides the evening functions, like the President's reception at the magnificent Palace Hotel in Heliopolis, trips on the Nile to the Barrages of the Delta and, of course, an excursion to the Pyramids, were thoroughly enjoyable. All the "sights" of Cairo seemed to be open on presentation of the membership card, and we were met by kindness and cordiality on every side. All who participated in this successful congress must be grateful to Dr. Aly Ibrahim Pasha and his able secretaries, Dr. M. Khalil Bey and Dr. M. Kamel Hussein.

WORK OF THE INTERNATIONAL SOCIETY

There have been long meetings of the international committee to discuss several problems connected

with the future of the Society. The propositions put forward were to create associate members with all the privileges of the Society but without voting power up to 50 per cent. of the titular members of each country, and to establish a journal to be published every two months in order to keep up the interest of the members in the affairs of the Society between the triennial meetings. On account of the fall in value of the franc the subscription for future members is to be raised to 450 Belgian francs. These propositions were later brought before the general assembly and adopted—but not without some opposition regarding the new journal, because many members felt that there were already more than enough.

Invitations for the next congress were received from Russia, Switzerland, and Austria, and it was eventually decided to hold the next congress in Vienna in 1938 under the presidency of Dr. Rudolph Matas of New Orleans. Prof. Sauerbruch (Berlin) and Dr. Hybbinette (Stockholm) were elected vice-presidents, while the re-election of the treasurer, Dr. Lorthioir, and the urbane and indefatigable secretary, Dr. L. Mayer, were received with acclamation. The subjects selected for discussion at the next congress were (1) the surgery of arterial hypertension, (2) bone-grafting, and (3) tumours and cysts of the lung.

The name of Prof. Lambert Rogers, of Cardiff, was added to the British committee.

PUBLIC HEALTH

Grading of Milk by the Total Bacterial Count

In the *Medical Officer* of Dec. 28th Dr. J. B. Howell writes of the unreliability of grading milk according to the total bacterial count and the test for coliform organisms. He finds that if he sends identical samples to different laboratories for total bacterial counts the reports are often quite different. In one extreme case (already quoted in our columns 1934, ii., 1074) two identical samples sent to the same laboratory produced counts of 147,300 and 3,400,000 per c.cm., while a different laboratory receiving a third sample reported that the content was only 9270 per c.cm.

Anyone with experience of total bacterial counts on milk will not be much surprised at such results; it is common knowledge that the total count technique, which is based upon the unwarranted assumption that every colony originates from a single organism, is full of pitfalls. But Dr. Howell is hardly being fair when he assumes that variations in count are due to the failure of bacteriologists to "faithfully and carefully carry out the suggested procedure." The factor which probably has most effect on the bacterial content of milk is the state of the weather, which is altogether outside the bacteriologist's control. In hot weather bacteria grow extremely rapidly in milk, and unless samples are transported from the sampler to the laboratory packed in an efficient ice-box there may be big variations in bacterial growth within a short period of transit, depending upon the different temperatures attained. Apart from considerations of temperature, it is extremely hard to standardise a test of this type. There are mechanical faults such as errors in the graduation of pipettes to be controlled; there are the difficulties of standardising culture medium prepared from such variable constituents as meat and peptone; and there is a difficulty to which Dr. Howell draws attention—that of breaking up cell aggregates in the milk. This is attempted by shaking the sample in a bottle; but it is impossible to disintegrate all clumps and chains of organisms suspended in milk, and any endeavour to standardise the degree of disintegration by standardising the amount and method of shaking will achieve but slight success. Finally, in preparing total counts the failure of the human element plays an important part, both during the various manipulations and in the final counting. However well-trained and conscientious laboratory technicians may be, their errors cannot be reduced to a level at which they can be ignored.

Undoubtedly there are strong grounds for agreeing

with Dr. Howell that little reliance can be placed upon a report of the bacterial content of a milk when judging the grade or quality of a sample. Comparison of a series of counts made at frequent intervals enable one to form a reasonable estimate of the standard of cleanliness under which the milk has been produced, but the results of a single test are usually worthless.

Generally speaking, two fundamental objections can be levelled against the present method of grading milk. The one is based upon the inherent inaccuracies of the total count; the other is that owing to the laboratory accommodation necessary, and the high degree of technical skill required, for performing the count a very definite economic limit is set to the number of times an individual milk-supply can be tested in the course of a year. Obviously, therefore, an improved method of grading milk depends not upon improving or elaborating the technique of the total count, but rather upon devising a test simple and cheap enough to be applied to an individual supply of milk—daily if need be—and one which eliminates some of the above inaccuracies.

We may look for some further light on choice of technique when Prof. G. S. Wilson's expected report is issued. In the meantime reference should be made to the method of judging the quality of milk for pasteurisation, which was first suggested by Anderson and Meanwell,¹ and is also advocated in a report by Scott and Wright² which has just reached us. Bacterial counts are made of the milk before and after pasteurisation and the results are correlated, attention being chiefly paid to the post-pasteurisation count. It has been shown that while the pre-pasteurisation count is largely influenced by weather conditions and may be a very unreliable index of the hygienic conditions of the farm, the post-pasteurisation count of heat-resistant organisms depends largely upon the cleanliness of production, these organisms coming mainly from badly sterilised apparatus.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
DEC. 28TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2052; diphtheria, 997; enteric fever, 20; acute pneumonia (primary or influenzal), 1076; puerperal fever, 35; puerperal pyrexia, 72; cerebro-spinal fever, 14; acute poliomyelitis, 8; encephalitis

¹ Anderson, E. B., and Meanwell, L. J.: *Jour. Dairy Research*, 1933, iv., 213.

² Scott, A. W., and Wright, N. C.: *Hannah Dairy Research Inst. Bull.*, No. 6, 1935.

lethargica, 5; dysentery, 33; ophthalmia neonatorum, 42. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 3rd, 1936, was 3728, which included: Scarlet fever, 1164; diphtheria, 1212; measles, 315; whooping-cough, 465; puerperal fever, 19 mothers (plus 14 babies); encephalitis lethargica, 279; poliomyelitis, 3. At St. Margaret's Hospital there were 14 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 39 (3) from measles, 4 (1) from scarlet fever, 28 (7) from whooping-cough, 40 (6) from diphtheria, 59 (20) from diarrhoea and enteritis under two years, and 80 (14) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza, of which the total has begun to rise, is scattered over 47 great towns, Liverpool reporting 5, Manchester 4, Bolton and Leicester each 3, no other great town more than 2. Liverpool reported 15 deaths from measles, Manchester 7, Warrington 3. Liverpool also had 5 deaths from whooping-cough. The deaths from diphtheria were reported from 24 great towns: Liverpool 5, Darlington, Manchester, Newcastle-on-Tyne, Sheffield, Wallasey, Warrington, and Birmingham each 2.

The number of stillbirths notified during the week was 233 (corresponding to a rate of 60 per 1000 total births), including 31 in London.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

THURSDAY, Jan. 16th.—8.15 P.M., Col. C. A. Gill: Some Points in the Epidemiology of Malaria, arising out of the Malaria Epidemic in Ceylon.
- PADDINGTON MEDICAL SOCIETY.**
TUESDAY, Jan. 14th.—9 P.M. (Great Western Royal Hotel, W.) Mr. G. G. Turner: Income-tax in Medical Practice.
- TUBERCULOSIS ASSOCIATION.**
FRIDAY, Jan. 17th.—5.15 P.M. (Manson House, 26, Portland-place, W.) Dr. Noel Bardswell, Dr. J. G. Johnstone, and Miss M. C. Marx: After-care of the Tuberculous in London. 8.30 P.M., Dr. James Maxwell: Intestinal Tuberculosis.
- BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck-street, W.**
THURSDAY, Jan. 16th.—7.45 P.M., Special General Meeting. 7.45 P.M., Dr. J. F. Brailsford: Radiological Demonstration of Developmental Abnormalities of the Skeleton.
- FRIDAY.—11 A.M., Visit to the X Ray Department of St. Mary's Hospital. 5 P.M., Case Demonstration and Discussion. (Medical Meeting.)

- NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY, Royal Northern Hospital, N.**
WEDNESDAY, Jan. 15th.—9 P.M., Dr. Bellingham Smith: Continued Fever.
- SOCIETY FOR THE STUDY OF INEBRIETY.**
TUESDAY, Jan. 14th.—4 P.M. (11, Chandos-street, W.) Dr. W. Norwood East and Dr. H. J. Norman: The Relations of Alcoholism and Crime to Manic-depressive Disorder.
- BIOCHEMICAL SOCIETY.**
FRIDAY, Jan. 17th.—3 P.M. (United Dairies Research Laboratories, Wood-lane, W.1), Short Communications.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

- ROYAL COLLEGE OF SURGEONS, Lincoln's Inn-fields, W.C.**
FRIDAY, Jan. 17th.—5 P.M., Prof. A. F. MacCallan: The Surgery and Pathology of Trachomatous Conjunctivitis. (Hunterian Lecture.)
- UNIVERSITY COLLEGE, LONDON.**
THURSDAY, Jan. 16th.—5 P.M., Mr. F. G. Young, Ph.D.: Glycogen and the Metabolism of Carbohydrates. First of four lectures.
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.**
WEDNESDAY, Jan. 15th.—2 P.M., Dr. R. S. Frew: Cough. 3 P.M. Dr. A. Signy: Prophylaxis of Whooping-cough and Measles.
Out-patient Clinics daily at 10 A.M. and ward visits (except on Wednesday) at 2 P.M.
- LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.**
TUESDAY, Jan. 14th.—5 P.M., Dr. G. B. Dowling: Pityriasis Dermatitis.
WEDNESDAY.—5 P.M., Dr. I. Muende: Histopathology of Some Common Skin Diseases.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**
MONDAY, Jan. 13th, to SUNDAY, Jan. 19th.—ST. JOHN'S HOSPITAL, 5, Lisle-street, Leicester-square, W.C. Afternoon Course in Dermatology. (Open to non-members.)—NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W. All-day Course in Cardiology. (Open to non-members.)—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. Tues., 8.30 P.M., Mr. McNeill Love: Hernia. Thurs., 8.30 P.M., Mr. A. Lawrence Abel: The Surgery of the Sympathetic Nervous System.—ROYAL CHEST HOSPITAL, City-road, E.C. Sat. and Sun., Course in Diseases of the Heart and Lungs. (Open to non-members.)—(Courses arranged by the Fellowship are open only to Members.)
- LEEDS GENERAL INFIRMARY.**
TUESDAY, Jan. 14th.—3.30 P.M., Dr. MacAdam: Some Cases of Minor Invalidism.
- LEEDS PUBLIC DISPENSARY AND HOSPITAL.**
WEDNESDAY, Jan. 15th.—4 P.M., Mr. L. N. Pyrah: Injection Therapy in the Treatment of Hemorrhoids, Varicose Veins, and Hydrocele.
- UNIVERSITY OF DURHAM.**
SUNDAY, Jan. 19th.—10.30 A.M. (Newcastle General Hospital), Prof. T. Beattie: Medical Ward Visit.
- GLASGOW POST-GRADUATE ASSOCIATION.**
WEDNESDAY, Jan. 15th.—4.15 P.M. (Royal Maternity and Women's Hospital), Prof. James Hendry: Hemorrhage at the End of Pregnancy.

Appointments

- ATLEE, C. N., M.D. Durh., M.R.C.P. Lond., D.P.H., D.P.M., has been appointed Divisional Medical Officer to the London County Council.
- BALDWIN, E. J., M.B. Oxon., D.O.M.S., Hon. Ophthalmic Surgeon to the Essex County Hospital, Colchester.
- LAURENT, L. P. E., M.D., M.R.C.P. Lond., Medical Registrar at the West London Hospital.
- MITMAN, M., M.D., M.R.C.P. Lond., D.P.H., D.M.R.E., Medical Superintendent, Eastern Hospital.
- PEET, E. W., M.B. Durh., F.R.C.S. Eng., Bernhard Baron Research Student at the Ferens Institute of Otolaryngology at the Middlesex Hospital Medical School.
- SYKES, RUPERT, M.D., M.R.C.P. Lond., Resident Medical Officer at the Manchester Royal Infirmary.
- TALBOT, G. G., M.B. N.Z., F.R.C.S. Eng., Second Ophthalmic Surgeon to the Royal Northern Hospital, N.7.
- THOMPSON, H. R., M.B. Camb., F.R.C.S. Eng., Surgical First Assistant and Registrar at the London Hospital.
- WALTON, W. S., M.D. Durh., B.Hy., D.P.H., Medical Officer of Health and School Medical Officer for West Bromwich.
- WYATT, WALTER, M.B. Edin., L.D.S., D.P.M., Assistant School Medical Officer in Leeds.
- Princess Alice Memorial Hospital, Eastbourne.*—The following appointments are announced:—
HALL, E. WILSON, F.R.C.S. Edin., Hon. Surgeon;
SHERWOOD, G. D., M.B. Camb., Hon. Surgeon;
CROOK, A. H., M.Chir. Camb., F.R.C.S. Eng., Surgeon in Charge of Fracture Clinic;
ESTCOURT, H. G., M.B. Lond., F.R.C.S. Edin., Hon. Assistant Surgeon;
WILSON, T. H., M.B. Lond., F.R.C.S. Eng., Hon. Assistant Surgeon.

MEDICAL NEWS

University of Cambridge

The Rockefeller Foundation have made an annual grant of not more than £1200 for five years for research in cellular physiology at the Molteno Institute under the direction of Prof. Keilin.

The title of the degree of M.B. has been conferred on Mrs. M. H. D. Gunther.

University of London

At recent examinations the following candidates were successful:—

M.D.

Branch I. (Medicine).—W. H. P. Cant, Univ. of Birm.; P. C. L. Carrier, Charing Cross Hosp.; Iris M. Cullum, Royal Free Hosp.; M. E. Disney, London Hosp.; T. J. Evans, Univ. Coll. Cardiff, and Middlesex Hosp.; S. T. Falla, London Hosp.; H. F. M. Finzel, Univ. of Brist.; Clifford James, Middlesex Hosp.; D. E. V. Jones, King's Coll. Hosp.; H. M. R. Jones, Middlesex Hosp.; Herbert Kirman, King's Coll. Hosp.; Beatrice Lewis, Univ. Coll. Hosp.; R. J. G. Morrison, St. Bart.'s Hosp.; Ivor Whittington, St. George's Hosp.; J. C. Winteler, King's Coll. Hosp.; and Tamsin M. Wynter, Royal Free Hosp.

Branch II. (Pathology).—Ronald Hare, St. Mary's Hosp.; W. A. E. Karunaratne, Univ. Coll. Hosp.; D. M. Pryce, St. Mary's Hosp.; and R. S. Wale, King's Coll. Hosp.

Branch III. (Psychological Medicine).—H. A. Cooper, King's Coll. Hosp.

Branch IV. (Midwifery and Diseases of Women).—R. K. Bowes, Univ. of Liverp. and St. Thomas's Hosp.; J. O. F. Davies, Middlesex Hosp.; Mary Evans, King's Coll. Hosp.; and Margaret M. White and Honor E. C. Wilkins, Royal Free Hosp.

Branch V. (Hygiene).—D. M. Connan, King's Coll. Hosp. and Westminster Hosp.; David Erskine, Guy's Hosp. and London School of Hygiene and Tropical Medicine; J. T. R. Lewis, Middlesex Hosp.; and F. J. G. Lishman, Univ. Coll. Hosp. and London School of Hygiene and Tropical Medicine.

University of Birmingham

At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B., B.S.

E. M. Barker, Dorothy M. Braddock, N. R. Chan-Pong, A. W. F. Craig, F. J. Fowler, R. J. Ingham, E. E. K. Kilvert, B. A. Singer, Aileen M. Sutcliffe, and L. K. Thompson.

B.D.S.

C. G. Heils.

Royal College of Surgeons of England

The following lectures will be given at the college on Mondays, Wednesdays, and Fridays from Jan. 17th to Feb. 21st: Jan. 17th, Mr. A. F. MacCallan, the surgery and pathology of trachomatous conjunctivitis; Jan. 20th, Dr. E. W. Twining, a radiological study of the third ventricle; Jan. 22nd, Mr. Arthur Bulleid, the assessment of dental sepsis as a factor affecting medical and surgical procedures; Jan. 24th, Mr. John Gilmour, adolescent deformities of the acetabulum; Jan. 27th, Mr. E. P. Stibbe, the anatomy and surgery of the subtentorial angle; Jan. 29th, Mr. R. T. Payne, pyogenic infections of the parotid; Jan. 31st, Mr. G. A. Mason, extirpation of the lung; Feb. 3rd, Mr. A. M. Boyd, the investigation of peripheral vascular disease; Feb. 5th, Mr. H. Osmonde Clarke, injuries of the carpal bones; Feb. 7th, Mr. F. H. Bentley, wound healing in vitro and the interrelation of epithelial and fibrous tissue growth; Feb. 10th, Mr. G. C. Knight, intestinal strangulation; and Feb. 12th, Mr. G. F. Rowbotham, a series of tumours of the skull. On Feb. 17th, 19th, and 21st Dr. John Beattie will give three lectures on temperature regulation. All the lectures will take place at 5 P.M.

Order of St. John of Jerusalem

The following promotions in and appointments to the Venerable Order of the Hospital of St. John of Jerusalem have been sanctioned by the King:—

As Knight of Grace.—Lieut.-Colonel R. E. Wodehouse, O.B.E., M.D.

As Commander.—James Cairns, O.B.E., M.B., and Lieut.-General Sir James Andrew Hartigan, K.C.B., C.M.G., D.S.O., M.B.

As Officer.—Dr. N. M. Goodman, Major C. G. H. Morse, M.R.C.S.; Major R. F. Walker, M.C., M.B., R.A.M.C.; Dr. A. Tetreault, Lieut.-Colonel J. N. Gunn, D.S.O., M.D., M.R.C.S.; and Mrs. Constance E. M. Berridge, M.B.

Royal Society of Arts

On Wednesday, Jan. 15th, at 8 P.M., Mr. L. H. Lampitt, D.Sc., chairman of the food group of the Society of Chemical Industry, will speak on Food and the World.

Guild of Hospital Librarians

The first international meeting of this guild will be held in Paris from May 8th to 11th. The speakers will include Dr. René Sand, Madame Getting, Mademoiselle Oddon, Mr. C. E. A. Bedwell, Mrs. M. E. Roberts, and Mr. A. D. Power. The hon. secretary may be addressed at 48, Queen's-gardens, London, W. 2.

Hunterian Society

The Hunterian lecture of this society will be delivered at the Mansion House, London, E.C., at 9 P.M. on Monday, Jan. 20th, by Dr. Sven Ingvar, professor of medicine at the University of Lund, Sweden. He will speak on the physical basis of psychoneurosis.

The annual dinner of the society will be held on Thursday, Feb. 13th, at the May Fair Hotel.

Post-graduate Work in Newcastle

Under the auspices of the University of Durham classes will meet at the Babies' Hospital and Royal Victoria Infirmary, Newcastle, during the months of January, February, and March on Thursday afternoons. Till March 22nd there will be lecture demonstrations in medicine and surgery every Sunday at 10.30 A.M. Further particulars may be had from the Registrar, College of Medicine, Newcastle-upon-Tyne.

The late Dr. Haydn Brown

The death occurred on Jan. 3rd of Dr. Haydn Brown at his house in Bedford-square. He came prominently before the public as on two occasions the General Medical Council felt constrained to remove his name from the Medical Register for ethical reasons, which led to journalistic comment. He wrote profusely on many subjects which, generally speaking, fall within the province of the neurologist, but he was unable to convince his medical colleagues of the scientific soundness of his theories, in which he himself was, however, an implicit believer.

German Society for Internal Medicine

The Deutsche Gesellschaft für Innere Medizin is holding its forty-eighth meeting from March 23rd to 26th at Wiesbaden under the presidency of Prof. Schwenkenbecher of Marburg. A joint meeting will be held with the Reichsarbeitsgemeinschaft für eine neue deutsche Heilkunde when the internal treatment of thyrotoxicosis will be discussed. Other subjects for discussion will be the electrocardiographic diagnosis of myocarditis and diseases of the lung caused by inhalation of dust. The last two sessions will be devoted to joint meetings with the Deutsche Röntgengesellschaft when the subjects of discussion will be inflammatory diseases of the large intestine, the diagnosis of cavities, and the radiotherapy of malignant tumours of the internal organs. Dr. A. Géronne, of Wiesbaden, is the secretary of the congress.

The Medical Society of London

The second half of the 1935-36 session of this society will open on Jan. 13th with a pathological meeting. On Jan. 27th Mr. Zachary Cope will open a discussion on the treatment of acute appendicitis, and other discussions and their openers will be: Mr. C. S. Lane-Roberts on the treatment of sterility (Feb. 10th), Lord Horder on the aetiology and treatment of *B. coli* infections of the urinary tract (Feb. 24th), Mr. A. Dickson Wright on phlebitis and its treatment (March 9th), and Prof. G. Grey Turner on surgery of the oesophagus (March 23rd). The Lettsoman lectures will be given on Feb. 10th and 26th and March 2nd by Dr. Philip Manson-Bahr, who has chosen as his subject the differential diagnosis of diseases of the colon (dysentery and colitis) and their complications, with special reference to treatment. Sir James Walton will deliver the annual oration on May 11th, when he will speak on carcinoma of the stomach. The annual dinner of the society will be held at Claridge's on Thursday, Feb. 27th.

Pharmaceutical Society of Great Britain

On Tuesday, Jan. 14th, Mr. H. Berry will give a lecture on sterilisation technique. The meeting will be held at 8.30 p.m. at the house of the society, 17, Bloomsbury-square, London, W.C.

Tenth British Congress of Obstetrics and Gynaecology

This Congress will be held at Belfast from April 1st to 3rd under the presidency of Prof. R. J. Johnstone. One of the chief subjects of discussion will be the conservative treatment (operative or otherwise) of pathological conditions of the ovaries, tubes, and uterus, and there will be communications from several sources on radiotherapy of uterine diseases, on the use of sex hormones in gynaecology, and on sepsis and other complications of pregnancy and labour. The secretaries are Mr. C. H. G. Macafee and Dr. F. M. B. Allen, and the address of the former is 18, University-square, Belfast.

A Drowning Tragedy

Further details are to hand of the death of Dr. A. B. Aitken, which occurred on Dec. 8th at Lagos, as a result of a drowning accident. Dr. Aitken, who received his medical education at the University of Glasgow and the London Hospital, graduated as M.B., Ch.B. Glasg. in 1905 and took the diploma of F.R.C.S. Eng. in 1909. He served as house surgeon to the Royal Hospital for Sick Children, Glasgow, and at the outbreak of war, with the rank of temporary captain, was attached to the R.A.M.C. as a surgical specialist. Later he became consulting surgeon to the African hospital at Lagos and established a reputation throughout the whole district as a surgeon. He was out swimming with a party at Lagos when he got into difficulties. A brave attempt to rescue him was made by Sir Walter Johnson, director of medical and sanitary services in Nigeria, who himself was only saved by means of a rope of towels knotted together by other members of the party.

B.M.A. Scholarships and Grants in Aid of Research

The Council of the British Medical Association is prepared to receive applications for research scholarships and grants for the assistance of research in connexion with disease.

Scholarships.—An Ernest Hart Memorial Scholarship, value £200 per annum, a Walter Dixon Scholarship, value £200 per annum, and three Research Scholarships, each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Each scholarship is tenable for one year, commencing on Oct. 1st, 1936. A scholar may be reappointed for not more than two additional terms and is not necessarily required to devote whole time to the work, but may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointment do not interfere with the work as a scholar.

Grants for the assistance of research into the causation, treatment, or prevention of disease will be made to applicants who propose as subjects of investigation problems directly related to practical medicine.

In making awards preference will be given to members of the medical profession, and applications must be made not later than May 9th on the prescribed form, a copy of which will be supplied on application to the medical secretary of the Association, B.M.A. House, Tavistock-square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Vacancies

For further information refer to the advertisement columns

Aberdeen City District Mental Hospital.—Jun. Asst. M.O. £300.
Bury Surgical Hospital.—Res. Surg. O. £350.
Bedford County Hospital.—Second H.S. At rate of £150.
Birmingham City Mental Hospital.—Jun. Asst. M.O. £350.
Birmingham and Midland Eye Hospital.—Res. Surg. O. £200.
Birmingham, Selly Oak Hospital.—Jun. M.O.'s. Each at rate of £200.
Birmingham United Hospital.—Bacteriologist and Clin. Pathologist. £500.
Bolingbroke Hospital, Wandsworth Common, S.W.—H.P. At rate of £120.

Boole General Hospital.—H.P., two H.S.'s. Also Cas. O. Each at rate of £150.
Brighton, Sussex Eye Hospital.—Hon. Asst. Surgeon.
Bristol Royal Infirmary.—H.P.'s, H.S.'s, &c. Each at rate of £80. Also Sen. Obstet. Surg. At rate of £100.
British Postgraduate Medical School, Ducane-road, W.—H.P. Carshalton, Surrey, *Queen Mary's Hospital for Children.*—Asst. M.O. £250.
Charing Cross Hospital, W.C.—Hon. Anaesthetist.
Chelsea Hospital for Women, Arthur-street, S.W.—Pathologist. £40.
Colchester, Essex County Hospital.—Asst. H.S. £120.
Colindale Hospital, Colindale, N.W.—Asst. M.O. £350.
County Hall, Westminster Bridge, S.E.—Asst. M.O. £600. Also Asst. M.O.'s for School Medical Work. 30s. a session.
Coventry and Warwickshire Hospital.—H.S. to Aural and Ophth. Depts. At rate of £125.
Croydon, Mayday Hospital.—Jun. Res. Asst. M.O. £300.
Doncaster Royal Infirmary.—H.S. £175.
Doncaster County Council.—Asst. County M.O. £500.
Eastern Fever Hospital, Homerton-grove, E.—Asst. M.O. £250.
East Riding Mental Hospital, Beverley.—Jun. Asst. M.O. £250.
Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Clin. Asst. to Far, Nose, and Throat Dept. Also Asst. Radiologist. £100.
Evelina Hospital for Sick Children, Southwark, S.E.—Dental Surgeon. 50 guineas.
Glasgow Victoria Infirmary.—Asst. Radiologist. Also two additional Visiting Anaesthetists. Each £400.
Grimby and District Hospital.—Sen. H.S. £200. Also Jun. H.S. and H.P. Each £150.
Halifax General Hospital.—Jun. Res. M.O. £250.
Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.—H.P. At rate of £100.
Hertford County Hospital.—H.P. At rate of £150.
Huddersfield County Borough.—Asst. School M.O. £500.
Ipswich, East Suffolk and Ipswich Hospital.—H.P. £144.
Ipsworth, West Middlesex County Hospital.—Res. Anaesthetist. £400. Also Cas. M.O. £350.
Kettering and District General Hospital.—Second Res. M.O. At rate of £125.
Leeds General Infirmary.—Res. Aural Officer. £149.
Liverpool and District Hospital for Diseases of Heart.—H.P. At rate of £100.
Liverpool, Royal Children's Hospital.—Med. Reg. and Tutor. £50.
Liverpool, Stanley Hospital.—H.S., H.P., and Gynaecological H.S. Each at rate of £100.
L.C.C. Group Laboratory, Archway Hospital, Archway-road, N.—Asst. Pathologist. £650.
London County Council.—Asst. M.O.'s for Mental Hospital. Each £170.
London Homoeopathic Hospital, Great Ormond-street, W.C.—Asst. Physician for Diseases of Women.
London Hospital, E.—Asst. in X Ray Dept. £100. Also Hon. Asst. Surgeon.
London School of Clinical Medicine, Dreadnought Hospital, Greenwich, S.E.—Jun. Pathologist. £400.
Manchester, Ancoats Hospital.—Two H.S.'s. Each at rate of £100. Also Med. Reg. £50.
Manchester Victoria Memorial Jewish Hospital, Cheetham.—Res. H.S. £150.
Marie Curie Hospital, 2, Fitzjohns-avenue, N.W.—Res. M.O. At rate of £100.
Metropolitan Hospital, Kingsland-road, E.—Res. Cas. O. £100.
National Dental Hospital.—Hon. Asst. Anaesthetist.
Newcastle-upon-Tyne, Barrasford Sanatorium.—Res. Med. Asst. £250.
Newcastle-upon-Tyne, City Hospital for Infectious Diseases.—Res. Med. Asst. £350.
Newcastle-upon-Tyne, Hospital for Sick Children.—Res. Surg. O. £250. Also H.P. and H.S. Each at rate of £100.
Nottingham General Hospital.—H.S. At rate of £150.
Oswestry, Robert Jones and Agnes Hunt Orthopaedic Hospital.—H.S. At rate of £200.
Pinewood Sanatorium, Wokingham, Berks.—Asst. M.O. £250.
Plymouth, Mount Gold Orthopaedic and Tuberculosis Hospital.—Asst. Res. M.O. £350.
Preston, Biddulph Grange Orthopaedic Hospital.—Sen. H.S. At rate of £250.
Putney Hospital, Lower Common, S.W.—Jun. M.O. At rate of £100.
Queen's Hospital for Children, Hackney-road, E.—Three Anaesthetists. One guinea per attendance.
Reading, Royal Berkshire Hospital.—Cas. O. At rate of £125.
Royal Eye Hospital, St. George's-circus, Southwark, S.E.—Hon. Asst. Surgeon.
Royal Masonic Hospital, Ravenscourt Park, W.—Surgeon.
St. Bartholomew's Hospital, E.C.—Asst. Physician. Also Asst. Physician and Asst. Director to Medical Professorial Clinic.
St. Mary's Hospital, W.—Cas. H.S. At rate of £100.
Salford Royal Hospital.—Orthopaedic Reg. £100.
Smethwick, St. Chad's Hospital.—Res. Obstet. Officer. £350. Also Jun. Res. M.O. At rate of £150.
Southampton, Borough General Hospital.—Jun. Res. M.O. £200.
South London Hospital for Women, Clapham Common, S.W.—Out-patient M.O. £100.
Stockport Infirmary.—Res. Surg. O. £250.
Stoke-on-Trent, Longton Hospital.—H.S. £160.
Swindon and North Wills Victoria Hospital.—Second Res. M.O. £125.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Cas. O. At rate of £200. Also H.P. and H.S. Each at rate of £100.
West End Hospital for Nervous Diseases, Gloucester-gate, N.W.—Res. H.P. £125.
Westminster Hospital, Broad Sanctuary, S.W.—Asst. Obstet. Surgeon.
Worcester Royal Infirmary.—Jun. H.S. £120.
Workson, Victoria Hospital.—Sen. and Jun. Resident. At rate of £150 and £120 respectively.

NOTES, COMMENTS, AND ABSTRACTS

SCHOOL PRESSURE IN WORK AND PLAY

THAT the stress of modern education and examinations in schools is shown by a loss of weight during term, the weight being made up in holidays. was the contention of Dr. G. O. Barber, M.O., of Felsted, who opened a discussion at a meeting of the Society of Medical Officers of Schools, held at University College on Jan. 3rd. The fact that this rhythm occurred in day- as well as in boarding-schools showed that it was not due to school food. It was, moreover, general experience that a boy admitted to the sanatorium with some minor physical injury slept solidly, waking only for food, for the first 24 hours. Similarly children slept a lot at the beginning of the holidays before they came to take an interest in hobbies or games. The three ways of dealing with the problem were: (1) distribution of the strain by reducing work periods and providing a midday pause of half an hour when the child could do exactly what it liked; (2) free time—rightly used (at Felsted the hobbies and clubs were housed in a big country house, with a warden to help boys out of difficulties, where each could follow his bent); (3) morning and evening chapel which provided ten minutes of detachment at each end of the day.—Dr. Alice Sanderson Clow (Cheltenham), who followed, held that children needed protection against their own energies rather than stimulation. Great responsibility rested on the parent and head of a boarding-house in detecting the early signs of fatigue. By the time the doctor was consulted the symptoms were anxiety, diminished concentration, stooping, loss of appetite, and broken sleep, and the only remedy was prolonged absence from school. A brain once impaired by prolonged fatigue rarely, if ever, recovered completely. The greatest feature in modern strain seemed to be the external examination taken too young. The morning session should be from 9 to 12.40, with 5-minute intervals of complete relaxation between the 40-minute lessons and a 30-minute break in the middle of the morning. Children found essay writing a great strain, and the homework set was usually too long for all but the brightest. Some homework was good in that it could be done in the evening, allowing the child to get out in the afternoon sun. A tired child sought rest rather than play, and might be overdone by organised games, especially with the element of competition. A little girl of 12 who had recently gone to her first boarding-school had said, "Oh, everything is lovely—but there's no time to play." "But don't you have games?" "Oh, yes, we have lots of games and they're glorious. But they're not play." Dr. Clow contrasted the white limbs of school-children on the beach early in the holidays with the bronze of their parents and baby brothers; school-children were often kept in high collars, in order to display the school tie, and in gloves and long black stockings which were unhygienic from every point of view.—Mr. A. J. R. Roberts (head of Mill Hill junior school) had known in many years' experience only one breakdown, which had taken place during holiday time. The régime of his school included most of the desiderata mentioned. Boys who spent themselves in nervous energy must be given a day in bed now and then.—Mr. Lee-Browne (head master of Rendcomb College) also outlined his time-table; teaching periods had been reduced to 28 and preparation to 7½ hours for boys up to 15 and 10½ hours over that age. These hours included music, drawing, and manual work; and there had been no falling off in scholastic success as a result. His boys got about 20 hours of spare time a week, with 8 on Sunday, on which day 1 hour must be spent in compulsory quiet. Value had been obtained from a brief exercise before breakfast followed by a cold bath. Recently they had instituted, with great success, one completely free afternoon a week when boys could do exactly what they liked—work or play. There was a very real problem of holiday pressure—the pressure of the car-

the cinema, or even the organised camp. The time for character training had been squeezed almost out by new subjects in the curriculum. If the number of teaching hours could not be reduced the period of school life would have to be lengthened.—Dr. Jessie White thought strain would be greatly lessened if children were allowed to move about freely while being taught, instead of being obliged to sit for long periods in cramped positions.

THE SELECTION OF AN ANÆSTHETIC

"Who pays the piper . . ."

BUT the patient would generally be very ill served if he were allowed to call the tune. The wise doctor will not categorically refuse his right to call it, but while appearing to concede the request he will do what he knows to be best for his patient. A few days ago a hospital visitor handed on to the executive committee a complaint by patients who had been given a local anæsthetic as a preparation for a major operation. Some persons, she said, had come to hospital expecting to have a general anæsthetic and had been shocked to find themselves conscious on the operating table. It may safely be assumed that the local anæsthetic was preferred for some good reason. There are occasions when, in some form or another, it is so much the safer method to adopt that the surgeon has no choice in the matter. There are others when the advantage is less decisive and when the patient may reasonably be given his choice. Perhaps when the inquiry suggested at the Manchester Medical Society (see p. 89) has been made there may be less room for such choice. But to put the pros and cons before the patient would generally be to ask him to answer a question the full bearings of which he cannot possibly realise. When as a result of previous experiences of his own he holds definite views as to the anæsthetic which suits him the anæsthetist will weigh these before he makes up his own mind. What anæsthetist has not met the patient who "cannot take ether; they tried to give it to me but it's no good"? And what anæsthetist has not in those circumstances started the administration with something else and then gone on to give ether without a hitch? The same thing is true of almost any anæsthetic. But every anæsthetist knows the importance of a quiet mind in the subject for operation; it is half the battle that the patient should believe from the start that what is being done is suitable to him and in accordance with his desire—if he has expressed one.

THE KEEP FIT ADVENTURE IN SUNDERLAND

THE development of the Keep Fit movement in Sunderland ought to dispel any doubts whether youths and men and girls and women of this country are ready to respond to opportunities of organised physical training when they are offered by an organiser of inspiring zeal. Chapter II. of the report of the C.M.O. of the Board of Education, to which reference has already been made, relates the history of the movement. To the very first class, held in the winter of 1929, there came 127 girls, and on the evening of May 8th, 1935, no fewer than 1450 women and girls took the field in a mass demonstration. A ten-fold increase in six years clearly proves the case for such an "adventure." Throughout the 25 weeks of that first winter season, two classes were held, one for girls under 16 years of age and one for older women. The organiser took both these classes herself, but as the numbers increased it was found necessary to appeal for voluntary leaders to take extra classes. In response to this appeal, 17 elementary school teachers and three trained gymnasts came forward to offer their help.

From 1930 onwards demonstrations have been given in various parts of the counties of Northumberland and Durham, and it has been found that this is

one of the most effective means of spreading the work and of arousing enthusiasm. Through the coöperation of the chief education officer and of headmasters and mistresses of schools with good halls, arrangements were made whereby halls became available to the movement at the cost of paying each caretaker the fee of 1s. per class. In 1930 there were nine classes running in different parts of the town, with an average attendance of 500 a week, but by the end of 1934 there were 18 classes, with an average attendance of 1000. At the beginning all classes were for anybody and everybody, but soon there sprang into being one special class for mothers only, provided with a nursery, and two classes for women over 40. The leaders are now sufficiently trained to give courses of lessons.

As far back as 1931 Sunderland leaders of classes were taking classes outside the Sunderland area. Then organisers in Northumberland and in Newcastle began to train leaders, and so the work spread to various districts, each district supporting itself. Sunderland is very proud of its "keep fit" adventure, and the officers of the local education authority have had the reward of seeing those for whom they have worked reaping the full benefit of their efforts. The movement is spreading to Huddersfield, Halifax, and other northern towns.

THE "REALITY" OF PAIN AND DISEASE

Mr. CHARLES W. J. TENNANT, district manager of the Christian Science Committees on Publication for Great Britain and Ireland, writes: In his lecture on Medicine and Faith published in your issue of Dec. 28th, 1935, Dr. Louis Leopoldt, quoting from the fifth chapter of the Epistle of St. James, infers that pain and disease must be regarded as realities, "and not, as the Christian Scientists would have us believe, as mere figments in a perfect world." To a Christian Scientist "reality" means that which is "spiritual, harmonious, immutable, immortal, divine, eternal" ("Science and Health with Key to the Scriptures," by Mary Baker Eddy, p. 335). If disease were a reality in the above sense, it could never be cured. God is the creator of all that is real, eternal, immutable, and immortal. Therefore sin, disease, and death, which do not proceed from God, are unreal, and can only be the erroneous conceptions of a false material sense. Christian Scientists, in the measure of their spiritual understanding, are daily proving the unreality of evil by healing the sick and reforming the sinner through spiritual means alone in fulfilment of our Master's command.

NEW PREPARATIONS

"KALDROX" ABSORBENT COMPOUND is described as a palatable emulsoid of colloidal kaolin and aluminium hydroxide gel, the formula being kaolin 20, aluminium hydroxide 2.5, aromatics 0.008, aqua destill. to 100. It is used to remove excess acid from the stomach by adsorption and provide a protective covering for irritated mucous membrane, thus relieving the pain or discomfort often associated with peptic ulceration; it is also recommended for diarrhoea and conditions designated "colitis" or "unstable bowel." The makers are Petrolagar Laboratories Ltd., Braydon-road, London, N.16.

BELLERGAL.—Each tablet contains 0.001 g. of Bellafoline (laevorotatory alkaloids of belladonna), 0.0003 g. of Femergin (ergotamine tartrate), and 0.02 g. of phenobarbital. It is designed to overcome excessive autonomic nervous tone; the belladonna restrains over-activity of the sympathetic, while the ergotamine inhibits the parasympathetic—the two forms of hypertonus being often associated though one of them may predominate. Experiments are held to show that the individual actions of belladonna and ergotamine are not impaired by mixing them in Bellerгал and that the central sedative action of phenobarbital is increased. The remedy is prepared by Sandoz Products (134, Wigmore-street, London, W. 1), and is recommended especially for the prevention of migraine and asthma, and the treatment of

Graves's disease, urticaria, pruritus, night-sweats, and functional nervous disorders. The dose proposed is 3-4 tablets daily, or sometimes more.

"TABLOID" BLAUD PILL AND COPPER.—It has been suggested that the therapeutic action of iron is enhanced by the addition of minute quantities of copper. Quoting work by M. S. Rose (1932), Prof. L. J. Witts stated in our last issue that "in experimental animals iron can be absorbed and stored in the liver but cannot be converted into hæmoglobin unless copper is also present." How far a physiological deficiency of copper can occur in the human beings is open to question, but the use of this metal in conjunction with iron may perhaps be effective in some cases where iron alone has failed. For the convenience of those physicians who favour its administration Messrs. Burroughs Wellcome and Co. (Snow-hill Buildings, London, E.C. 1) are now issuing Bland Pill (pil. ferri carb. B.P.) and Copper in the form of Tabloids. Each contains 10 grains of the pill and 1/100 grain of copper sulphate.

APONDON "DIWAG" is a preparation of thyroid recommended for use in obesity. The objection to using thyroid by itself is that it gives rise to symptoms such as tachycardia and restlessness, and in Apondon this obstacle is overcome, it is claimed, by the addition of a sympathetic depressant, Ergocholin "Diwag," made by the same firm, Dr. Joachim Wiernik A.-G., Berlin-Waidmannslust. Each pill includes 5.25 mg. of the Ergocholin and 114 mg. of standardised thyroid gland (= 0.5 mg. iodine) and the suggested dose is 1-2 pills daily at first and 2-4 later. The preparation is distributed in this country by Messrs. Coates and Cooper Ltd. (94, Clerkenwell-road, London, E.C. 1).

We have received from the MARMITE Food Extract Company a booklet which sets out clearly under three main headings evidence of the potency of the product in the vitamin-B complex, of its efficacy in the treatment of certain anæmias, and of its value in tropical medicine. Some 70 recent references to medical literature are quoted in support of the claims made, and a dosage table and details as to administration are appended.

Births, Marriages, and Deaths

BIRTHS

- ANDERSON.—On Jan. 3rd, to Margaret (née Hutton), wife of Dr. E. W. Anderson, a son.
 BULL.—On Jan. 1st, at Devonshire-place, the wife of Dr. Cecil Bull, of a daughter.
 DICKS.—On Jan. 6th, at Blackheath, the wife of Henry V. Dicks, M.D. Camb., of a son.
 MACLAY.—On Jan. 4th, at Kensington-square, W., the wife of the Hon. W. S. Maclay, M.D. Camb., of a daughter.

MARRIAGES

- OWEN—CHIOZZA MONEY.—On Dec. 31st, 1935, at Caxton Hall, Thomas Owens, M.R.C.S. Eng. (Camb. and St. Bart.'s), to Gwendolen Doris, only child of Sir Leo and Lady Chiozza Money, of Bramley, Surrey.
 REWCASTLE-WOODS—LESTER.—On Nov. 30th, 1935, at Hong-kong, Dr. T. G. Rewcastle-Woods to Bertha Iris Lester. (Address, Methodist Mission, Hankow, Hupeh, China.)

DEATHS

- BROWN.—On Jan. 3rd, at Bedford-square, W.C., Haydn Brown, L.R.C.S. Edin.
 COULDBREY.—On Jan. 5th, at Scunthorpe, Lincs, Thomas Reginald Couldrey, M.R.C.S. Eng.
 GIBSON.—On Dec. 27th, 1935, at Paradis, Grange, Guernsey, Edmund Valentine Gibson, M.D.
 GRAY.—On Jan. 4th, at Glasgow, Albert Alexander Gray, M.D. Glasg.
 MORRIS.—On Dec. 31st, 1935, at Caerleon, Monmouthshire, Lieut.-Col. William Albert Morris, L.R.C.P. Edin., R.A.M.C. (retd.), in his 79th year.
 ORLEBAR.—On Jan. 2nd, at Hove, of acute pneumonia, Jeffery Alexander Amherst Orlebar, M.B. Camb.
 READ.—On Jan. 2nd, Mabyn Read, M.D. Camb., D.P.H., Medical Officer of Health for Worcester, 1891 to 1929, aged 81.
 WHITE.—On Jan. 5th, at St. Bartholomew's Hospital, Rochester, Clement John Goodhugh White, M.B. Camb., aged 27 years.
 N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

DIABETES MELLITUS

ITS DIFFERENTIATION INTO INSULIN-SENSITIVE AND INSULIN-INSENSITIVE TYPES*

By H. P. HIMSWORTH, M.D., M.R.C.P. Lond.

DEPUTY DIRECTOR OF THE MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON

In previous publications¹⁻⁵ it has been shown that the efficiency with which insulin acts in the body is governed by an unknown factor or condition which renders the body sensitive both to injected and pancreatic insulin. When this sensitising factor is limited the efficiency with which each unit of insulin depresses the blood-sugar is decreased, and when it is abundant the efficiency of each unit is correspondingly increased. It can easily be seen that if this sensitising factor is limited below a certain degree, then the insulin in the body will be relatively powerless and the symptoms and signs of hypo-insulinism, clinically recognisable as diabetes mellitus, will appear. This consideration led me to suggest^{4, 5} that a type of diabetes mellitus might exist which was due, not to lack of insulin, but rather to lack of this sensitising factor. An investigation of cases of diabetic patients from this point of view was therefore commenced.

At first sight the simplest method of testing this hypothesis would appear to be by comparing in different diabetic subjects the rate and extent of fall of the blood-sugar after a standard dose of insulin. Such comparison of insulin depression curves from diabetic patients is, however, impossible. Insulin depression curves are only comparable when obtained from one and the same subject and, even then, only if the initial blood-sugar values of the different curves are within a few mg. per 100 c.cm. of the same level.³ A new test was therefore sought and found in the application of an observation previously made on animals.³ If glucose and insulin are given simultaneously to a normal animal, then the extent to which the injected insulin suppresses the hyperglycæmia, consequent upon the administration of glucose, is determined by the sensitivity of the animal to insulin. This test has two great advantages over the insulin depression curve. Greater changes of the blood-sugar occur, and therefore minor variations consequent upon differences of the fasting blood-sugar level of the order of 50 mg. per 100 c.cm., may be disregarded; the effect of insulin in suppressing hyperglycæmia can be gauged by comparing the blood-sugar curve resulting from glucose alone with the curve resulting from glucose plus insulin.

THE TEST

The patient receives no food or insulin after supper the previous evening and the test is carried out next morning. Blood-sugar estimations are performed on capillary blood. Three resting samples are taken. The patient is given the appropriate dose of insulin intravenously and immediately afterwards the appropriate dose of glucose to drink. A blood sample is taken 5 minutes after the insulin injection, the next at 10 minutes, and subsequent samples at intervals of 10 minutes until the hour is reached, and then two more samples at 15 minute intervals. The test is thus completed in 90 minutes.

* Part of this work was done during the tenure of a Beit memorial research fellowship.

The doses of insulin and of glucose can conveniently be based on the surface area of the patient. The patient's height and weight being known this is determined from the appropriate nomogram.⁶ In our tests 30 grammes of glucose and 5 units of insulin per square metre of body surface were allowed. The glucose was given dissolved in half a pint of cold water and flavoured with citric acid and essence of lemon; the insulin used, for which I am indebted to Dr. J. W. Trevan of the Wellcome Physiological Research Laboratories, was a sterile solution of crystalline insulin assayed at 10 units per c.cm.

Various precautions are necessary to obtain satisfactory results. Firstly, the test must not be carried out if the patient shows signs of nausea or faintness. In these cases absorption from the stomach is delayed and a fallacious result obtained. Secondly, if it is desired to compare a series of curves, the patients must all be receiving diets containing approximately the same amount of carbohydrate, as I have previously shown that the insulin sensitivity of a normal subject is determined by the amount of carbohydrate utilised.⁵ In the case of diabetics care should be taken that sugar is not being excreted in the urine in such amounts as to reduce materially the carbohydrate supply of the body. Thirdly, conditions of exercise will very probably affect the test. This factor did not apply in my cases, as all the subjects were hospital in-patients and advantage was taken of this fact to perform the test under "basal conditions."

RESULTS

The work had not proceeded far before it became clear that by means of this test diabetics can be differentiated into two types: those in whom the injected insulin produces an immediate suppression of the hyperglycæmia which normally follows ingestion of glucose alone; and those in whom the insulin has little or no effect in suppressing this hyperglycæmia. In Fig. 1 a typical curve from each type of patient is shown. In patient I. the insulin has had little effect, whilst in patient II. not only has the hyperglycæmia been suppressed but an actual depression of the blood-sugar level has been produced. Patient I. is insulin-insensitive; patient II. is insulin-sensitive. Point is lent to these results when it is noted that patient I. passed only small amounts of sugar when receiving 20 units of insulin a day, whilst patient II. required 95 units of insulin a day to keep her sugar-free. Reference to the curves marked "capillary blood" in Fig. 2 show that in patient III., who is insulin-insensitive, there is very little difference between the curve after glucose alone (III. A) and the curve after giving the same dose of glucose and in addition insulin (III. B), whilst the capillary blood curves for the insulin-sensitive patient IV. differ widely when in one case only glucose is administered (IV. A), and in the second glucose and insulin (IV. B).

It may here be noted that the curve in healthy subjects approximates to that of the insulin-sensitive diabetics.² The curve obtained in this type of patient (II. and IV.) thus appears capable of easy explanation as being the result of normal insulin action.

The curve in the insulin-insensitive patients (I. and III.) is more difficult to explain. Three distinct possibilities offer themselves: (i) the liver may be pouring so much sugar into the blood that the effect of the injected insulin is swamped; (ii) the liver may be incapable of storing the ingested sugar; (iii) the characteristic action of insulin in promoting

storage of blood-sugar in the peripheral tissues may be unable to manifest itself. The first two possibilities involve the portal system, the third the peripheral tissues. If now it is possible to compare the removal of sugar by the peripheral tissues, firstly, when glucose is given alone, and secondly, when glucose is given along with insulin, the site of the functional derangement can be localised either to the periphery or to the portal system. This can be done by measuring the sugar content of the blood entering a limb and the sugar content of the blood leaving the limb.

I have shown that capillary blood taken from the warm ear has approximately the same sugar content as arterial blood, and also that venous blood specimens taken under identical conditions from the same half inch of vein in all tests on the same subject give a reliable if only relative indication of the sugar content of the blood leaving the limb.² By performing simultaneous curves on capillary and venous blood (A.V. curves) after ingestion of glucose and after glucose and insulin, and comparing the size of the capillary venous blood difference (A.V. difference), a rough estimation can be made of the extent to which insulin promotes peripheral storage in a particular case. In the normal subject the giving of insulin along with glucose results in a tremendous increase in the A.V. difference as compared with the increase of A.V. difference after glucose alone.² This increase is so great as to be quite outside the limits

of experimental error. A.V. curves were, therefore, performed on both insulin-sensitive and insulin-insensitive diabetics. The results are shown in Fig. 2.

In the insulin-sensitive patient IV. insulin had the normal effect of greatly augmenting the A.V. difference after glucose. Up to 60 minutes the area enclosed between the capillary and venous blood-sugar curves of curve IV.B, as compared with curve IV.A, increased by 120 per cent.

In the insulin-insensitive patient the effect is quite different. On comparing curve III.A (glucose alone) with curve III.B (glucose

+ insulin), it will be seen that the insulin has resulted in little or no increase of A.V. difference. By actual measurement of the areas enclosed between the capillary and venous blood-sugar curves the increase is found to be the negligible figure of 9 per cent.

It may thus be seen that, in the insulin-insensitive diabetic, insulin is unable to exert its characteristic action of effecting the transference of sugar from the blood to the peripheral tissues; that even if the insulin-insensitive patient possessed a normal supply of pancreatic insulin such insulin would be unable to act efficiently and the patient would be diabetic. On the other hand, it is seen that in the insulin-sensitive diabetic insulin is able to act, that the giving of this substance produces a normal reaction, and that, therefore, if these diabetics had a greater supply of pancreatic insulin, they would show no signs of diabetes mellitus.

It therefore appears that in insulin-sensitive diabetics the disease is due to deficiency of insulin, whilst in insulin-insensitive patients diabetes mellitus results, not from lack of insulin, but from lack of an unknown factor which renders the body sensitive to insulin.

CLINICAL OBSERVATIONS

Sufficient data have not yet been accumulated to permit a precise correlation between the clinical findings and the type of diabetes mellitus as revealed by the glucose-insulin test. But enough observations have been made to allow certain tentative opinions to be expressed.

A general relationship appears to exist between the type of onset of the disease and the type of diabetes. The onset in insulin-sensitive patients is as a rule acute; the onset in insulin-insensitive patients is insidious. For example, in the insulin-sensitive patient II. (a girl aged 21), the diabetes mellitus appeared with intense symptoms, and within 48 hours the patient was in coma; in the insulin-sensitive patient IV., a man aged 48, the disease came on suddenly in December, 1930; in the insulin-insensitive patient I., a woman aged 60, the patient developed vulvitis without symptoms of thirst or polyuria, the urine was tested and sugar was found; and in the insulin-insensitive patient III., a man aged 60, sugar was discovered fortuitously at a life insurance examination seven years ago, but none of the classical symptoms of diabetes mellitus have ever been noted and no therapeutic measures were taken until he developed first an external rectus and later a facial nerve palsy. The insulin-insensitive type is more common in but not confined to the elderly, whilst the insulin-sensitive type is commoner in the young. As diabetes mellitus becomes more frequent with increasing age it would appear probable—and my experience so far supports this deduction—that the commonest type of diabetes mellitus will eventually prove to be that which is not essentially due to insulin deficiency.

A further observation concerns the different reaction of the two types to change in the carbohydrate content of the diet. When high carbohydrate diets were first introduced the claim was made that the carbohydrate content of the diabetic's diet could be raised from the 50 g., then orthodox, to 200 g., without necessitating any increase in insulin dosage.⁷⁻⁹ It has been my experience that in many cases this claim is true, but it has been denied by other observers. The differentiation of diabetics into insulin-sensitive and insulin-insensitive types seems to provide the key to the discrepancy. In the cases examined so far it appears that insulin-sensitive diabetics will tolerate large increases of carbohydrate in the diet with little

FIG. 1.—Simultaneous glucose and insulin test. Capillary blood-sugar curves.

Patient I.—Insulin-insensitive. Woman, aged 60, on a diet of 1500 calories containing carbohydrate 150 g., protein 80 g., fat 66 g., and 35 units of insulin daily. Passing small amounts of sugar.

Received 7.3 units of insulin intravenously and 43.8 g. of glucose orally. Fasting blood-sugar 208 mg./100 c.cm.

Patient II.—Insulin-sensitive. Woman, aged 21, on a diet of 2000 calories containing carbohydrate 208 g., protein 80 g., fat 94 g., and 95 units of insulin daily. Sugar-free. No hypoglycaemic attacks.

Received 7 units of insulin intravenously and 41 g. of glucose orally. Fasting blood-sugar 244 mg./100 c.cm. The curves have been charted so as to start at the same resting blood-sugar level.

or no increase in the amount of insulin required to keep the urine sugar-free; insulin-insensitive patients, on the other hand, pass sugar after only small increases in dietetic carbohydrate. For example, patient I. was always sugar-free when taking a diet containing 67 g. of carbohydrate and 20 units of insulin a day. Increase of the carbohydrate to 148 g., whilst keeping the calorie value of the diet the same, resulted in profuse glycosuria which was not controlled by 35 units of insulin a day. On admission, patient II., who was insulin-sensitive, was receiving a diet containing 65 g. of carbohydrate and was taking 45 units of insulin a day. Her physician had been quite unable to balance her, she was extremely wasted, and her urine contained sugar and ketones in large quantities. She was given a diet containing 200 g. of carbohydrate a day and rendered sugar-free with 95 units of insulin daily. After ten days of complete control, in which no hypoglycæmic attacks occurred, she was given an equicaloric diet containing 320 g. of carbohydrate. Glycosuria did not appear and some days later the insulin dose had to be reduced because of hypoglycæmic attacks.

It thus appears that the differentiation of diabetics into insulin-sensitive and insulin-insensitive types by means of the insulin-glucose test may prove to be of considerable practical importance as offering a means by which the appropriate diet can be chosen for the particular case. It is hoped that other observers will attempt to arrive at an opinion on this point. One thing, however, I would make clear. The observation that on a low carbohydrate diet a particular diabetic requires least insulin is no proof that the diet is the optimum from the point of view of the preservation of his health.

DISCUSSION

I have said that I think it probable that in those cases of diabetes mellitus which are insulin-sensitive the cause of the disease is deficiency of insulin, whilst in those cases which are insulin-insensitive the cause of the disease is not lack of insulin, but the restriction, to a greater or less degree, of an unknown sensitising factor. In previous publications I have communicated the results of work on healthy men and animals which demonstrated the existence of a factor rendering the body sensitive to insulin.^{4,5} It is of interest to inquire whether it is the restriction of this same factor demonstrable in healthy subjects which is responsible for the insulin insensitivity of a type of diabetes.

A characteristic of the insulin-sensitising factor of normal people is that the quantity of it present in the tissues at any time is determined by the amount of carbohydrate in the diet.⁵ When more carbohydrate is given to a healthy subject the body reacts by rendering itself more sensitive to insulin. Now it has been shown in the previous section that when more carbohydrate is given to an insulin-sensitive diabetic the insulin requirement does not increase and glycosuria does not appear. I have shown elsewhere⁴ that this apparent increase in efficiency of the injected insulin can satisfactorily be explained on the basis that these patients react to the increased amount of dietary carbohydrate by becoming more sensitive to the injected insulin. But in the case of the insulin-insensitive diabetic increased intake of carbohydrate results in glycosuria and consequent increased insulin requirement. Thus, these patients are abnormal in being unable to react to increase in dietary carbohydrate by increase in their sensitivity to insulin. It appears, therefore, justifiable to regard the insulin-insensitive type of diabetes as being due

FIG. 2.—Simultaneous glucose and insulin test. Simultaneous capillary and venous blood-sugar curves (A.V. curves).

Patient III.—Insulin-insensitive. Man, aged 61.

Curve IIIa.—53 g. of glucose by mouth. Resting capillary blood-sugar 149 mg./100 c.cm., venous blood-sugar 147 mg.

Curve IIIb.—53 g. of glucose by mouth immediately preceded by 8.8 units of insulin intravenously. Resting capillary blood-sugar 141 mg., venous blood-sugar 139 mg.

Receiving a diet of 1570 calories containing carbohydrate 210 g., protein 70 g., fat 60 g. for the previous ten months. Insulin dosage raised steadily until, on admission to hospital, was receiving 85 units of insulin. This was inadequate. Every specimen of urine passed gave a complete reduction of Benedict's solution, and no hypoglycæmic attacks occurred.

Patient IV.—Insulin-sensitive. Man aged 48.

Curve IVa.—50 g. of glucose by mouth. Resting capillary blood-sugar 152 mg., venous blood-sugar 147 mg.

Curve IVb.—50 g. of glucose by mouth and 5 units of insulin intravenously. Resting capillary blood-sugar 171 mg., venous blood-sugar 169 mg.

Receiving a diet of 2493 calories containing carbohydrate 238 g., protein 102 g., fat 115 g., and 20 units of insulin a day. Consistently sugar-free.

* These doses of insulin and glucose were chosen before the scheme of dosage based on surface area was adopted. The dose on surface area would have been 58 g. of glucose and 9.7 units of insulin.

to lack of that same unknown factor which in the normal subject produces sensitivity to insulin.

On the balance of the evidence available I have suggested that this insulin-sensitising factor is an activator of insulin,^{1,2} but as yet there is no incontrovertible evidence whether the unknown is a factor, in the sense of being a definite substance, or a condition of the tissues in general which facilitates the action of insulin. It will be seen, however, that the nature of the unknown "insulin-sensitising factor" must be such that it is intimately concerned with the action of insulin and that its restriction will result in rendering a proportionate amount of the available insulin powerless.

The term insulin insensitivity has been used in preference to the term insulin resistance for two

reasons. Firstly, because in my investigations into the variations of insulin sensitivity in normal subjects I have seen no evidence of any factor which antagonises or resists the action of insulin itself, but only evidence indicating the presence of a factor which is complementary to insulin. Secondly, because the term insulin resistance has already been used with two different meanings.¹⁰ In one sense it appears to mean simply that the patient requires more insulin to produce hypoglycæmic symptoms than the physician expected. In the other sense it refers to those rare cases in which enormous doses of insulin, such as 1600 units a day, are insufficient to prevent the patient developing and dying in diabetic coma.^{11 12} These latter cases cannot be explained on the basis of lack of insulin, but I would suggest that they can be explained on the basis of extreme deficiency of the insulin-sensitising factor.

SUMMARY

It is shown that two different types of disease can be distinguished as causing the symptom-complex of diabetes mellitus. One, the insulin-sensitive type, appears to be caused by deficiency of insulin; the other, the insulin-insensitive type, is apparently due not to lack of insulin, but to lack of an unknown factor which sensitises the body to insulin. A test for distinguishing these two types of diabetes mellitus is described. The appropriate dietetic treatment of the two diseases may differ.

ADDENDUM

Since this paper was written I have read a publication by Boller and Uiberrack in the *Falta-festschrift* (Wien. Arch. f. inn. Med., 1935, xxvii., 75) which bears on these results. These workers chose diabetics of two types: those who required less insulin than was estimated to produce hypoglycæmic attacks, the "insulin-sensitive" group, and those who required more insulin than was expected, the "insulin-resistant" group. Amongst the different experiments performed one series is relevant to this paper. Insulin was injected and some hours later when hypoglycæmic symptoms appeared glucose was given by mouth. In the "insulin-sensitive" group the oral glucose resulted in a smaller hyperglycæmia than in the "insulin-resistant" group. The authors explain their results by the varying sensitivity, in the two types of case, of the mechanism which causes liberation of sugar into the blood stream. As my results show, this cannot be the explanation; for the difference is due not to swamping of insulin action by pouring of sugar into the blood, but to deficient removal of blood-sugar due to inefficient insulin action. Their results, however, are of importance as showing that the type I have called insulin-sensitive easily develops hypoglycæmic symptoms, whilst the type named insulin-insensitive develops these symptoms with difficulty.

CARCINOMA OF THE ŒSOPHAGUS THE QUESTION OF ITS TREATMENT BY SURGERY

BY G. GREY TURNER, M.S., F.R.C.S.

(Bradshaw Lecture concluded from p. 72)

Œsophagectomy

It may be taken as an axiom that it is not practical to excise a sufficient length of the œsophagus for cancer and to make a union in situ, for the ends cannot be opposed without tension if more than 4 cm. is removed. This amount would not be sufficient for the eradication of any malignant neoplasm likely to be met with. A study of cancer of the œsophagus and its mode of spread shows that we must excise not only a sufficiency of healthy tube on either side of the growth, but as much extra œsophageal tissue as possible. Most growths are from 1 to 3 in. in length and because of the tendency to spread up and down under the mucosa, at least 1½ in. and better 2 in. should be removed beyond the margin of the growth on either side. In other words, it is essential to remove a large section of the œsophagus if the ablation is to hold out any prospect of eradicating the disease. Many growths are of such longitudinal length that nothing short of removal of the whole œsophagus can hold out any chance of success and any more limited excision is bound to be attended by recurrence. If these requirements are admitted, then it can only be in a few cases of carcinoma of the lower end that a direct anastomosis can be made between the mobilised stomach or the small bowel by the abdominal or abdomino-pleural route. Even if it is justifiable to contemplate this plan, it must be realised that the actual junction will have to be made to that part of the œsophagus where its blood-supply is the most precarious. In most cases when this has been attempted there has been leakage at the suture line.

Some of the operations for excision of the œsophagus which have been recommended and which are freely illustrated in books must be looked upon as largely armchair exploits and doomed to failure in practice. This especially applies to those methods which must rely for their success on the isolation of a considerable area of the œsophagus, which is thus denuded of its blood-supply at the part which is to be anastomosed to the stomach. Similarly those procedures which depend for their success on the displacement of a large part of the stomach into the chest have not been successful, largely because of the failure of the blood-supply of the displaced viscus. After all, the one essential is to remove the growth as completely and widely as possible and without reference to the repair of the œsophagus. If the patient can be safely piloted over this ordeal, the restoration of the power of swallowing need not present an insuperable problem.

There can be no doubt that in many cases in the past the real difficulty has been that associated with the exposure of such a deep-seated organ. In recent times however, since the practical methods of approach have been better understood, I think one may say that what has defeated our efforts on most occasions has been the comparatively advanced stage at which the patients reach us. As a rule it is possible to determine the presence of distant dissemination, but our methods of assessing the local extension of many of the growths have not been sufficiently helpful and definite to enable us

to say at what stage local fixation by extension of the growth has gone too far for possible removal.

Another great difficulty has been the question of infection of the cellular tissue. In my own cases some of the deaths have been due to technical errors which could be avoided. When I first contemplated the possibility of removing growths by the "pull-through" method, my principal concern was the question of hæmorrhage, and that still remains a main consideration. Though it may not be serious as borne out by several cases, including the one completely successful issue, one must admit that in those that have died this factor has sometimes played a considerable part.

CHOICE OF METHOD

As the result of the considerations which I have put before you I have formulated certain definite though admittedly tentative conclusions for my own guidance. If in a case of known cancer of this tube there is no evidence to show that there is already dissemination and nothing to suggest that local fixation is well marked, then I would undertake operative measures for its removal.

There are many successful cases on record of excision of malignant growths of the cervical œsophagus with restoration by plastic reconstruction with skin flaps. Most of these have really been growths of the lowest part of the pharynx and commencement of the œsophagus. The results have sometimes been very wonderful and encouraging, and the methods employed are now established surgical procedures. But I have only in mind growths which are strictly in the œsophagus at the root of the neck. In such cases the growth usually extends below the level of the manubrium in such a way that it is not possible to remove it with a sufficient margin of healthy tissue on either side and at the same time to make a plastic restoration. The problem is therefore the same as in connexion with the growths in the posterior mediastinum. When the growth is in the upper 2 or 3 inches the approach should be from the neck in the first instance. If it can be separated all round with the finger, then I should be prepared to pursue this as far down as it could be conveniently reached from the neck. If it were possible to ligature or to clamp the œsophagus well below the growth, then I should cut it across and bring the upper end out on to the chest wall as I have already described. If divided by the cautery or divided and thoroughly carbolised and bipped, the lower end of the œsophagus may be relied upon to look after itself and probably the upper part of its bed would become safely obliterated.

If the growth is situated in the lower 2 or 3 inches, then the approach should be from the abdomen. If the growth could be separated all round and the lower part of the œsophagus mobilised, then I would suggest that the case is worth the complete "pull-through" operation, and I would endeavour to carry out extirpation by that means. If, on the other hand, the growth was situated in the middle of the thoracic œsophagus, then my present view would be in favour of either the "pull-through" method or a combined posterior mediastinal and transpleural exposure, completing the procedure as in the successful case operated upon by Torek. The lower part of the œsophagus divided not less than two inches below the growth is left behind.

In deciding the route to be employed in any contemplated excision the type and build of the patient must be taken into consideration. Those of short stature, even though the chest is voluminous, have shorter œsophageal tunnels than others, and condi-

tions are still more favourable if there is marked kyphosis. In such subjects it is possible to make the fingers meet in the tunnel when passed from the neck and the abdomen. For the same sort of reason those who are rather tall and slight present a much easier problem for the transpleural approach. The type of costal angle gives a very good indication of these anatomical differences.

SELECTION AND PREPARATION OF PATIENTS

It will be well in considering this matter to be guided more by the vigour, physique, and especially courage of the patients, than merely by terms of years. It is most important that these patients should have a great desire for food and an ardent wish to have the power of swallowing restored. Above all, I think it is important that they should have proved that they are suffering from a mechanical disability rather than absorption or cachexia, as shown by the fact of their great and striking improvement after gastrostomy or jejunostomy. I should just like to say that I believe the majority of patients with gastrostomy will recover better in their own homes. In hospitals the routine of feeding may be quite in keeping with physiological requirements, but it takes little note of those psychological factors concerned in digestion and nutrition. At their own homes the patients may find it easier to establish a régime which will satisfy both requirements, and as a result it is often found that they do better in these circumstances.

The question of the preliminary collapse of one or other lung is very important, but so far as this step is concerned I am prepared to occupy a position of suspense. In my completely successful case I contemplated collapsing the left lung, thinking that any injury to the pleura was most likely to occur on that side. As a matter of fact it was well that I did not do so, for it was the right pleura which happened to be opened at the operation. At the same time I certainly think that if it is proposed to adopt the transthoracic route, then it would probably be wise to have the corresponding lung collapsed as a preliminary. The mere opening of the pleura need not in itself be serious, and, in fact, I know from actual experience that both sacs may be opened without any positive pressure arrangements and the patient may easily survive the accident. But there is another reason why it is most important that the pleura should be preserved intact if possible, and that is so that hæmorrhage may be circumscribed by the intact œsophageal tunnel. I believe that when the pleura is opened it is much more likely that bleeding will continue after the œsophagus has been separated from its bed, and in several cases I have been struck by the amount of blood which may be found in the pleural sacs in these circumstances.

Operative Details

"There is a time and a way in which all things can be done; none shorter—none smoother. For all noble things, the time is long and the way rude . . ."—*John Ruskin*.

The story of the introduction of the "pull-through" or collo-abdominal method was related in my Bigelow lecture in 1931, and it is not necessary to repeat it here. Suffice it to say that the first "pull-through" operation was completed in December, 1927. Having been fortunate enough to carry the method to a successful issue in one case and to have come very near success in others, one feels that it may now be looked upon as a surgical procedure which is, at least, provocative of serious consideration. When

called upon to repeat that operation, I would incorporate the following modifications:—

- (a) A better approach from the neck to be obtained by the excision of the inner half of the clavicle.
- (b) Taking much more care to distend the cellular tissue by injection and to carry out the enucleation with especial gentleness and deliberation.
- (c) The completion of the removal by drawing the oesophagus up into the neck, rather than downwards into the abdomen.
- (d) Allowing the oesophagus, withdrawn from its bed, to lie free on the front of the chest until such time as the cellular tissue spaces of the neck and thorax are safely shut off.
- (e) Taking more active steps to combat hæmorrhage and delayed shock.

To gain access to the upper mediastinum the removal of the inner half of the clavicle is of great assistance. This step was suggested by a study of a preparation of the inlet of the thorax given me by Sir James Berry. I first employed the method in carrying out exploration of a growth of the upper part of the oesophagus, and it proved so helpful that I have continued to use it. Still further room may be obtained by cutting away the upper left corner of the manubrium sterni, but I have not usually found this to be necessary. The removal of so much of the clavicle does not appear to interfere materially with the usefulness of the arm. The idea underlying the second modification has been mentioned in the section on anatomy, and I feel sure it has been helpful. The withdrawal of the oesophagus upwards seems to have the advantage that it is but retracing the steps imposed upon it in the process of development, and, moreover, vessels and nerve-fibres are more likely to separate easily and tear, if pulled against the direction in which they normally grow. Further, this upward withdrawal greatly facilitates the next modification of importance, for it is desirable to have as long a portion of oesophagus as possible to bring out of the wound. The idea of allowing the oesophagus to lie well out of the wound until such time as the cellular tissue is shut off is thoroughly sound and practical; moreover it is in keeping with the known success of the two-stage method of dealing with pharyngeal diverticula. I first thought of and noted this plan in January of 1931 and yet, so treacherous is memory, that it was subsequently overlooked in two cases which I always believe would very probably have recovered had it been adopted.

The last modification is almost self-evident, but I venture to think it is of first moment. There is so great a risk of reactionary or recurrent hæmorrhage that every means possible should be taken to anticipate its onset, and for this purpose most careful hæmostasis at the time of operation and early hæmodynamic blood transfusion are essential. If it is not justifiable to regard the growth as early and probably free from fixation, it would be wiser to adopt Torek's approach so that the exact condition could be investigated under the guidance of the eye before any attempt was made at removal. By this plan even pleura adherent to the growth might be excised, and very careful and deliberate separation can be carried out and more care exercised in the control of bleeding. In these operations the hæmorrhage is mostly venous and can be controlled by very light pressure, and if the pleura is not opened there is much likelihood of it being spontaneously arrested. Should it be too free, as shown by its escape from the tunnel into the abdomen or the neck, it may be controlled by temporarily inserting a gauze strand, taking the

greatest of care not to damage the pleura during its introduction. Snake venom as a hæmostatic may also prove valuable; I have not as yet employed it. Another plan, which I have contemplated, is to introduce a rubber tampon made of the large size colotomy tubing. This could be drawn into the abdomen from the neck or vice versa, a stiff oesophagus tube being used as a pilot. The colotomy tubing would be introduced in the collapsed state and inflated with air or hot fluid when in situ. Having served its purpose, the tampon could be gradually deflated and withdrawn a little at a time in order to allow the empty tunnel to collapse.

Review of Lessons Learnt

It is very surprising how few of the patients have actually died as the immediate result of the operation. This has only been the case in one patient, an example of a posterior mediastinal removal in which the patient succumbed before leaving the theatre, but that was an advance case in which the growth was very adherent and had to be peeled off the aorta. As a rule the patients have left the operating table in wonderfully good condition, and in many of them the condition for several hours, that is to say until some other and secondary changes have taken place, has not given rise to anxiety. Some of the operations have really been of great magnitude, and one would have expected them to be attended or followed by great shock. In the patient who completely recovered the operation took 1 hour and 40 minutes, and was very well borne. In a recent case, a not robust old lady of 75, the operation lasted the same length of time. The oesophagus was exposed by the transthoracic route and the growth removed (Fig. 3), but both the neck and the abdomen had to be opened to remove either end.

In spite of so severe an ordeal the general condition was wonderful throughout, and she returned to the ward in what was considered to be good condition.

Any operation destined to remove an organ like the oesophagus is in itself a very major proceeding which must be a severe tax on elderly people whose nutrition has been seriously imperilled before the operation is undertaken. Most deaths have occurred within 12 to 24 hours, and the inclination is to put them down to delayed shock, but the autopsy usually furnishes another explanation. In four cases of collo-abdominal removal, in which a post-mortem examination was made, the pleura was torn on both sides in one and on the left in the others, with hæmorrhage into the pleural cavity in all. This bleeding was of

FIG. 3.—Well-developed carcinoma, with only four months' history, removed by transthoracic route.

variable quantity and was undoubtedly often exaggerated in amount by admixture with pleural exudation, but in each case I was satisfied that the amount was enough to contribute largely to, if not to explain, the fatal result. Bleeding has never been alarming at the time of the operation, but it probably slowly continues for some hours after the interference, so that the patients may be said to run the risk of bleeding to death into their own pleural cavities. In the cases in which a transpleural approach has been used there was also bleeding into the pleural cavities, despite the fact that in these patients the operation was conducted under the guidance of the eye and no obviously bleeding points were left unattended. One can only conclude that there is a risk of continued oozing, and that when the pleura remains intact it is restrained by the confines of the tunnel. Even when the pleura is not torn there is usually some retropleural hæmorrhage, but it has never been great in amount and I have never seen anything more than a localised hæmatoma. In no case has there been any considerable hæmorrhage into the peritoneal cavity, probably because of the close of the abdominal hiatus. This is brought about by stitching the left lobe of the liver over the aperture or packing the lower end of the tunnel with omentum.

In an endeavour to guard against injury to the pleura I have injected quantities of weak local anæsthetic into the cellular tissue surrounding the oesophagus with the idea that the bulk of fluid would push aside the serous membrane and would also open up the cellular spaces, thus making separation easier and facilitating the removal of the oesophagus, while reducing traumatism to the minimum. If it was known to have occurred, then the most important factor in reducing any evil results is probably the complete expansion of the lung.

In those cases that survived the first 24 hours, death was due to sepsis in some form. In no case was there an acute spreading mediastinitis, but in two there was a low form of infection. The three cases that lived 7 days, 8 weeks, and 9 days respectively were most instructive, for in each there was the most wonderful evidence of repair of the media-

stinal tunnel. The main features of the first two of these cases were described in a discussion at the Royal Society of Medicine in December, 1933.⁴ A more recent case operated upon at the Hammersmith Hospital was equally instructive and encouraging and for our purpose more useful, as I am able to show you the parts (Fig. 4).

FIG. 4.—The parts removed from a patient who died nine days after excision of the oesophagus by the "pull-through" method. The "tunnel" is beautifully demarcated, and there is no evidence of spreading inflammatory trouble. The inset shows the upper aperture from the front.

operation. An examination after death showed bilateral broncho-pneumonia with old healed fibrocaceous tubercle of the right lung. The bed from which the oesophagus had been removed was safely sealed at its lower end, and for the rest was beautifully shut off by organisation of its wall. The latter was smooth and regular and covered with small healthy granulations. It was an example of perfect preparation for healing and a wonderful exhibition of what nature can do. Although the cavity had been flooded with infected material for at least a week there was no evidence of any active infection whatever, and on microscopical examination very few organisms could be found.

The naked-eye appearances were confirmed by the microscope, and sections made from the upper end of the oesophageal tunnel showed a typical layer of granulation tissue with fibroblastic proliferation and an infiltration with macrophages, but very few polynuclears. One vessel in the deeper part showed endarteritis. Staining showed some Gram-negative cocci limited to the surface

The patient was a man, 60 years of age, who was admitted to hospital with only two months' history of difficulty in swallowing. Investigation disclosed an occluding growth opposite the fourth dorsal vertebra. It was removed by the collo-abdominal method without any special difficulty. By a most unhappy mischance which I shall always regret the oesophagus was cut too short in the neck. As a result its lower edge separated from the skin and retracted exposing the cellular tissue deep in the neck to infection from saliva, &c. All our efforts to control the ravages of this disaster were of no avail. The wound in the neck further separated and left the entrance to the mediastinum widely exposed. Saliva and discharge found their way into the oesophageal bed, and some ounces of infected fluid were sucked up from this pocket several times a day. As a result his condition deteriorated and the gastrostomy began to leak. This was repaired, but nutrition was too much undermined and death occurred on the ninth day following the

⁴ Proc. Roy. Soc. Med., 1934, xxvii., 355.

layer. At the lower end of the tunnel the section showed an essentially similar picture, only here the tissue was looser and the limits of the area of granulations less distinct. The surface also showed a thick layer of fibrin but no organisms were seen.

This risk of infection of the upper part of the œsophageal tunnel can probably be avoided by deferring the actual excision of the œsophagus until some days after its enucleation. The use of B.I.P.P. may also be of some little help; it is smeared over the end of the cut œsophagus before it is withdrawn and is rubbed into the walls of either end of the tunnel.

During the process of separation of the œsophagus and during its actual removal, great care must be taken not to tear it, and complete mobilisation must precede any traction. Instead of pulling on the extremity of the œsophagus, it should be grasped with sponge handles, the surgeon changing the hold of the forceps in order to get nearer and nearer to the site of any remaining attachment. When the time for the attempt at removal of the œsophagus arrives, the presence of the gastrostomy is often an embarrassment, and in two of the cases it undoubtedly contributed to the fatal result. In order to expose the diaphragmatic hiatus it is essential that the stomach should be free, so that it can be drawn down and to the right in order to put the abdominal part of the œsophagus on the stretch. In order to permit of the free handling of the stomach it has sometimes been necessary

to separate it from the parietes and to re-attach the gastrostomy opening as a last stage in the operation or to remake the gastrostomy.

Although I do not think that patients thrive as well on jejunostomy feeding as when fed directly into the stomach, still I am persuaded that jejunostomy would be an advantage in many ways. It was very satisfactory in the case in which I had to remove the whole stomach with the œsophagus and in another case of total gastrectomy. I am hoping that some day we will get these cases at so early a stage that neither preliminary gastrostomy nor jejunostomy will be necessary.

An Improvised Œsophagus

"Nothin's finished till it's done."—*Mrs. Jorrocks.*

As a commentary on the subject will you forgive me if I merely mention the case in which I was able to complete the excision by the "pull-through"

method and to restore the function of swallowing by the construction of a new œsophagus. A short account of this case has already been published.⁵ This man went along quite happily until eighteen months after the primary operation when he commenced to lose ground until he died a month later from nephritis. An examination of the body did not disclose any very obvious signs of recurrence of the growth. There was a small mass in the cardiac end of the stomach about two inches away from the situation of the normal œsophageal opening, and on section this showed histological characters of a type similar to the original growth. The new œsophagus shows a beautiful wide tube with an average diameter of one inch (Fig. 5). The wall of the new œsophagus is smooth, and there is no sign of irritation or suspicion of ulceration. The junction between the skin and the intestine is almost imperceptible and just as smooth and nice as in an old gastro-enterostomy. The interior of the dermal tube has a curious ringed appearance, rather suggestive of the inside of the trachea. There are a few long hairs growing into the lumen but certainly not in excess. Histological examination

reveals no striking changes in the skin in spite of its adaptation to a new function.

I am glad to have this opportunity of acknowledging the help of my colleagues of the British Postgraduate Medical School and the Hammersmith Hospital.

AN EMBRYOLOGICAL INTERPRETATION OF CHANGES INDUCED BY OESTROGENS IN THE MALE REPRODUCTIVE TRACT

By S. ZUCKERMAN, D.Sc. Lond., M.R.C.S. Eng.

BEIT MEMORIAL RESEARCH FELLOW

(From the Department of Human Anatomy, Oxford)

RECENT investigations on rats, mice, and monkeys indicate that changes induced by oestrone in the epithelium of the male reproductive tract may throw light on the aetiology of senile enlargement of the prostate in man. The morphological basis of the experimental response is thus a matter of the highest importance. Burrows,¹ following Lacassagne,² suggests that Müllerian epithelium enters into the formation of those organs (in particular the different lobes of the prostate) which in the male rodent respond to oestrone. This hypothesis, which immediately relates the effects of oestrone in the male to those produced by the hormone in the female (whose definitive reproductive tract is generally assumed to derive entirely from the Müllerian ducts) fails to account, however, for changes which oestrone occasions in parts of the male reproductive tract that undoubtedly are *not* related embryologically to the Müllerian ducts—e.g., in the rat, the entire urethra.¹ Unfortunately, too little is known of the development of rats and mice to allow even moderate certainty to embryological interpretations of the responses of the male to oestrone, while the homological relations of the rodent and human reproductive tracts are too speculative for comparative anatomical interpretations.

Facts derived from corresponding studies of monkeys are not subject to as many limitations, and they point to a more fruitful hypothesis, the gist of which is that oestrogens act specifically not only on Müllerian epithelium, but also on epithelium of the urogenital sinus. Many of the responses of the male become understandable in terms of this latter fact.

OBSERVATIONS ON MONKEYS

Apart from general fibromuscular growth in the stroma of both the prostate and the seminal vesicles, a response which can reasonably be regarded as an undifferentiated effect of oestrogens on tissues derived from the mesoderm of the genital cord, the conspicuous internal changes produced by oestrone in the reproductive tract of male monkeys are limited to the epithelium of the urethra and of the uterus masculinus (utriculus prostaticus). Of nine monkeys thus far tested,³ two (*Cebus fatuellus* and *Haplorhina jacchus*) showed no utricular response; one (*Presbytis entellus*) showed disorganised glandular hyperplasia of a utricle which normally comprises a regular system of tubular glands; and the remaining six, of which the best known is *Macaca mulatta*, the rhesus monkey, presented a utricular response essentially the same as that of the vagina to oestrone, the utricle becoming greatly distended and lined by a much stratified and desquamating epithelium. This type of utricular response is identical with the urethral response in those species in which the urethra is affected. In no case was the upper urethra responsive to oestrone; the sensitive region under the conditions of the present series of experiments extended from the region of the utricular opening to the urethral meatus. The upper insensitive section of the urethra arises with the bladder from the part of the ventral division of the entodermal cloaca lying above the opening of the Müllerian ducts, and it may include some epithelial remnants of the

Wolffian ducts, whose definitive openings are at the same level as the Müllerian.⁴

The uterus masculinus, like the vagina, is commonly believed to develop from the terminal part of the Müllerian ducts; histological difficulties, however, have obscured the picture of the actual embryological process. The view that unchanged Müllerian epithelium is responsible for the vaginal epithelium in man is not generally accepted. Alternative descriptions are that epithelium of the primitive urogenital sinus, into which the Müllerian ducts open, either partly,⁵ or entirely,⁶ replaces that of the Müllerian primordium of the vagina. It is reasonable to suppose that a corresponding process could occur in the male homologue derived from the distal part of the Müllerian ducts—i.e., the uterus masculinus—and histological evidence provided by some anomalous prostates from rhesus monkeys, that will be presented in detail elsewhere, favours the view that in this species sinus epithelium does in fact extend along and replace the Müllerian epithelium that forms the groundwork of the utricle. Far stronger support for this interpretation is provided by endocrinological evidence, not only from the rhesus but also from other species of monkey, for in them the vaginal and utricular response to oestrone is essentially similar to that of tissue undoubtedly derived from the epithelium of the urogenital sinus—i.e., in the female the epithelium of the vestibule, and in the male that of the urethra as far up as the opening of the utricle (which represents the external opening of the primitive Müllerian ducts). The facts thus suggest that in these species of monkey, the male oestrogenic responses under consideration do not fundamentally represent the responses to oestrogens of Müllerian epithelium, but of epithelium derived from the primitive urogenital sinus. Sinus epithelium reacts in essentially the same way as true ectodermal epithelium (see below), and although the epithelium of the urogenital sinus is generally regarded as being entodermal in origin, there is an alternative view, which has not been disproved, that ectoderm plays a large part in its formation (see Frazer,⁷ p. 432). The embryological topographical connexion between the urogenital sinus (as part of the original cloaca) and the primitive streak, the sinus's great sensitivity to oestrogens, and the primitive streak's capacity to elaborate organising substances, are facts which assume a related interest in view of the presumed chemical relationship between organising substances and oestrogens.⁸

The oestrogen-sensitive epithelium of the monkey is not limited to tissues derived from the urogenital sinus, but in many species extends for varying distances from the external genitalia to form a "sexual skin," a circumgenital area of surface skin which becomes highly coloured, thickens, and may even swell in response to oestrone. Although not so pronounced, the external epidermal growth is fundamentally the same, and may be regarded as part of the same process, as the more centrally occurring stratification of sinus epithelium; the external reactive area is the peripheral part of the total oestrogen-sensitive epithelial zone. If the extent of this zone in the female of a species is regarded as a species index of epithelial sensitivity to oestrone, an explanation is forthcoming for the fact that stratification of the male urethral epithelium in response to oestrone failed to occur in all species tested. In males, in which stratification did not occur, the corresponding females have no external sexual skin; in species in which the female has a sexual skin, stratification of the male urethral epithelium occurred.

IMPLICATIONS

The general hypothesis outlined here suggests that epithelial structures in whose development oestrogen-sensitive sinus epithelium has played a part should be expected to react when adequately exposed to the action of oestrogens. In the rhesus monkey, the urethral openings of the prostatic glands, which presumably give the topographical relations of the embryonic prostatic tubules, are placed almost entirely in the uppermost part of the region of the urethra which responds to oestrone. Nevertheless, only the proximal parts of the collecting tubules, and not the glands themselves, reacted in two monkeys of this species which were injected for 70 and 90 days respectively. It is possible that the glandular epithelium and the sinus epithelium, from which the glands arise, react differently owing to differential specialisation during development. On the other hand, it should be noted that the prostatic tubules of the mouse react only after very prolonged oestrone administration,¹ and it may also be remarked that true prostatic epithelium did show signs of reacting in two other species of monkey (*Cercopithecus mona* and *C. aethiops sabaeus*) after as little as two weeks' treatment.³ It is also of interest that one part of the human prostate, the posterior lobe, arises entirely from tubules which develop distal to the openings of the Müllerian and Wolffian ducts,⁹ and by analogy with the rhesus monkey, from the region of the urethra most sensitive to oestrogens. In view of the prevailing belief in the close chemical relationship of oestrogens and some carcinogens,¹⁰ it is therefore significant that although primary carcinoma may occasionally begin anywhere in an otherwise normal prostate,¹¹ it commonly starts in the posterior lobe.

A useful extension of the present hypothesis which should be mentioned here is that in species in which the uterus masculinus is an organ composed of a system of tubular glands only—e.g., man and *Presbytis entellus*—and in which it does not respond to oestrogens by epithelial stratification such as occurs in the rhesus monkey, the utricular epithelium represents Müllerian epithelium unchanged by epithelium of the urogenital sinus. There is some evidence, as yet unpublished, that the small columnar-celled glands occasionally found in the hydatid of Morgagni, the male rudiment of the cranial end of the Müllerian duct, develop and become distended in monkeys under the influence of oestrone; whether or not tubular glands derived from the terminal part of the duct would behave as uterine glands under the same conditions is at present a matter for conjecture. This problem has been considered elsewhere from the point of view of its possible bearing on the aetiology of senile hyperplasia of the prostate.¹²

The detailed data supporting the working hypothesis put forward here will be submitted for publication in the near future.

THE TREATMENT OF CARCINOMA OF THE COLON*

BY H. H. RAYNER, M.B. Vict., F.R.C.S. Eng.

SURGEON TO THE MANCHESTER ROYAL INFIRMARY AND CONSULTING
SURGEON TO THE MANCHESTER CHILDREN'S HOSPITAL

THE factors which govern our treatment of this grave disease are so numerous, yet so variable in their incidence and importance, that the problem of treatment differs greatly between one case and another. Personal experience then is apt to be an imperfect guide to the surgeon, and for that reason there are few subjects so worthy of discussion at a meeting of surgeons.

Preliminary Treatment of the Intestinal Obstruction

The large majority of patients when first seen by the surgeon are suffering from some degree of intestinal obstruction, and in a considerable proportion of these the obstruction is complete or acute and of several days' duration. It is one of the axioms of abdominal surgery that complete obstruction caused by colonic cancer must be relieved by simple drainage of the colon above the obstruction and that no attempt must be made to deal with the causative disease until the obstruction has been relieved and the patient has received the full benefit of preliminary drainage of the colon. The operation of caecostomy has for many years been that most commonly employed for this purpose, for it has the merit of being applicable to every case irrespective of the site of the growth if we exclude the caecum and ileocaecal orifice. It is clear that caecostomy is not the ideal operation for the relief of obstruction in the distal colon; but it works sufficiently well, for it can be depended upon to save the patient's life from the immediate threat of death from intestinal obstruction, and it is easy and safe to perform considering the circumstances. Above all, it leaves the field for the later operation of resection undisturbed and the surgeon unhampered. The choice of operation for this preliminary drainage is of the greatest importance; if the surgeon in his desire to achieve the ideal performs a colostomy near the obstruction he may later bitterly regret his choice. There is some divergence of opinion whether, in these cases of complete obstruction, the surgeon should proceed at once to perform a caecostomy through an incision directly over the viscus, or whether he should first explore the abdomen through a paramedian incision and then, unless the information he has thus obtained suggests a more effective operation, go on to perform a caecostomy.

There is room for both procedures, but personally I have a strong preference for an exploratory laparotomy unless the condition of the patient is desperate and makes the use of local anaesthesia highly desirable. If a spinal anaesthetic is to be employed—and this I believe to be the best for the great majority of these patients—then the duration of the anaesthesia will suffice for exploration and caecostomy and the complete relaxation obtained by this method will allow a gentle but efficient exploration and an easy closure of the incision.

The advantages of the exploratory incision are several. (1) The diagnosis of colonic obstruction can

* A paper read before the Manchester Surgical Society on Dec. 3rd, 1935.

be verified; there can be no risk of overlooking obstruction in the lower small intestine. (2) The information to be obtained about the site of the growth, its extent and connexions, the presence of metastases in the liver, enables one to decide whether cæcostomy is the best operation under the particular circumstances and on one's plans for the resection of the growth at a later date. An opaque enema examination, after recovery from the preliminary operation, will not give us all this necessary information. (3) If cæcostomy is decided upon the exploratory incision will often help us to perform this operation much more easily than could be done through a limited incision directly over the cæcum for blind cæcostomy is sometimes a very difficult operation.

Cæcostomy was performed on 28 of my patients and in 20 of these at the close of an exploratory laparotomy. Of these 20 one died; in this patient compression of the cæcal pouch (the cæcum had been brought up to the skin) by the parietal muscles obstructed the outlet and the recognition of this was too tardy to save life. In one of the 20 blind cæcostomy had been attempted, but an exploratory incision was necessary to expose and deliver the cæcum through the iliac incision. In the other 8 patients a blind cæcostomy was performed, and of these also one died; strictly speaking, this death did not follow a blind cæcostomy, but was due to my inability to perform it owing to the high position of the cæcum and extreme distension of small intestine. Rather than make an exploratory incision which would have allowed me the valuable alternative of a colostomy of the transverse colon (always an operation to keep in mind in the presence of pelvic colon obstruction—the site of the disease in this patient) I performed a Witzel's enterostomy of the terminal ileum which failed to give the patient more than very temporary relief.

Removal of the Growth and Adjacent Portions of the Colon

The patient should by preparatory treatment be made as fit as the circumstances allow to undergo this. Sometimes much can be done to reduce the degree of chronic intestinal obstruction, from which the patient in great probability suffers, by a fluid but nourishing diet, the judicious administration of liquid paraffin, Epsom salts, and small doses of morphia. During this preparatory treatment a systematic examination, including an opaque enema examination, will have revealed the position of the growth. If the patient has had complete obstruction then his preparatory treatment will have been facilitated by the drainage of the colon which the cæcostomy has secured, and by irrigation of the colon through the cæcostomy during the three or four days preceding the operation of resection. At this operation, presuming there is no contra-indication to resection, there are in principle two methods open to us: (a) resection and immediate union of the two ends by suture anastomosis, and (b) resection without immediate union. The bowel ends are brought up to the surface of the abdominal wound and continuity between these is later established by the enterotome as in Paul's operation and its modern counterpart, obstructive resection.

RESECTION WITH IMMEDIATE UNION

Probably most of us have performed resection and immediate anastomosis of the ends of the colon, even in the presence of a moderate degree of intestinal obstruction, without the safeguard provided

by a preliminary cæcostomy, and have had many gratifying successes from this procedure; but collective experience shows that such a method entails an unnecessary degree of risk and it should therefore only be practised under very exceptional conditions, including that of great skill and experience on the part of the surgeon. Resection and suture anastomosis should only be practised after a preliminary cæcostomy or some other type of proximal drainage, even though the growth may have caused little or no obstruction in the colon. The cæcostomy may be performed at the same time as the resection operation, but to me this does not seem as sound a proceeding as the performance of a cæcostomy two weeks before the resection. When the growth to be resected is in the pelvic colon then an additional safeguard is the passage of a wide-bore rubber tube up the anus to a point in the colon several inches above the anastomosis.

This principle of proximal drainage before resection and anastomosis is modified in the treatment of growths in the cæcum and proximal colon. Here the orthodox method of operation in two stages, first lateral anastomosis between terminal ileum and transverse colon, or, as advised by Rankin,¹ implantation of the end of ileum into the side of the colon, and then, some two weeks later, resection of the short-circuited bowel holding the growth, gives excellent results. Wakeley and Rutherford² recorded 14 such operations in series without a death. My only criticisms of the procedure are that both stages of the operation are serious ones, for in both the colonic lumen is opened and sutured, and then the second stage may be troublesome on account of plastic adhesions around the anastomosis.

RESECTION WITHOUT IMMEDIATE UNION

The second method, that in which after resection of the growth the bowel ends are brought up to the abdominal wound for restoration of continuity at a later date, was first described by F. T. Paul³ forty years ago. During the past twenty-five years the great improvements in technique of intestinal surgery have led to the pretty general adoption of resection and immediate suture anastomosis as the method of choice, and Paul's method has taken a place second to this and as one to be employed under exceptional circumstances. In recent years, however, there has been a distinct movement to revive Paul's method with improvements in technique under the term "obstructive resection." For those who may not be familiar with this method the following brief description is intended.

The length of colon to be resected is determined; its mesenteric attachments are divided so as to allow removal of a maximum amount of mesenteric tissue; above and below the colon must be extensively mobilised so as to allow the bowel ends to be brought up to the abdominal wound without tension, yet without sacrificing the thoroughness of the resection. Two crushing clamps (Schoemaker pattern) are then applied, about $\frac{1}{2}$ inch apart across the upper limit of the loop to be resected and two across the lower limit. (Fig. 1.) The resection is now completed by dividing the bowel with the cautery between each pair of clamps. The posterior peritoneal gap is repaired, and then the two limbs of the bowel are tacked together by the finest catgut sutures over a length of 3-4 inches from the clamps so as to produce the familiar double-barrelled gun arrangement. The bowel ends each firmly in the grasp of a crushing clamp are brought out through the abdominal wound which is closed snugly around

them. The skin edges around the emerging bowel should be sutured to the bowel wall at a few points in order to cover over the raw area and to prevent premature retraction. (Fig. 2.) The crushing clamps are removed on the third day and an enterotome is introduced then or on the following day to a depth corresponding to the length of coaptation of the two limbs of bowel. (Fig. 3.) The enterotome should at first be screwed just tightly enough to afford a firm grip of the partition, and is gradually tightened up during the next two days. A lengthy communication between the two limbs of the colon is crushed out in six or seven days and usually a natural bowel action through the rectum follows within a day or two. The faecal fistula that remains tends to shrink and the amount of faecal discharge to diminish; the operator may close the fistula by an extraperitoneal operation at his own discretion.

This method may be employed for the resection of any part of the colon except of course the lower pelvic colon, for here the lower stump of bowel is too short to allow of its being brought up to the abdominal wound. Difficulty too will be experienced at the upper end of the pelvic colon, particularly in stout patients, for the absence of a proper mesentery to the iliac and descending colon may limit the length of the upper stump and tension or insufficient length of resection must not be tolerated as a means of securing coaptation of the two limbs of bowel. Under these circumstances either the ends of the bowel should be brought out of the wound without attempting to coapt them, and later, when the bowel is healthy and the patient is in good condition, the ends can be united by intraperitoneal suture, or the abdominal wound should be prolonged to allow of resection of the descending colon and splenic flexure in order that the transverse colon may be utilised as the upper limb in the wound. Obstructive resection can be used very satisfactorily for cancer in the proximal colon.

I have performed by this method right hemicolectomy in 8 patients without a death or serious complication; the discharge of ileal contents on to the abdominal wall for some two weeks after the operation may seem a serious objection to the method in this situation but in practice I have seen no harm result from this and the inconvenience is no greater than that after an open caecostomy. Obviously this method should not be practised on a patient suffering from a complete or acute obstruction, but it may properly be performed after a preliminary caecostomy, distasteful as it may seem to inflict for a time two separate faecal fistulae on the patient. It may be employed in patients suffering from chronic intestinal obstruction without preliminary caecostomy, and in these the colonic contents should be displaced from above downwards into the loop to be resected before the application of the upper crushing clamps, or, if this is insufficient to relieve the loaded colon, then after completion of the operation and protection of the wound the clamp can be removed from the upper limb of bowel and a tube tied into the end. To facilitate this the upper limb should be arranged to project 2 or 3 inches beyond the surface of the abdomen; this loop with its attached tube can then pass through the dressings and fastenings. Lahey⁴ applies this method of securing immediate drainage of the proximal intestine to resection of the right colon in the presence of intestinal obstruction and I am satisfied that the method is a valuable one under these conditions, and is always practicable because the upper limb is obtained from the terminal ileum.

The following advantages of obstructive resection will be readily appreciated.

1. The operation is much shorter in duration and easier. This is a substantial merit if the patient is a stout person whose colon is difficult of access and whose mesenteries are heavily fat laden. Under such conditions resection and anastomosis is a long and laborious operation and is often followed by severe shock; the operator too is tempted to hurry over the resection stage because of the amount of work that still remains to be done. In the obstructive method, as Devine⁶ points out, almost the whole of the operator's time and care are spent on the essential part of the operation—the complete removal of the malignant growth and its connexions. For these reasons the method should always be employed when the resection is a complicated one involving other viscera or the parietes.

2. The operation with ordinary care is an aseptic one, and the operator cannot fail to be struck by the clinical evidence of this.

THE METHODS COMPARED

How do these methods compare, and why has Paul's method in a modified form been revived? Resection and suture anastomosis at its best gives a very good result with a shorter and pleasanter convalescence than the obstructive method with its faecal fistula and the secondary operation for the closure of this. The fundamental objection to suture anastomosis after resection is the high mortality and morbidity-rate which it entails in the hands of most surgeons. To quote from my own experience—in 39 operations of resection and anastomosis there were 9 deaths (21 per cent.), and amongst the patients who recovered there were several whose convalescence was marred and protracted by wound suppuration, faecal fistula, and illnesses arising from these complications. In 30 consecutive resections performed by obstructive resection there were 3 deaths (10 per cent.), and very few complications of any kind amongst the patients who recovered.

I do not attach much importance just to the contrast between the two mortality-rates for each series is a small one; but a consideration of the modes of death and of the difference in the convalescence after the two methods, in conjunction with the contrast in mortality-rate, does suggest

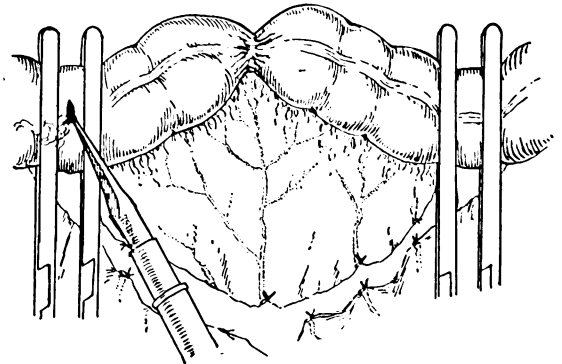

FIG. 1.—Obstructive resection. Division of colon with cautery between crushing clamps.

that obstructive resection is a valuable method, and one always to keep in mind at least as an alternative to resection anastomosis.

Of the 9 deaths in the resection anastomosis series, 2 occurred within two days of the operation and were plainly due to the severity of this; both patients were stout and had deep abdomens and in 1 a previous colostomy near the growth increased the magnitude of the operation. The other 7 all made good recoveries from the operation and made satisfactory progress for at least four days; after

that time relapses occurred, sometimes sudden in onset with severe abdominal pain and rapid collapse—plainly due to gross leakage at the anastomosis—in others less sudden with rise of pulse-rate and temperature, abdominal discomfort evidence of wound infection, and later faecal discharge and progressive cardiac muscle failure.

Of the 3 deaths after the obstructive method 2 were caused by acute intestinal obstruction beginning three or four days after operation; in one of these a large portion of the anterior abdominal wall had been removed with the growth and probably the small intestine became adherent to the raw area which inevitably resulted; in the other, obstruction was due to the small intestine becoming trapped in the foramen created by bringing up the stumps of the pelvic colon to a left iliac incision. The third death was due to faulty application of the enterotome which was screwed up much too tightly when first inserted. Severe abdominal pain and collapse followed in a few hours, but as the patient was known to have gross metastases in the liver no further operative interference was attempted.

The 3 deaths after Paul's operation do not seem to me to be due to defects inherent in the method, whereas the 9 deaths and the protracted convalescences in some of the survivors after suture

FIG. 3.—Obstructive resection. Re-establishment of continuity of colon by crushing intervening bowel walls with enterotome.

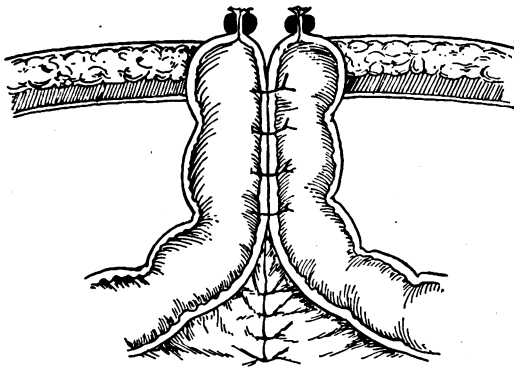

FIG. 2.—Obstructive resection. Coaptation of terminal limbs of colon by sutures: ends of colon, each in grasp of a crushing clamp, fixed in abdominal wound.

anastomosis can hardly be dismissed as due to avoidable or very unusual causes. Seven of these deaths were unmistakably due to leakage or gross infection at the anastomosis, and in view of the interval of time (four days at least) between the operation and the onset of the first symptom, it may be inferred that the infection originated within the bowel and travelled through anastomotic margins devitalised by suturing.

The risk of infection and leakage at the anastomosis, after the mechanical support of the sutures has ceased to be effective, remains inherent in all suture anastomoses of a functioning colon; particularly so in cancerous obstruction, for here the bowel wall in the vicinity of the growth is infected and the stagnant faecal contents are abnormally virulent in their toxicity. A proximal fistula (caecostomy) will by diverting a portion of the faecal stream and flatus relieve the anastomosis of some of the strain to which otherwise it would be subject, and by allowing the means for a previous cleansing of the colon will have reduced the toxicity of the contents, but the extent of this relief in any particular case is uncertain and cannot be depended upon to abolish the risk of infection and breakdown of the anastomosis.

Resection of Growths in the Lower Pelvic Colon

In the lower pelvic colon, after an adequate resection of the growth, the lower stump is too short to permit of a reliable suture anastomosis and obstructive

resection is still less practicable. A large number of operations have been devised to meet the problem; some of these are chiefly noteworthy as tributes to the endurance of the human species. I shall mention four: the first two are suitable for growths at or near the pelvirectal junction, one of them entailing a permanent colostomy, while the other does not; the second two are suitable for growths a few inches above the pelvirectal junction, and of these again only one entails a permanent colostomy.

1. *Abdomino-perineal excision of the rectum.*—A well-established operation the merits of which it is unnecessary to describe.

2. *Abdomino-anal excision of the rectum* in which the stump of the pelvic colon is pulled through the anal sphincters—after removal of the rectum and the mucosa of the anal canal—to the site of the anal orifice. A description of this operation, as performed by Prof. Sebrecht, of Bruges, was given by me at a recent meeting of the proctological section of the Royal Society of Medicine⁶ and was severely criticised on the ground that it entailed a serious risk of sloughing in the transplanted colon.

3. *Anterior or intraperitoneal resection of the rectum.*—In this operation after the necessary resection of bowel the stump of the rectum is invaginated, dropped into the bottom of the pelvis, and is covered over by suturing the gap in the peritoneal floor of the pelvis. The end of the pelvic colon is brought out through a small left iliac incision as a terminal colostomy. This operation, though a very safe one, is open to the criticism that the patient is left with an intact but functionless sphincter mechanism around the anal canal.

4. The *Rutherford Morison type* of operation in which a direct union between the open ends of the pelvic colon and the stump of the rectum is effected over a wide bore tube. One end of the tube must be secured in the end of the pelvic colon by a transfixion ligature and the other end is passed into the rectum through the anus, where it is drawn down by an assistant. Continuity of the bowel ends can now be restored by invagination and sutures.

Before undertaking either of the two operations which aim at reconstruction of the rectum—the abdomino-anal and the Rutherford Morison types—the surgeon will be well advised to carry out a colostomy of the transverse colon some three or four weeks previously. The colostomy should be of the Sistrunk type, in which the ends of the colon are completely separated by a bridge of skin. I began to perform such a colostomy in this connexion 3½ years ago and have never since omitted to do it before attempting reconstructive operations on the lower pelvic colon and

rectum. Devine⁷ has described and advocated a colostomy of the transverse colon as an essential preparatory measure to all anastomosis operations on the lower pelvic colon, and the surgeon who is unaware of the value of this step should acquaint himself with Devine's convincing article on the subject. A colostomy of the transverse colon in which the ends are effectively divorced prevents faecal material entering the colon distal to the colostomy; by daily irrigation it allows the removal of faecal material already present and the cleansing of the colonic mucosa; further, it puts the distal colon entirely out of action until complete healing of the transplanted bowel has taken place. It can be easily closed afterwards by the enterotome.

The danger of all anastomosis operations in this region is that of sloughing of the bowel, and this is due to the combined effects of infection from the faecal traffic and impairment of blood-supply from suturing and encroachments on the mesentery; remove the infective element entirely and the impairment of blood-supply loses most, if not all, of its terrors for the surgeon.

THE PRODUCTION OF A NEUROTROPIC STRAIN OF RIFT VALLEY FEVER VIRUS

By R. D. MACKENZIE, M.B., F.R.C.P. Edin.

AND

G. M. FINDLAY, C.B.E., M.D., D.Sc. Edin.

(From the Wellcome Bureau of Scientific Research, London)

SINCE Pasteur first showed that the street virus of rabies can be altered by continued passage in the brain of the rabbit, much evidence has accumulated to show that other viruses may be experimentally modified by changing the substrate on which they grow. Thus, Theiler (1930) found that the virus of yellow fever was modified by passage in the brains of mice, and that eventually its capacity to produce viscerotropic lesions in rhesus monkeys was practically abolished. Nieschulz (1932) and Alexander (1933) similarly produced a neurotropic strain of horse-sickness virus by repeated mouse brain passage. These efforts at modifying the characteristics of viruses involved the use of an animal which is not normally susceptible to the ordinary strain of the virus. Recently, however, Findlay and Stern (1935) have shown that it is possible temporarily to inhibit certain virus activities by means of the protective action of immune serum. When rhesus monkeys were injected intraperitoneally with yellow fever immune serum, before inoculating the ordinary yellow fever virus intracerebrally, it was found that the animals died, not with necrosis of the liver, but from encephalomyelitis, thus demonstrating the essential neurotropism of the yellow fever virus. In view of the result obtained in yellow fever, it appeared not improbable that a similar method might reveal a neurotropic activity in certain viruses, which

so far had shown only viscerotropic characters. Further, it seemed possible that intensive passage under these conditions might result in the production of a neurotropic fixed virus variant.

In the present communication the results are recorded of applying this experimental procedure to the virus of Rift Valley fever.

THE VIRUS

Before describing the production of a neurotropic strain of Rift Valley fever virus, it may be of interest very briefly to recall the main facts in regard to the ordinary or viscerotropic strain. The virus was first isolated by Daubney, Hudson, and Garnham (1931) in Kenya where it caused a great mortality of ewes and lambs; it was also found to be pathogenic for man, producing a dengue-like disease, but without any rash. Findlay and Daubney (1931) showed that mice and other small rodents are particularly susceptible to the virus, since they die with widespread necrosis of the liver a few days after inoculation, while rhesus and other monkeys develop a non-fatal febrile reaction, not unlike that seen in man, associated with focal necrosis of the liver (Findlay 1931-32 and 1932-33). The virus has now been maintained for nearly five years under laboratory conditions, and during this period has never shown any signs of neurotropic activity; it has maintained unimpaired its pathogenicity both for men and mice. In the latter species, an intraperitoneal inoculation of 0.2 c.cm. of a liver suspension diluted 10^{-9} or 10^{-10} is almost always fatal. Death with liver necrosis also follows intracerebral or intranasal inoculation.

THE NEUROTROPIC STRAIN

Despite the great susceptibility of mice to the ordinary or viscerotropic strain of the virus, it has proved comparatively easy to produce a neurotropic strain in this species, the technique employed being based on that used by Findlay and Stern (1935) in the case of the yellow fever virus. Mice were first injected intraperitoneally with human immune serum derived from a recent laboratory infection. Fifteen minutes later they were inoculated intracerebrally with 0.03 c.cm. of blood from a mouse dying of Rift Valley fever. In the case of the first transfers the mice were killed 2-3 days after inoculation when the infected brain tissue was passaged. Later the mice were allowed to develop nervous symptoms, which usually came on 3-5 days after intracerebral inoculation and consisted of paresis of the hind and fore legs, circular turning movements and epileptiform crises. One strain which has passed through more than thirty intracerebral passages shows all the features of a fixed neurotropic variant. The symptoms exhibited by the mice have all been referable to the central nervous system, while the lesions present have been those characteristic of a meningoencephalomyelitis, destruction of neurones, perivascular infiltration, with slight involvement of the meninges, and occasionally extensive necrosis of the brain substance. In certain nerve-cells intranuclear inclusions have been found, very similar to those produced by the neurotropic strain of yellow fever virus. In the earlier passages, in addition to these nervous changes, certain mice exhibited small areas of focal necrosis in the liver, though the widespread damage characteristic of the viscerotropic strain was absent; hæmorrhage in the stomach was not found. In later passages, the lesions are confined to the central nervous system. After intraperitoneal inoculation of the neurotropic strain, the virus circulates in the

blood stream for a few days, then tends to localise in the spleen. Quite frequently, however, and certainly more often than is the case with neurotropic yellow fever virus, adult mice inoculated intraperitoneally have developed nervous symptoms. Intraperitoneal inoculation accompanied by cerebral trauma localises the virus in the brain as in the case of yellow fever. Intranasal instillation of the neurotropic virus in mice is also followed by the development of encephalitis.

Rats, field voles (*Microtus agrestis*), and ferrets have developed encephalitic symptoms after inoculation with the neurotropic strain of Rift Valley fever virus.

When rhesus monkeys are inoculated with the viscerotropic strain of Rift Valley fever virus, whether by the intraperitoneal, intracerebral, or intranasal route, they have never developed anything more than a short febrile reaction, and histologically have merely exhibited focal necrosis of the liver. When, however, they are inoculated intracerebrally with the neurotropic strain, death has invariably resulted with the symptoms and lesions of encephalitis. The same result has been obtained after intranasal instillation. If the virus has been inoculated intraperitoneally without cerebral trauma, no reaction has occurred, though immunity has subsequently developed; when, however, an intracerebral injection of starch has accompanied the intraperitoneal inoculation, encephalomyelitis, as in the case of mice, has followed.

The pathogenicity of the virus for monkeys is thus decreased when the intraperitoneal route of inoculation is alone employed, but increased when the virus is given the opportunity of obtaining access to nervous tissue.

The reaction of sheep and lambs to the neurotropic strain of Rift Valley fever virus is at present under investigation.

SUMMARY AND CONCLUSIONS

A neurotropic strain of Rift Valley fever virus has been produced in the mouse. After more than 30 passages, it has become "fixed" for nervous tissue and when inoculated intracerebrally it always produces encephalomyelitis in mice with an absence of liver necrosis.

Rhesus monkeys also succumb to encephalomyelitis when inoculated intracerebrally or intranasally with the neurotropic strain of Rift Valley fever virus. When inoculated intraperitoneally they exhibit only a very slight febrile reaction unless the central nervous system is at the same time traumatised; they then develop encephalitis.

The production of a neurotropic form of Rift Valley fever virus in a highly susceptible animal, by means of the restraining action of immune serum, opens up the possibility of producing similar variants in the case of a number of other viruses. It also offers a possible explanation of the occurrence of nervous sequelæ in certain virus infections which do not ordinarily involve the central nervous system.

AN OPERATION FOR HYPOSPADIAS

BY DENIS BROWNE, F.R.C.S. Eng.

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON

In common with many others, I got my first understanding of hypospadias and my first successes in its treatment by following the teaching of Edmunds.¹ For the first time he described the separate elements of the deformity, gave rational ways of overcoming them, and convincing proof that these ways could be successful. I think, however, that I am not alone in finding two objections to the technique he describes. The first is that it is difficult both to understand and to perform; even when one has obtained a mental image of exactly what one intends to do, the right arrangement of the "dog-ear" flaps so that they shall lie under even tension all over needs experience as well as a good dressmaker's eye.

The second objection is more important: it is that there is one weak spot in the new urethra, the point where the deep and superficial lines of sutures cross. Here there is a short direct outlet for urine passing along the channel, only controlled by what-

FIG. 1.—Outlining of incision for transplantation of prepuce. (a) Split down dorsum of penis. (b) Incision along outer edge of hood of prepuce. (c) Outline of glans seen through prepuce.

ever immediate adhesion there may be in the sewn skin edges; and it is here that a sinus not infrequently forms, needing a secondary operation for its closure.

I believe the following procedure, admittedly based on Edmunds's technique, is easier to understand and perform, and less liable to fistula formation. I derived it from considering that if one had to make a tube like the urethra on any plane surface of the body, and had unlimited skin to do it with, there would be one obvious method of choice. This would be to cut out a flap of skin alongside the floor of the new passage, to turn this skin back and suture it to form a tunnel, and then to cover in the raw area left by pulling across it another and larger flap from the other side. From a tube formed in this way there could be no direct exit for fluid at any point, as the two lines of sutures lie far apart, and in consequence the probability or primary complete healing would be very high.

In the penis of hypospadias there is of course not nearly enough skin to allow of this being done without dangerous tension; but there is close by a sufficient available reserve in the prepuce. Where my method differs from that of Edmunds is that instead of dividing this skin into two and swinging each half round underneath, I transplant it back up the dorsum of the penis, and so free the original skin

¹ THE LANCET, 1926, i., 323.

FIG. 2.—Prepuce dissected up and split into a ribbon ready for transplanting into the bare area left by the retraction of the edges of the dorsal incision on the penis. (a) Bare area on penis. (b) Original tip of prepuce.

of the sides and back for the simple tunnel formation I have described. I have sometimes tried to explain the idea by comparing it to the changing of a single-breasted coat into a double-breasted one; the necessary fullness for the overlap being given by the insertion of a new piece of material down the middle of the back.

TECHNIQUE

1. *Transplantation of the prepuce.*—An incision is made straight down the dorsum of the penis from its root to the base of the prepuce. Here it diverges to either side along the sides of the "hood," running about two-thirds of the way along the sides of this.

FIG. 3.—Dorsal view of penis after transplantation of the prepuce. (a) Original tip of prepuce. (b) Apex of dorsal incision.

The two layers of skin in the hood are then separated, so that a single broad ribbon is produced; this is done very gently, as much as possible by blunt dissection without injuring the large veins. There is no objection to leaving a loose sack of skin where the tip of the prepuce originally lay.

The dorsal incision retracts into a wide gap as soon as it is made, and into this the ribbon is now fastened by vertical mattress sutures, with its pointed tip fitting comfortably into the beginning of the cut at the root of the penis.

2. *Straightening the penis.*—This most important

FIG. 4.—Outlining of flaps for making new urethra. (a) Opening of urethra. (b) Incision freeing lining of new urethra. (c) Incision freeing flap that will cover the raw area left by forming new urethra.

FIG. 5.—Appearance when the new urethra has been formed, but not yet covered in. (a) Outer flap raised, ready to be pulled across the raw area. (b) Line of continuous Connell type stitches forming new urethra. (c) Gutter showing line of reflexion of inner flap. (d) Catheter in urethra.

step in the operation is done exactly as described by Edmunds, either at the same time as the implantation of the prepuce, or later. The whole of the fibrous band which ties the penis into a permanent chordee shape in any marked degree of hypospadias is freed from the body and allowed to retract towards the base, carrying with it the urethral opening, which thus comes to lie much further away from the glans than it did originally. The raw gap so left is easily covered in from the sides owing to the relaxation given by the dorsal insertion. This

FIG. 6.—Appearance at end of operation. (a) Deep line of sutures, shown as if visible through skin. (b) Superficial vertical mattress sutures.

straightening of the penis should be done early in order to allow of its proper development; some time during the second year is a suitable time, as before that the small size of the parts makes operating very difficult.

3. *Construction of urethra.*—About the age of four is a suitable time for this. It should never be done till at least six months after the first operation, in order to let the penile skin regain its normal elasticity and looseness.

Two longitudinal incisions outline the skin which

FIG. 7.—Approximate lines of sutures in Edmunds's operation. (a) Deep line of sutures. (b) Superficial line of sutures. (c) Weak point in floor of new urethra where the two lines of sutures cross.

will form the new urethra, that on the side from which the inner flap is to be raised being naturally further from the mid-line than the other. Each flap is freed by lateral cuts to appropriate distances at the top and bottom of each incision, and they are gently dissected up. A small rubber catheter is now passed, lubricated with 1/1000 flavine in paraffin, and over it the inner flap is turned back and sutured in position by a continuous catgut suture. This suture should be of the Connell type, only picking up the deep surface of the skin, and not penetrating to the lumen of the new urethra, so that no suture can convey urine into the tissues by capillary attraction. It seems to me that this lateral line of non-

FIG. 8.—Diagram of connexion of pinhole meatus and blind sinus in first degree hypospadias. (a) Opening of blind sinus. (b) End of sinus. (c) Pinhole opening to urethra. (d) Tissue divided to connect openings. (e) Urethra.

penetrating continuous suture must be considerably more waterproof than the median interrupted stitches tied in the lumen of the urethra which are used by Edmunds. The outer flap is then sewn into position by vertical

mattress stitches, and it will be seen that the two suture lines lie far apart. At the only point at which it may look that they would coincide, just below the original opening, the retraction of the scrotal skin ensures a wide difference of line. For all the stitching I use a suture which I originally got Messrs. Armour and Co. to make for intestinal anastomoses in infants, a very fine straight round-bodied eyeless needle carrying 6/0 chromic catgut.

The catheter is left in for twenty-four hours. This is not long enough to start a urethritis, but allows time for the coagulation of the tissue juices to seal the wound and waterproof it against the flow of urine.

RESULTS

I have tried this method on eight cases, all of which have healed by first intention without a fistula. I have also used it successfully in a reversed form for a case of epispadias, transplanting the apron-like prepuce found in this condition into the ventral surface of the penis, and then covering in the deep urethral gutter with a double flap of the kind described. (The split glans can be easily closed by simple rawing and suture of its dorsal edges.)

A NOTE ON FIRST-DEGREE HYOSPADIAS

A quite common deformity is that in which the urethra ends in a pinhole meatus within the V-shaped area of skin under the glans. A formal plastic operation of the kind described would be quite useless, even if possible. The only disability is that the flow of urine, although delivered to almost the right place at the tip of the penis, dribbles downwards instead of spurting forwards owing to the opening being a pinhole on the floor of the urethra. Now it is a curious thing that in many of these cases there is a blind sinus lined by mucous membrane opening closer to the end of the glans, and running backwards

half an inch or so, deep to the urethra proper. I have in three cases of this sort connected the two openings by passing one blade of a small blunt-pointed scissors into each and cutting the tissues between. The rather free bleeding resulting can be controlled by stitches passed with the fine needle described. The results have been excellent. The advantage of enlarging such an opening towards its normal situation instead of away from it is obvious, and there is no tendency to stenosis.

PNEUMOCOCCUS MENINGITIS FOLLOWING TONSILLECTOMY AND TERMINATING IN RECOVERY

BY STANLEY E. HARRIS, M.D.

OF PHILADELPHIA, PA.; AND

H. A. YENIKOMSHIAN, M.D. Beirut, M.R.C.P. Lond.,
D.T.M. & H.

ASSOCIATE PROFESSOR OF INTERNAL MEDICINE, AMERICAN
UNIVERSITY OF BEIRUT, SYRIA

PNEUMOCOCCUS meningitis may either be a primary infection, or, more commonly, an extension from a focus elsewhere in the body. In most of the recorded cases it has followed infection of the ear or pneumonia. Since we have been unable to find other mention of this condition as a complication or sequela of tonsillectomy, and because recovery from proven pneumococcus meningitis is rare, we are reporting the following case.

CASE RECORD

A pupil nurse, aged 25, was admitted to the Hospital of the American University of Beirut on Feb. 25th, 1926, for tonsillectomy. She had suffered from rheumatic heart disease since an attack of polyarticular rheumatism in 1913. In 1916 her tonsils were clipped (guillotine operation), but the stumps were grossly diseased, and she had continued to suffer from occasional sore-throats and exacerbations of joint pain. The tonsillar stumps were removed under local anaesthesia, and after six days of uneventful convalescence she was discharged with a normally healing throat.

On the same afternoon, March 3rd, she began to have headache which was not relieved by aspirin and phenacetin, and her temperature rose to 38° C. (100.4° F.). These symptoms persisted till March 6th when the temperature rose to 40° C. (104° F.) and she was admitted to the medical service complaining of extremely severe, bursting headache, diplopia, and projectile vomiting. On examination she was found to be drowsy, but could answer questions intelligently when aroused. There was slight ptosis of the right upper lid and the right external rectus muscle was weak, causing strabismus. The pupils were equal and reacted to light and in accommodation. Slight muscular twitchings were noted over the face. Except for a few whitish spots over the fauces the pharynx and the mouth were negative. There was no glandular enlargement. The area of cardiac dullness was increased and a loud, rough systolic murmur was present at the apex and transmitted to the axilla. The pulmonary second sound was accentuated. The lungs were negative. There was no abdominal tenderness or rigidity, and no organs were palpable. The abdominal reflexes were very brisk. The left knee-jerk was more active than the right. Kernig's sign was present and there was moderate stiffness of the neck. There was no Babinski reflex.

Lumbar puncture was done at once, turbid spinal fluid being obtained under considerable pressure. Polyvalent antimeningococcus serum was injected, 60 c.cm. intrathecally and 40 c.cm. intramuscularly. When examined the fluid showed a cell count of 540 leucocytes per c.mm.,

85 per cent. being polymorphonuclears and 15 per cent. lymphocytes. The globulin content was increased; the sugar reduced to 37.7 mg. per 100 c.cm. Smears revealed numerous encapsulated Gram-positive lanceolate diplococci, and on planting the fluid in various media organisms having all the cultural characteristics of the pneumococcus were grown. Unfortunately no serum was available for typing, but the bacteriological characteristics were not those of Type III.

For three days there was no change in the symptoms, the patient crying out almost constantly, owing to the unbearable headache. On March 8th another lumbar puncture was done, purulent fluid was drained off, and 20 c.cm. of polyvalent antipneumococcus serum was given intrathecally. The spinal fluid again contained pneumococci on smear and culture. Antipneumococcus serum, 20 c.cm., was given intramuscularly and on the following day 20 c.cm. of 1 per cent. Mercurochrome intravenously. A very severe reaction followed this last injection, the temperature rising to 41°C. (105.8°F.); the patient went into collapse. Next morning, the 10th, her symptoms were much improved. Lumbar puncture yielded 30 c.cm. of fairly clear fluid which was replaced by 20 c.cm. of antipneumococcus serum, another 20 c.cm. being given intramuscularly at the same time. Improvement continued, no further specific treatment was given, and except for urticaria which appeared on the 11th her progress to recovery was uneventful. She was discharged cured on March 25th, soon took up her duties in the training school and completed her course without further illness.

DISCUSSION

It has long been the consensus of medical opinion that the prognosis of meningitis due to the pneumococcus is extremely unfavourable if not hopeless. Schottmüller¹ reported 100 per cent. mortality in 100 cases, and more recently Davidson and Wollstein² have reported a series of 122 cases in children without a single recovery. Although admitting that some patients have recovered, Waterfield³ in a review of 24 fatal cases at Guy's Hospital is frankly sceptical concerning the diagnosis in the more than 150 "proven cases with recovery" collected from the literature by Goldstein and Goldstein⁴ in 1927. In many of these cases, and in a few presented since that time, insufficient data are given concerning the methods used in identification of the causative organism or, as in the case reported by Goldstein and in those of Croft,⁵ and of McAuley and Hilliard,⁶ no growth was obtained on culturing the spinal fluid, the diagnosis being based on the finding of organisms resembling the pneumococcus in stained smears. Nevertheless, in a not insignificant number of the older cases and in at least 17 of the more recent reports, the diagnosis was sufficiently established by bacteriological studies for the prognosis in future to be less gloomy.

In these 17 cases pneumococcus Type I. was found in three instances⁷; in two the organism was of Type III.⁸; in three of Group IV.⁹; and in the remainder¹⁰ the type was not noted. It would appear that when recovery has occurred the causative organism in most instances has belonged to a relatively avirulent strain of the pneumococcus. A review of the therapeutic measures employed suggests that the second important factor leading to recovery is the vis medicatrix naturæ.

Since antipneumococcus serum became available it has been employed in the treatment of many cases, occasionally with favourable outcome. Reveno and McLaughlin⁷ gave large doses of specific serum intrathecally and intravenously with favourable results in their case of Type I. pneumococcus meningitis. In the 9 other cases collected from the recent literature,¹¹ and in our own case, where antipneumococcus serum was used, its rôle in bringing

about recovery is open to question. In none of them was the serum known to be type-specific. In several cases very small doses were employed and the relationship between serum administration and clinical improvement is not clearly shown. Repeated lumbar puncture is another procedure which has been often carried out. In 9 of the 17 cases¹² referred to, it was the chief method of treatment. Combined cisternal and lumbar puncture and cisterno-lumbar irrigation with normal saline solution was done in two of them.

Other therapeutic measures which have been advocated have either failed in other hands to give the results suggested by their proponents or have not been accorded sufficient clinical trial for judgment to be passed upon their efficacy. Among these may be mentioned ethyl-hydrocupreine (Optochin Base) and its soluble hydrochloride which gave much promise experimentally and which have been widely used¹³; hexamine (urotropine), which Murphy¹⁰ gave to his patient in large doses and to which he thought the rapid relief of symptoms might be attributed; potassium permanganate solution, which was administered by Weinberg⁸ according to the Nott technique as almost the sole treatment.

Mercurochrome has not proved effective either experimentally or clinically against the pneumococcus. In a case reported by Stoessiger,¹⁴ in which Gram-positive diplococci resembling pneumococci were found in the spinal fluid, mercurochrome was given intraspinally, and the patient "was on the road to recovery" after the third injection. In his case as in ours a severe reaction with considerable rise in temperature resulted from the mercurochrome injection. It is interesting to speculate whether in both cases the shock and temperature elevation did not play a part in inducing the favourable outcome.

EAST LANCASHIRE WORKPEOPLE'S HOSPITAL FUND. This fund is making excellent progress, for the cost of working is very small and the bank interest almost covers the expenses. Over £150 more is available for distribution than last year and the fund has been able to help several medical charities in Blackburn.

STREPTOCOCCAL SEPTICÆMIA TREATED WITH WHOLE-BLOOD INJECTIONS

By J. A. HENDRY, B.Sc., M.B. Aberd.

PHYSICIAN TO THE DEVONSHIRE ROYAL HOSPITAL, BUXTON; AND

G. J. GRIFFITHS, B.Sc., M.B. Lond.

PATHOLOGIST TO THE HOSPITAL

MUCH has been written on the use of streptococcal antiserum in the treatment of septicæmia. On the whole the results have not been satisfactory, although in the treatment of puerperal sepsis Burt-White¹ reported successes and in two cases recorded by Pinnock and Sanguinetti² good results followed the use of streptococcal antitoxin.

Human blood-serum was used by Lazarus-Barlow and Blayney Chamberlain³ in the treatment of septicæmia and they report success in 9 out of 12 cases. They suggest the use of whole blood in place of serum, and we adopted this method in the present case because the patient was seriously ill and it seemed inadvisable to remove her to hospital. The procedure used was the injection of 15 c.cm. of whole blood taken from the patient's husband and its immediate injection into the thigh. No apparatus was required other than sterile needles and syringe; nor was blood-grouping necessary.

CASE RECORD (SEE CHART)

While nursing her only child, who had a sore-throat, Mrs. A., aged 30, developed tonsillitis which lasted two days. This was on Oct. 24th, 1934. A week later sore-throat again developed, and on Nov. 7th it became serious; when the patient was seen by one of us (J.A.H.) her temperature was 101°F. and her pulse-rate 120, the tonsils and pharynx looking shiny and red. On Nov. 10th she became delirious, with terrifying dreams at night. Red raised patches appeared on the left side of the forehead, the right supraclavicular region, the right upper arm, the right wrist, and the right thigh above the knee. There was general stiffness but no meningismus. The temperature was now 104°F. and the pulse-rate 140. A blood culture was taken and the urine examined, the latter being found to contain red blood-cells, slight excess of leucocytes, and an occasional cellular cast. Streptococcal antitoxin (10 c.cm.) was given, with a further 10 c.cm. next day when the blood culture showed a short-

chain streptococcus. The antihæmolytic titre of the serum was 75 units (maximum normal 50 units).

On Nov. 12th the condition remained serious. There were severe headaches, the red patches noted on the 10th were more pronounced; also there was apparent rigidity of the upper and lower limbs. Antitoxin (20 c.cm.) was again given, and a further 30 c.cm. on Nov. 13th. From the 14th–23rd there was no improvement. The patient became emaciated and depressed and lost appetite. Her heart was enlarged and there was a systolic mitral murmur. An abscess appeared over the right wrist and it was incised on Nov. 23rd, a culture being taken at the same time. This was found to contain hæmolytic streptococci, and they were sent to Dr. F. Griffith, of the Ministry of Health, who reported that the organism was of the Carter type. He mentioned that this type had been isolated in a family outbreak in which a child died of acute peritonitis following a labial infection, the mother finally recovering after severe cellulitis in the region of the breast. A vaccine was prepared from the streptococcus, the strength being 100 million per c.cm., and this was given to the patient's husband on alternate days until the dose was 100 million, the object being to give the patient an immuno-transfusion.

On Nov. 27th an abscess over the right shoulder was opened; pus poured freely from it. For a time the patient's condition improved, but it deteriorated on the 30th; the headaches returned and she became depressed and exhausted. On Dec. 2nd another abscess, on the left arm, was incised and the patient received the first injection of husband's blood (15 c.cm.). The same quantity was given next day, and at 2 p.m. the temperature was normal, the maximum evening temperature being 100°F. A further 15 c.cm. was given on the 4th; there was general improvement, and the patient was free from headaches and able to take more food. Progress was interrupted, however, on the 10th when the temperature rose to 104°F., and on the 11th the state of affairs was not satisfactory, the patient being restless and depressed. An injection of 15 c.cm. of whole blood was given and another next day, when the maximum temperature was 102°F. and redness and swelling were apparent above the right knee, with stiffness of the joint. Fluctuation was obtained above the right knee on the 13th and an incision was made, but no pus was found. Injections of blood (15 c.cm.) were again given on Dec. 13th, 15th, 18th, and 24th, and a further incision was made about the middle of the thigh on its inner side. On the 25th, when the patient received a further dose of blood, pus was discharging freely from right thigh and she felt much better. The last blood injection was given on the 27th, when improvement was fully maintained, and on the 28th all incisions

showed signs of healthy healing. The maximum temperature was 99° F.

From Dec. 28th onwards the patient made good progress and on Jan. 21st she was convalescent. When seen on April 27th after a stay in Ireland she had put on over a stone in weight and there were no signs of residual infection. The antihæmolysin titre had risen from 75 units at the onset of the infection to 250 units on April 27th.

Although in this case there was a slight fall in temperature after each injection of streptococcal antitoxin, there was little improvement clinically. This may have been due to the absence from the antiserum of the specific antibody corresponding to the bacterium infecting the patient. Each injection of whole blood from the donor immunised with an autogenous vaccine caused profound improvement, and they seemed to precipitate the formation of localising abscesses in the red patches which appeared at the onset of the illness. As the antihæmolysin titre of the serum increased only from 75 to 250 units it is doubtful whether any improvement can be attributed to the antihæmolysin. (It may be recalled that Todd⁴ in his work on the infection of mice by hæmolytic streptococcus found that no protection against infection was obtained by the use of antitoxin nor by the use of high-titred antihæmolysin; in all probability the improvement in some of the mice was due to a protective antibody at present unknown.) The possibility of complement cannot be neglected, for it has been found by Cadham⁵ that in acute infection the complement titre may be low during the acute phase of the disease. The introduction of complement by the way of whole blood from a healthy person may in this case have done much to combat the infecting organism.

GROOVED ALUMINIUM VERSUS WOODEN SPLINTS

By A. P. BERTWISTLE, F.R.C.S. Edin.

THE materials used for splints by doctors in their own surgeries are amazing; I have seen folded newspaper, cardboard, and rough pieces of boxwood employed. Many hospitals use wooden splints, some fashioned, others not. The St. John Ambulance

FIG. 1.—Jones's cock-up splint.

Brigade use straight wooden splints. I believe that if the advantages of grooved aluminium were more generally realised this would be the material of choice. Aluminium splints may be divided into two classes:—

1. *Emergency, home-made.*—Sheet aluminium, gauge 22, will be found to be the best, for it is sufficiently strong and yet is easily cut with tinsmith's shears, which are like massive scissors and readily procured. The requisite length is cut, sharp corners are removed, and the splint is guttered by hammering over a rounded object or even by hand. This guttering is imperative, since without it aluminium will bend under a slight strain. Half-inch adhesive plaster is fastened round the edges; this serves

to do away with rough edges and helps to steady the subsequent padding. Such splints are invaluable for special fractures—e.g., in small children. A stock should always be available.

2. *Rolled.*—These are greatly to be preferred, since the even rolling makes for increased strength. The tinsmith rolls them in his rollers so that the gutter forms an arc of a circle with a radius of 2 in., more or less; more in the case of splints of more than 2½ in. across and much less in the case of finger splints. The edges are covered with adhesive as before.

The following are the advantages claimed. (1) *Strength.* Experimentally a rolled tinsmith's splint 9 in. long by 2½ in. wide, of 22 gauge, suitable for

FIG. 2.—Forearm splint.

a forearm, supported at each end, withstood a weight of 112 lb. placed on its middle. Such strength is quite sufficient to cope with most of the stresses and strains to which the splint would be liable. An emergency splint broke down under half the weight. (2) *Economy.* The fashioned wooden splint—and no other wooden splint should be permitted—costs considerably more than the aluminium one. The Robert Jones cock-up splint, which is readily made by cutting out a section to accommodate the thenar eminence and turning the end backwards, costs much less than Carr's splint for Colles's fracture. (Incidentally, surely the dorsiflexed position is the proper one for Colles's fracture? The fragments showing little tendency to movement, the wrist is much stronger in that position than palmar-flexed, and the fingers can be freely moved.)

FIG. 3.—Splint for great toe.

(3) *Lightness and small bulk.* The aluminium splint has the double advantage of being more comfortable to the patient and of being easily stored. The two splints used for Colles's fracture weigh 6 oz., whereas two aluminium ones weigh 2 oz. and are stored in a fraction of the space, unpadded. (A few placed under the seat of a motor-car may on occasion be invaluable.) (4) *Asepsis.* Open fractures and those associated with wounds are liable to soil the splint, which should be discarded. Aluminium ones may be boiled. (5) *Radiolucency.* A fracture may be radiographed with the splint in situ.

Aluminium splints are ideal for fracture of the radius and ulna, the commonest bones to suffer. They are excellent for fractures of the digits, often allowing the patient to continue his work, as a clerk for example. In the case of the toes, especially the great one, the splint has to have a sole, and in practice needs changing weekly because it is liable to break if weight is borne. Aluminium splints may be used for fracture of the fibula, and are invaluable in the first-aid treatment of fractures of the tibia and fibula in children and adults and of the femur in children. In these days of motor accidents and X ray plants too little attention is paid to the all-important first-aid treatment of fractures.

ROYAL SOCIETY OF ARTS.—On Feb. 10th, 17th, and 24th Major-General Sir Robert McCarrison, late director of nutrition research, Indian Medical Research Fund Association, will give three Cantor lectures to the society (John-street, London, W.C.) at 8 p.m. He will speak on Nutrition and National Health.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF ORTHOPÆDICS

At a meeting of this section on Jan. 7th, with Mr. ALAN TODD in the chair, methods of treating

Club Feet and Pes Cavus

were illustrated by cinematograph films and by patients showing successful results. The first film, exhibited by Mr. DENIS BROWNE, detailed his method of treating congenital talipes in infants. He felt convinced that one class of deformity was due to mechanical intra-uterine forces. The most important from the point of view of the child's future was talipes equino-varus, which, he believed, was a moulding deformity due to pressure of the uterus on the outer side of the foot; the responsible single factor was the position of the foot in the uterus; a normal right foot took the pressure of the uterine wall on its sole. The essential part of the deformity was a twisting inwards of the fore part of the foot, which was forced round into the reverse position. In these cases there was also a thinning of the skin over the convexity of the foot. It was very important to treat this deformity in infancy, while the bones were soft and the tissues supple. After forcible manipulation to bring the foot beyond the normal position, the ankle was dorsiflexed and kept in position with strapping, and both feet were bandaged to one rigid foot-piece. This treatment restored muscle balance, and the vigorous kicking indulged in by the child showed the muscles to be in good working order; indeed this kicking was a very important factor in the treatment. A later stage was depicted with the splint removed and the foot in a normal position, with no tendency to revert to the abnormal. As soon as the child was able to walk it was made to stand up in the splints, and twice daily the foot was strongly dorsiflexed.

Mr. B. WHITCHURCH HOWELL congratulated Mr. Browne on his results, which represented a great advance in the treatment of club-foot. There was likely to be a difficulty if the method was carried out as a routine in outlying country districts, where after-care might be inadequate.

Mr. NAUGHTON DUNN (Birmingham) remarked that the series of results shown by Mr. Browne were extraordinarily good. This method of maintaining external rotation was the best he had seen, and, as it was simple, he considered it was more applicable to treatment in country places than other current methods. He stressed the importance of counterbalancing the corrective forces by equal pressure on the outer side of the neck of the bone, because, unless the operator exercised care in this respect, a rotation of the astragalus on the ankle-joint would obliterate the hollow in front of the external malleolus. The presence of this indicated true correction but in its absence a relapse was almost sure to follow. Another important point was that over-correction of the club-foot deformity might result in severe valgus deformity. It was essential first to secure over-correction and then a restoration of the muscle balance. It was a great advantage if, as Mr. Browne had said, it was unnecessary to elongate the tendo Achillis, but in some patients he himself had not found that the case. If the tendon was not fully stretched, the patient would be liable to have a permanent flat-foot. The surgeon must not maintain

over-correction too long, and he must be sure that the tendo Achillis was long enough to allow dorsiflexion in the position of inversion.

Mr. DENIS BROWNE replied that cutting the tendo Achillis was, in his opinion, a crippling and deforming procedure.

The CHAIRMAN demonstrated by means of a film his operation for the treatment of pes cavus, the results of which were shown to be excellent. He explained that, although he worked at and evolved the procedure independently, he did not claim for it any originality.

Clinical Cases

Mr. C. LAMBRINUDI showed two lantern slides of a case of osteochondritis of the outer condyle of the femur. The patient, a woman aged 70 years, had fallen down and hurt the inside of her knee. Shortly afterwards a swelling appeared there which remained localised, and she had since suffered a good deal of pain. She had sought advice at several places, but not until the exhibitor saw her was a skiagram taken. Both flexion and extension were preserved, and no extra heat could be detected in the part. She was definitely better after a short time in bed.

After describing the good result from fascial repair of a torn ligamentum patellæ in a boy aged 17, Mr. ROOYN JONES showed a case for diagnosis. The patient, a man aged 57, and seen that day for the first time, occupied himself in slaughtering diseased animals. Some weeks before, following a scratch, his finger had become swollen and the swelling had persisted and increased. It was not tender, but the tendon sheath felt boggy; movement of the metacarpo-phalangeal joint was limited. The bone did not show any suggestion of a pathological condition.

Mr. V. H. ELLIS suggested that the condition was a tuberculous infection, which was common among those engaged in animal slaughter. It was probably a tuberculous teno-synovitis and should be immobilised in plaster for a time to see what happened.

The CHAIRMAN did not regard the condition as tuberculous, but probably an anaerobic infection of low virulence. He suggested puncture, and an attempt to cultivate the material obtained on both anaerobic and aerobic media.

Mr. C. HOPE CARLTON also thought it was not tuberculous but he would hesitate to puncture it. That kind of low-grade infection in the fingers was not uncommonly seen in industrial areas, and the outlook, he thought, was bad. Some form of high temperature treatment and radiant heat could be tried, but even then the prospect of retaining the finger was poor.

Mr. DUNN said he was not sure whether this was a tuberculous condition or a low-grade infection, but he had treated a similar condition in a butcher. The sheath was exposed and there was a general synovial thickening, which was removed surgically, and the result was good. It would be a waste of time to immobilise a finger in a man who was eager to resume work; amputation would be best in the case of recurrence.

Mr. E. P. BROCKMAN also showed as a case for diagnosis a man, aged 60, who in 1929 had complained of pain in the hip-joint, and, a year later, arthritis was present in the joint. He did a Rickman's reconstruction and found only osteo-arthritis with some pedunculated folds in the synovial

membrane. The man said that in 1915 he had had a cyst removed from the hip-joint. No tubercle had been found. Last year the man could not walk so well, his pain had become greater and at length persistent, and a lump was noticed. Bearing in mind the man's age and the absence of remissions in the pain, he thought it was likely to be a case of sarcoma.

Mr. DUNN diagnosed an ossifying chondroma, the pain being probably due to a stretching of the sciatic nerve over the bone. The best treatment was to expose the area and remove the tumour for pathological investigation.

ROYAL ACADEMY OF MEDICINE IN IRELAND

At a recent meeting of the section of surgery, with the president, Mr. SETON PRINGLE, in the chair, Mr. A. B. CLERY read a paper on the

Enucleation of Pleural Adhesions by Open Operation

This operation, he said, was particularly indicated in patients with one or two apical adhesions extending into the region of the subclavian vessels. The skin incision was as for an upper thoracoplasty, the deeper muscles being divided in the line of the third rib. Having retracted the scapula, 2½ to 3 inches of the rib were resected, and the pleura opened by diathermy. Light-bearing retractors were introduced into the pleural cavity and the adhesions enucleated from their attachment to the parietal pleura by the diathermy needle under direct vision.

Dr. G. T. O'BRIEN described the clinical course of three patients upon whom this operation had been carried out. In two of them the sputum, previously

T.B. positive, was negative within a fortnight of the operation, and cavities had closed in six weeks. In the third case laterally directed adhesions were enucleated, but infiltration of tissue by tubercles about the subclavian vessels prevented the lung apex from being freed. The cavity in this case had diminished in size. Treatment by artificial pneumothorax had been continued in all three cases.

Mr. F. J. HENRY thought there was scope for preliminary thoracoscopy in these cases, as some of the adhesions might be suitable for closed division. He drew attention to the necessity for air-tight closure of the wound, or the pneumothorax might become incompetent by leakage, the lung re-expand, and the adhesion become reattached. To prevent this, it might be well to suture the cuff of enucleated pleura over the raw stump of the adhesion.

Mr. T. A. BOUCHIER-HAYES referred to two cases he had treated in a similar manner, one of which, in whom the third and fourth ribs were resected, developed surgical emphysema:

Dr. J. B. MAGENNIS, while agreeing that the method afforded a new way of dealing with adhesions which could not be dealt with by thoracoscopy, thought it would be wise to do a preliminary thoracoscopy. There was, he felt, a definite danger of surgical emphysema.

Mr. CLERY, in reply, said he did not decry the value of thoracoscopy; he wanted to show that the open operation could be done if necessary. Surgical emphysema, he thought, would not be a serious complication.

Dr. R. STUMPF read a communication on a new method of low-voltage X ray therapy for easily accessible cancers, known as Chaoul's contact treatment. Of 35 cases in which the treatment was completed, 25 cases were clinically healed.

REVIEWS AND NOTICES OF BOOKS

Body Water—the Exchange of Fluids in Man

By JOHN P. PETERS, M.D., Professor of Internal Medicine, Yale University School of Medicine. London: Baillière, Tindall and Cox. 1935. Pp. 405. 18s.

WATER is so close to the roots of life that there is no branch of medical or physiological research where the investigator does not sooner or later encounter problems involving some insight into fluid metabolism. While it seems that certain aspects of the subject, such as the impermeability of the cell membrane to the potassium ion, are likely to remain inscrutable as long as life remains undefined, a great deal of useful information has accumulated about less obscure questions. Anyone who attempted to survey comprehensively the spate of papers on water metabolism which flows in ever-swelling volume through the channels of the biological press could only produce the type of review which exacts the epithet "monumental," and, being essentially lifeless, earns it. Interminable catalogues of conflicting conclusions and opinions, punctuated by strings of surnames in unlovely juxtaposition, and unleavened by critical comment, dismay rather than help the reader. Prof. Peters has avoided this danger and has somehow succeeded in weaving the 900 odd items of his bibliography into an intelligible argument.

He has concerned himself in the earlier chapters with the transfers of fluid which are continually

occurring between the various compartments of the body: from blood-vessel to interstitial space, to serous or joint cavity, to subarachnoid space; from interstitial space to lymphatic, from plasma to corpuscles, and so on. He attempts to explain these movements in terms of certain physical and physiological postulates, like the Donnan theory of membrane equilibrium and the Starling theory of the formation of interstitial fluid. It is a difficult task, for hydrostatic principles and collodion membranes are simple compared with hydrodynamics and membranes of varying permeability, but Prof. Peters handles his bulky data well. One or two minor points call for criticism. There is a school which clings to the odd belief that the intercellular spaces are filled with a protein gel, a sort of sponge which soaks up or exudes fluid in response to changes in hydrogen-ion concentration. In recoiling from this untenable hypothesis the author goes too far and implies that the immediate environment of the cell is wholly saline and circulating. But something tangible must also be present to maintain the architectural integrity of tissue, and whether that something is the mucinous ground substance of the older histologists, or the reticulum of more modern writers, there is certainly a fixed, as well as a circulating component in the environment of the cell, and the physiologist will sooner or later have to take it into consideration. Again, in discussing synovial fluid Prof. Peters finds great difficulty in accounting for the presence of mucoprotein. He is evidently not

alone in this difficulty, for he quotes attempts which have been made (of course unsuccessfully) to discover mucous secreting glands in synovial tissue. Surely it is well enough established that mucoprotein is a normal constituent of most tissues.

In a later chapter Prof. Peters considers the various ways by which the body gains or loses water, an important subject if only in view of recent attempts to make the measurement of water exchange a practical clinical proposition. The technical difficulties and possible sources of error in what to the uninitiated may appear a simple procedure are discussed at some length, and the reader is left with the feeling that for ordinary purposes measurement of fluid intake, urine output, and body-weight, however unscientific, remains at present the only practicable way of deciding whether a patient is gaining or losing water. The latter, and perhaps the more valuable half of the book, is devoted to a consideration of the physiology of the secretion of urine, and forms an up-to-date and readable review of this most difficult subject.

Prof. Peters's book is not likely to appeal to the general reader, but the physiologist or clinician whose researches have brought him unexpectedly to the shore of fluid metabolism would be well advised to consult it. It should at any rate save him from drowning in a sea of irrelevant references.

Aids to Medicine

Fifth edition. By JAMES L. LIVINGSTONE, Physician to King's College Hospital; Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Brompton. London: Baillière, Tindall and Cox. 1935. Pp. 422. 5s.

AN eastern potentate commanded his wise men to write the history of his people, but rejected their work because it was too long; they abridged it again and again, and finally satisfied him on his death-bed with the version, "They lived; they suffered; they died." Medicine has not yet been compressed quite so far, but in Dr. Livingstone's "Aids" it is reduced to remarkably small compass. The fifth edition has been brought up to date, and is based, as may be inferred from the preface, on Price's textbook and Tidy's Synopsis. The summarising is well done, and the text is clear, easily read, and quickly grasped; if the student needs to swallow his medicine in pill form just before his examination this is no doubt an excellent pill—perhaps the best, with one notable exception, and that is a summary made by the student himself. To condemn the "aids" altogether is admittedly a counsel of perfection, but it is to be hoped that many of our students are intelligent enough, well enough taught, and wisely enough examined to be able to dispense with them.

Early Diagnosis of the Acute Abdomen

Seventh edition. By ZACHARY COPE, B.A., M.D., M.S. Lond., F.R.C.S. Eng., Surgeon to St. Mary's Hospital, Paddington; Senior Surgeon to the Bolingbroke Hospital. London: Humphrey Milford, Oxford University Press. 1935. Pp. 254. 10s. 6d.

THIS book is already well known. Changing conditions have called for alterations in the text, and it is likely that in time further modifications will be required, especially in the chapters dealing with intestinal obstruction. It is questionable, for instance, whether the statistics from St. Mary's Hospital, showing that out of 300 cases of acute obstruction 177 were cases of strangulated hernia, give a true

picture of the present incidence of strangulation now that radical operations for hernia are more frequently performed before the onset of complications. It is also to be noted that in this book, which is distinguished by the clearness and soundness of most of its teaching, the account of intussusception should be rather unconvincing and out of harmony with present day views on this condition. Mr. Cope's work records the fruits of careful clinical study, and herein lies its excellence. The introduction of more elaborate methods of examination seems rather to detract from its value. For example, it is doubtful whether it is sound to regard the use of radiography as an advance in the early diagnosis of intestinal obstruction, and it is surely a mistake to suggest that cystoscopy should be undertaken to diagnose rupture of the bladder. Insufficient stress is laid upon the value of auscultation in the investigation of cases of acute intestinal obstruction, and more detailed consideration might well have been given to rupture of the spleen. These criticisms on matters of detail are made in the confident belief that many further editions of this valuable monograph will be called for.

Healing: Pagan and Christian

By GEORGE GORDON DAWSON, M.A., B.D. Camb. London: Society for Promoting Christian Knowledge. 1935. Pp. 322. 9s.

IN this book the author attempts to consider in a comprehensive manner the principles of therapeutics; he finds the restoration of health to occur through the three avenues of the body, mind, and spirit, and labels the usual treatment of the sick as departmental. It follows that arguments are set out for religious healing as distinct from therapeutic treatment, and for coöperation between the pastor and the physician in effecting cures. The first part of the book surveys the very earliest conceptions of disease and death, reviewing the art of healing as displayed by the ancient civilisations and by primitive doctors. This brings us along a well-worn track through the medicine of the Greeks and Romans to the Christian era, so leading to the chapters dealing with the methods of healing associated with the Christian Church. Here proper stress is laid upon the value of monkish learning, and although there is not much to be said in this connexion which is not familiar to those who are at all well read, the material is set out in an easily assimilable form for the uninformed. But presumably the book was written largely to promote the views, as expressed in the closing sections, on mental and spiritual healing, and because these views are clearly set out we recommend them to attention. The medical profession is more ready to listen sympathetically to evidence pointing to the value of religious healing than the church appears to know.

Félix Lejars: Traité de Chirurgie D'urgence

Ninth edition. By PIERRE BROcq, Professeur agrégé à la Faculté de Médecine de Paris; Chirurgien des Hôpitaux. Assisted by ROBERT CHABRUT, Ancien Chef de Clinique à la Faculté de Médecine de Paris. In two volumes. Paris: Masson et Cie. 1936. Pp. 1299. Fr.200.

THE last edition of this book appeared in 1921. It was popular because of the simple and clear way in which every problem was tackled and explained, and because the recommendations were so obviously the fruit of the experience of a master surgeon. The

scope is a little different from that of any treatise on emergency surgery we have available in this country. It is more comprehensive, including many affections which are not immediately urgent in the strict sense of the word, and is the more valuable for its wider appeal. The book is addressed to the practitioner as well as to the young hospital surgeon. Emergency operations in every branch of surgery including the female genital organs, the ear, the eye, and the nose are described. The use of the œsophago-scope is recommended though its technique is not given; neither for that matter is that of the cystoscope and the urethro-scope. These methods are evidently considered too specialised for those to whom the book is primarily addressed. But it is not only practitioners and junior surgeons who will find it useful. It should be on the shelves of every operating surgeon, and easily accessible, for precise instructions are given for the treatment of emergencies seldom encountered apart from war, such as stab wounds involving the large vessels at the root of the neck, and rare emergencies, such as strangulated obturator and sciatic herniæ. The new authors have carried out an extensive revision of the work, have added much new matter, and have succeeded admirably in preserving its attractive character.

The Nelson Loose-Leaf Living Surgery

Renewal pages. Vol. III. *Orthopædic Surgery*. New York: Thomas Nelson and Sons. 1935. Pp. 179.

THE most recent renewal pages to reach us of this composite surgery are really the first instalment of a revised and enlarged section on orthopædic surgery. The death of the former author, Nathaniel Allison, has necessitated the appointment of a new editor, R. K. Ghormley, who has called to his aid a number of experts in the different branches of orthopædic surgery. This gives a very individual character to the subsections, and the teaching in some places differs materially from that of British surgeons. Thus the only treatment of spinal caries seriously considered is a bone-fusing operation; in the treatment of congenital torticollis division of the upper end of the sternomastoid is recommended, whilst the contraction of the cervical fascia and scalenus anticus as component factors is ignored. Such deviations from current practice in this country, however, make the volume the more valuable to British surgeons. There is an attractive chapter on malacic disease of bone and another on degenerative diseases of the spine, where the pathology of the intervertebral discs receives due notice. The growing feeling against violent measures in the correction of congenital talipes equino-varus is well expressed in an informative article. These examples are mentioned to show that the work is being kept well abreast of current thought, and the publishers and editors must once more be congratulated on maintaining the high ideal of service envisaged at the inception of this novel system of text-book construction.

British Journal of Children's Diseases

IN the October-December issue (vol. xxxii.) Dr. E. Ashworth Underwood concludes his article on the Neurological Complications of Varicella with a general discussion on pathogenesis. A bibliography of 186 references is appended together with a list of 120 cases collected from the literature from 1873 to 1935, including an original case of cerebellar ataxia in a girl of 8.—In the concluding part of his Analysis of over Four Thousand Cases of Educational

Deafness Studied during the Past Twenty-five Years, Mr. Macleod Yearsley maintains that the education of the deaf must be based not on the considerations of different systems but on the study of the deaf child as an individual. According to his scheme of classification, which is based on school medical inspection, deaf children fall into four groups: the slightly deaf, the semi-deaf, the very deaf, and the defective deaf, without there being an absolute line of demarcation between the groups. He is opposed to residential deaf schools, except where they are necessary to serve large areas without day deaf schools, and is pessimistic as regards the general condition of deaf education in this country and its future prospects. He recommends that fresh legislation of a wide nature should be started without delay by an Act which would embody the necessity for early detection of deafness, education of the deaf from pre-school to post-school age, and training and employment.—Dr. J. W. Healy contributes a paper on Diabetes Insipidus as a Manifestation of General Miliary Tuberculosis. The patient was a male child aged 2½ years in whom the cause of death was acute external hydrocephalus and acute tuberculous meningo-encephalitis, the terminal phenomenon of a tuberculous infection of much longer duration. An intercurrent attack of diphtheria was a subsidiary contributing factor. The fact that diabetes insipidus appeared before other symptoms and that pituitary diseases had progressed to a greater extent than the tuberculous lesions elsewhere suggested that the onset of the syndrome corresponded with the commencement of tuberculous infiltration of the pituitary.—The abstracts from current literature are devoted to nervous and mental diseases.

NEW INVENTIONS

A TUBE FOR CONTINUOUS GASTRIC ASPIRATION

CONTINUOUS aspiration of the stomach is a valuable form of therapeutics in such conditions as intestinal obstruction, acute dilatation of the stomach, vomiting after gastric operations, and persistent vomiting of pregnancy. When the tube is introduced by way of the nasal route it can be left in situ for many hours. The patient can drink as he pleases and this, as well as satisfying his thirst, helps to wash out his stomach. If one nostril and the back of the throat are cocainised the tube can be introduced almost without discomfort. The tube

illustrated is designed for this purpose. The spring within its terminal portion so stiffens it that the nose can be catheterised easily. The end of the tube is seen at the back of the pharynx, where it is grasped by a long hæmostat, which is used to milk the tube down the œsophagus.

The tube is made by the Genito-Urinary Manufacturing Co., Ltd., and is supplied in two sizes.

HAMILTON BAILEY, F.R.C.S. Eng.

THE LANCET

LONDON: SATURDAY, JANUARY 18, 1936

A FORWARD MOVE IN EDUCATION

THE history of the school medical service is one of gradual expansion from the routine inspection of children at certain set periods of their school life to a fairly comprehensive system of care and treatment in clinics, hospitals, and special schools. Its development was noticeably rapid in the early years after the war, but the depression of recent years has caused some retardation in the rate of advance. In spite of the vigorous support which nursery schools have received, especially from women's organisations, remarkably little provision of this kind has been made, and some of the other special services are only a little less inadequate in many areas. The Board of Education now lays stress upon the need for a forward policy on the part of local authorities,¹ and as these are still grant-earning services, unaffected by the introduction of a block grant by the Local Government Act, 1929, it is likely that those authorities whose finances are not crippled by the burden of public assistance will respond. Attention is drawn to the fact that the dental service is seriously incomplete in most parts of the country. In order to afford sufficient dental care it is estimated that one dentist is required for every 5000 urban, or 4000 rural, children. School dentists fall notoriously short of this number, and many children cannot receive attention without prolonged and harmful delay. At the same time it must be remembered that this service has hardly touched the fundamental problem of the prevention of dental caries. There is urgent need for confirmation and extension of the work of Mrs. MELLANBY and others on the relation between dietary and caries. Part of the expansion of school dentistry might be avoided if we were sure of our facts and were therefore able to devote more energy to the education of mothers and children in the prophylaxis of dental decay. Unfortunately we are not yet in a position to put simple and incontrovertible information on the subject before the public, and until agreement has been reached among research workers we must depend upon conservative dentistry to ensure that the children leave school with healthy mouths, at least, if not with perfect teeth.

It is disconcerting to learn that the children under 70 authorities are still without provision for the prevention and correction of crippling defects. This is a straightforward problem, and, although the cost of such schemes per case may be high, the actual number of cases in any area is

comparatively small. Institutions and skilled personnel are available so that local difficulties should be easily surmounted. As to acute rheumatism, the grave cardiac sequelæ of which are emphasised in the Board's circular, there may be some difference of opinion about the most suitable type of provision. The modern treatment of early carditis requires practically the same sort of immobilisation as is practised in diphtheria, and this can rarely be obtained except in hospital. Fortunately the number of patients at any one time is not great, but they are better isolated from children suffering from other diseases, subjected to a reasonable open-air régime and mentally employed as in open-air schools. Wards set apart in general or fever hospitals may serve the purpose, but there is much to be said for quite separate institutions with attractive grounds. These institutions are still small, and experience shows that they need not be costly to run. Day and residential schools, both for the physically defective and the mentally subnormal, have not been developed to the extent which their established value might have led us to expect. A forward policy is now recommended by the Board. It is perhaps significant that no mention is made of special classes in ordinary schools for mentally subnormal children. This type of provision has been advocated, for rural areas at least, but it would appear that the Board's advisers prefer residential schools, if necessary under joint management. We should like to be sure that special classes have proved a failure before the more expensive alternative is adopted for every type of mentally subnormal child. In contrast, it appears to be left largely to local discretion whether children under 5 years of age, for whom authorities are now urged to make accommodation, should be received into specially constructed nursery schools or into modified parts of existing schools. When it is remembered that health, cleanliness, nourishment, and character training are the first requisites for these young children, and that few existing schools are capable of being suitably modified for the purpose, the case for ad-hoc schools seems overwhelming. Other recommendations of the Board, for instance, that special classes in ordinary schools should be provided for the partially sighted and the hard of hearing, and that the curriculum should be reorganised on the lines of the Hadow report, and, above all, the prospective raising of the school age, will place sufficient strain on the existing schools and their capacity for structural modification. A circular which is promised on the subject of physical education may make still further demands on both the internal and playground space of schools, so that it may be found more practicable to provide such facilities as those required for the younger group of children in totally separate buildings.

Education authorities are faced with a very complicated problem. School buildings are costly. Rightly or wrongly, they are solidly built to last for many years. Changing ideas in education tend to make their planning obsolete while their structure is still sound. The child population is declining,

¹ Board of Education: Circular 1444, Jan. 6th, 1936. H.M. Stationery Office. 2d.

and will soon fall rapidly, so that an inclination to avoid new construction for new types of provision is natural. Many schools, however, are unhygienic and cannot be modernised. While the prospective fall in the demand for accommodation must be kept in mind, it should not be allowed to influence too much the policy of local authorities in regard to the new or better types of service they are now being encouraged to give.

DILATATION OF THE URETERS IN PREGNANCY

It has long been known that the ureters and renal pelves tend to dilate during pregnancy, and this tendency is clearly of fundamental importance in the aetiology of pregnancy pyelitis. An obvious anatomical cause of the dilatation is the pressure of the gravid uterus on the ureters as they cross the pelvic brim, and for many years such pressure was held to explain the changes found. But the newer knowledge gained by modern urological methods has led to the suggestion that it is due to an atony of the ureters caused by some chemical substance circulating in the blood stream.

Dr. DUGALD BAIRD, of Glasgow, has made an extensive study of the changes in the upper urinary tract during pregnancy and the puerperium, and the results of six years' careful clinical research are at present being published.¹ He has approached the problem from both the anatomical and the functional side, for he has examined much post-mortem material and made many investigations on the living subject not only by intravenous pyelography and chromocystoscopy but also with an ingenious apparatus for measuring the tone of the ureteric musculature. His results, and also those obtained at the Johns Hopkins University,² demonstrate two factors in the dilatation of the ureters. That pressure by itself can bring about dilatation is shown by pyelograms taken in cases of pelvic cellulitis, ovarian cysts, and fibroids (though here it is never so advanced as during pregnancy); moreover, it is only anatomical differences that can account for the more frequent dilatation of the right ureter. Studies of the ureteric tone, however, show equally conclusively that during pregnancy the ureters become atonic: uterine pressure, when present, causes no compensatory hypertrophy or hypertonus; the ureter just stretches. Atony develops very early in gestation and is probably the cause of the early dilatation sometimes seen, though as a rule the pressure of the uterus on the atonic ureter is the deciding factor. One other possible cause also calls for consideration. At the lower end of the ureter there is a well-developed sheath of fibrous tissue and longitudinal muscle bundles, and it has been noticed that during pregnancy this sheath hypertrophies—so much so that the dilatation of the ureters has been ascribed to

hypertrophy of the muscle in the ureteric sheath, though the changes in the rest of the ureter are not those usually associated with obstruction at the outlet. The workers at Johns Hopkins University lay some stress on this hypertrophy, which they regard as hormonal in origin. They have found similar, though less conspicuous, changes throughout the urinary tract and suggest that oestrin, which is known to produce hypertrophy, oedema, and increased vascularity of the generative tract, might bring about similar changes in the urinary tract, since the two are derived from the same embryonic structures. The exact distribution of the epithelium which is specifically sensitive to oestrin is discussed by Dr. ZUCKERMAN in our present issue, with special reference to enlargement of the prostate.

The results reported by Mr. HAROLD BURROWS at the November meeting of the section of comparative medicine of the Royal Society of Medicine are all the more interesting in the light of this recent work. He has been studying the effects of the prolonged administration of oestrogenic substances to mice, and in addition to other remarkable phenomena already reported³ he has noticed that after several months the urinary tracts of the mice become grossly dilated and that purulent cystitis and pyelitis sometimes follow. LACASSAGNE⁴ and BURROWS originally ascribed these changes to urethral obstruction caused in the female by the keratin debris in the vagina, and in the male by the enlargement of the accessory genital glands. After further experiment on male mice, however, BURROWS now thinks they may be due to failure of the nervous or chemical control of the neuromuscular apparatus of urination; for he could find no definite urethral obstruction, despite the enlarged accessory glands and the keratinisation of the urethral mucous membrane. Those who were fortunate enough to see the specimens he demonstrated could not but be impressed by the large dilated ureters and the hydronephroses, and it is hard to resist the conclusion that there is some connexion between these findings and the ureteric dilatation seen in pregnancy, especially since it is known that large amounts of oestrogenic substances are excreted in the urine of pregnant women. On the other hand, the dilatation in mice was obtained only after administration of the oestrogens over periods far longer than the normal period of gestation in the mouse, and MENGERT⁵ has shown that the ureters of the cow, pig, macacus monkey, dog, cat, rabbit, guinea-pig, and rat do not dilate in pregnancy. BURROWS has demonstrated very clearly yet another property of the oestrogenic compounds, but in our present state of knowledge it would not be safe to draw general conclusions from effects observed in one animal.

Other experimental work, moreover, lends little support to the idea that oestrin is responsible for

ureteric dilatation in pregnant women. According to the current theory of the hormonal control of pregnancy, œstrin makes the uterus sensitive to the oxytocic principle of the posterior pituitary, increasing its tone, while the corpus luteum hormone (progesterin) renders it refractory and thus decreases its tone. In the first half of pregnancy the corpus luteum is dominant and the uterus is atonic; then the influence of progesterin gradually wanes while that of œstrin waxes and the uterine tone consequently increases. It is noteworthy that BAIRD finds a similar sequence in the human ureteric musculature, the tone of which also increases towards the end of pregnancy. In our own columns last year it was shown⁶ that during the greater part of pregnancy the œstrin excreted in the urine was mostly present in a "combined" form of low physiological potency, and that it becomes active only with the approach of full term. It seems reasonable to suppose that it is the presence of the active œstrin excreted with the approach of full term that makes the uterine muscle highly sensitive to pituitrin and so leads to the expulsion of the fœtus. According to these views it is the corpus luteum hormone (progesterin), and not œstrin, which one would expect to cause dilatation of the ureters; and, in fact, progesterin has generally been regarded as responsible for their atony during pregnancy.

THE GERSON DIET

It is now more than ten years since Dr. MAX GERSON, then a general practitioner in Westphalia, introduced a special salt-free diet for the treatment of tuberculosis and other chronic diseases affecting the general nutrition of the body. The origin of the treatment is of some interest, for it arose out of a personal experience. Fifteen years earlier, when GERSON was working in a hospital in Berlin, he made some experiments to see if a change in diet would cure the attacks of migraine from which he then suffered. Finding success from the elimination of salt, he tried the same thing on other people and was profoundly impressed by the results. It was the incidental recovery from lupus of a patient treated for migraine on this dietary that led to its trial in tuberculosis. The diet as modified by Dr. A. HERRMANNSDORFER, assistant to Prof. E. SAUERBRUCH, was extensively used in the treatment of patients with bone and joint tuberculosis at the Charité in Berlin. The essential feature of this modified diet was the large proportion of albumin and fat, with little carbohydrate and no common salt, the principal ingredients being unsalted butter, raw and cooked fruit, salad, steamed vegetables, meal and flour, eggs, pudding, unshelled rice, sugar, nectar, olive oil, and dripping. The Berlin Medical Society discussed the treatment in August, 1929,⁷ when the Giessen clinic reported success with lupus and it has since been tried at a number of sanatoria and special centres. But GERSON himself soon

came to feel that his followers were too willing to compromise with patients loth to renounce all the pleasures of the table at one swoop. The Gerson-Sauerbruch-Herrmannsdorfer diet may have been, and probably was, a model of culinary diplomacy, but GERSON himself scented heresy and would have none of it. What may have widened the breach between the two was GERSON'S growing conviction that his diet, modified to meet individual needs, was capable of curing an increasingly wide range of diseases from rheumatoid arthritis to gastric ulcer.

The true gospel of the Gerson diet is set out by its originator in a monograph of more than 600 pages, most of which, despite the title,⁸ deal with the diet and its modifications. The author believes that his diet will induce healing of pulmonary tuberculosis even in advanced cases provided that sufficient functioning lung tissue remains, that the patient's general condition is not too bad for him to take the diet, and that complications such as lardaceous disease are not present. But he insists that success depends on scrupulous observance of details which require nearly a hundred pages of close type to set out, although the scheme of the whole course is given on a single page (305) of the book. In Germany or Austria the cost of the diet is not much above that of an ordinary sanatorium menu; Dr. GERSON does not give the actual figures; presumably the cost must vary with the prices of the constituents in different areas. More than half the book is devoted to protocols of 25 cases, treated at the diet station of the Urban Hospital in Berlin under the direction of Prof. HERMANN ZONDEK, and of 26 cases treated later by the author in Austria. These protocols include radiograms, blood counts, and other details of progress, which can be assessed for what they are worth by those who have experience of such cases elsewhere. GERSON himself briefly summarises the story of the earlier series which with one exception belonged to the working classes, some of them being unemployed. In about half there was some family disposition to tubercle and of these all except one had some complication which made a favourable issue less probable. Two-thirds of the patients were between 18 and 35 years of age. They were under GERSON'S personal care for a period of only three to eleven months and he admits with regret that he was prevented from seeing the treatment through to the end; but of 19 whose treatment went on for another two or three months after he left the diet station he had news, although he expresses a doubt whether the treatment was carried on after his departure as correctly as it was when he was there. But he warmly thanks the nurses and cooks of the Urban centre for their untiring help in carrying out the treatment which had met with less difficulty there than elsewhere; two or three of the patients received constant attention both by day and by night. In no case did they find the diet irksome at the outset, but later three of

⁶ Cohen, S. L., Marrian, G. F., and Watson, M.: THE LANCET, 1935, i., 674. ⁷ See THE LANCET, 1929, ii., 404.

⁸ Diättherapie der Lungentuberkulose. Leipzig and Vienna: Franz Deuticke. Pp. 619. M.36.

them refused suddenly to go on with it; in one or two cases there was wilful transgression and one patient succeeded in nullifying the treatment by getting relatives to smuggle food in. But 22 of the 25 went through the course without complaint, and although they were all suffering from advanced tuberculosis, of which the prognosis under ordinary conditions was bad, none of them died within the first year. GERSON submitted his X ray records to Dr. FELIX FLEISCHNER, radiologist in Vienna, who formed the independent opinion that 24 out of the 25 were on the way to complete recovery.

Unfortunately this remarkable experience did not secure GERSON'S tenancy of the diet centre and he was obliged to continue his work at an Austrian hospital where he collected what seemed to the outsider an odd assortment of morbid changes. Not the least interesting of the cases were patients suffering from advanced rheumatoid arthritis who had come to him on the recommendation of some sufferer to whom the diet had brought relief. But here again GERSON was unable to continue his régime long enough to carry con-

viction to his professional colleagues and his success must be taken rather as a tribute to his personal qualities than as an indication that the treatment can be carried out widely. It seems that many physicians who have prescribed the diet have found patients rebel against its austerity, not least members of GERSON'S own race; they simply will not play the game when put on any rigorous diet, but eat all sorts of things surreptitiously. This must make an almost insuperable obstacle to carrying out GERSON'S precepts in any hospital which can be called voluntary. There is another possible reason for GERSON'S success which cannot be repeated outside Central Europe. Many of the people with whom he was dealing may reasonably be expected to have been in the habit of eating much salt pork, salt fish, and similar viands; any diet which corrected this national predilection was bound to achieve a certain amount of success. That is one reason why we may watch with interest a continuance of the experiment in a Paris suburb where GERSON is now with the help of friends and grateful patients running a special clinic.

ANNOTATIONS

SURPLUS AND DEFICIT

THIS is addressed less to our readers than to their wives and families, and we ask that it should be referred to the proper quarters. The facts are these. Clothing of all sorts—new, nearly new, or frankly old—can be used to great advantage by the Ladies Guild of the Royal Medical Benevolent Fund. The Guild has a clothes room at the B.M.A. House in London, and at present sends out parcels twice a year to more than 350 families or individuals belonging to our profession but left in financial straits. In compiling these parcels great care is taken to make them really useful to the recipients, for often they are essential to self-respect and a minimum of comfort. Sometimes new garments are needed; for example, when the Guild sees to the requirements of a girl at boarding-school it makes sure that she shall have the same kind of outfit as her schoolfellows. Nevertheless money is only a small part of the need felt at the clothes room; and whatever is sent to it—from evening dresses to coal-scuttles—the sender may rest assured that it will be put to the best use by those in charge of the department. Of late years many have become increasingly aware of the claims of the unemployed, and the competition of such admirable organisations as the Personal Service League has in fact lessened the never-sufficient flow of clothing and gifts to the Guild. But often the discarded dresses and suits and undergarments of professional people are definitely more suitable for the dependants of doctors than for the unemployed in general; and if the situation of such recipients were better known many of us would probably be glad to pass on our clothes at a less advanced stage of degeneration. It is not only clothes that are wanted; curtains, bits of carpet, blankets, sheets, towels, toys—any of these things may make a big difference to old people who have known better times or young ones who have not. At this time of year, however, the first and foremost need is warmth,

and anyone who can produce a warm coat or an eiderdown or a boy's jersey could not do better than send it at once to the Ladies Guild of the R.M.B.F. at B.M.A. House, Tavistock-square, London, W.C.1.

CHRONIC GASTRITIS AND PERNICIOUS ANÆMIA

IN pernicious anæmia Castle's intrinsic factor is not produced by the patient's stomach, and there is a complete achlorhydria which usually persists indefinitely in spite of treatment. Fifty years ago Fenwick showed that the gastric mucosa, at least during a relapse, is atrophic, and the atrophy has since been regularly demonstrated by pathological and gastroscopic observations. Those are established facts, and they are commonly taken to mean that the gastric mucosa, congenitally defective or progressively damaged by gastritis, first loses its acid-secreting power and then its power of secreting intrinsic factor, at which stage pernicious anæmia appears secondary to the gastric defect, which is permanent and irreparable. This working hypothesis, however, has recently been somewhat shaken. Jones, Benedict, and Hampton,¹ from Harvard, describe 5 interesting cases of pernicious anæmia in which repeated gastroscopic examinations were made, and in 3 of the 5 were checked at operation by direct inspection and biopsy. They found atrophic changes in some cases, but hypertrophic changes in others, and what is more important, they have good evidence that these stomachs reverted strikingly towards normal when the pernicious anæmia remitted under treatment. If that is confirmed, it means that the structural changes in the gastric mucosa in pernicious anæmia are reversible, as the lingual changes in both pernicious anæmia and sprue are already known to be. If so, they can scarcely be a congenital defect, and are not easily explained as "inflammatory" in the classical pathological sense. The door is open for the suggestion that some sort of nutritive deficiency may determine them, and the suggestion is forthcoming, by analogy,

¹ Jones, C. M., Benedict, E. B., and Hampton, A. O.: *Amer. Jour. Med. Sci.*, November, 1935, p. 596.

from Miller and Rhoads,² who, by feeding swine on deficient diets, have caused acid and intrinsic factor to disappear from their gastric juice; they are not yet certain whether they have induced atrophic changes in the gastric mucosa at the same time. Whether it proves directly applicable to the pernicious anæmia problem or not, this work is of great value for directing attention to the influence of dietary factors on the structure and function of mucous membranes in general, a subject well worth further investigation.

A JOURNAL FOR THE PUBLIC DENTAL OFFICER

WE have received a copy of the first number of the *West Riding Dental Journal*, the first dental journal in this country to be issued expressly for the public dental officer. It is published by the dental staff of the West Riding County Council of Yorkshire with the laudable object of coördinating the medical and dental services in the riding. This issue opens with a series of excerpts from various reports which illustrate some of the salient features of school dentistry as well as the variation in methods adopted in different areas. A number of abstracts from current literature on the subject of school dentistry should prove helpful to the dental staff. Propaganda plays an essential part in securing the popularity of the school dental service and a committee of school dental officers in the West Riding has been considering this problem and their report is published here. We congratulate the West Riding authority on their enterprise.

THE MANIC-DEPRESSIVE AT LARGE

AT Tuesday's meeting of the Society for the Study of Inebriety an enlightening account of the inter-relationships between alcoholism, crime, and manic-depressive disorder was given by Dr. W. Norwood East, a commissioner of prisons. His paper appears in full on p. 161 of this issue. Dr. H. J. Norman, who followed him, expressed surprise that no one before Kraepelin should have given a really adequate description of the disorder. While the acute phase lasts there is no difficulty, even for the layman, in deciding that the person is insane, but at the beginning of a phase the question of diagnosis may not be at all easy; and when the phases are of brief duration, the symptoms may no longer be obvious when the individual comes under observation. Still greater is the difficulty when the morbid cycle is of the mild or cyclothymic type, in which eccentricities of conduct, even to a criminal extent, may occur, especially if self-control is still further impaired by alcoholic excess. The taking of alcohol to excess, often merely a symptom, is definitely so in some of these persons. As Clouston had pointed out, the morbid craving may be coincident with the period of depression, but far more commonly with the beginning of the periods of exaltation. Dr. Norman agrees with Dr. East that crimes of violence are committed much more frequently by the depressives; but it is the excited and exalted subjects who give the greatest amount of trouble by their mischievousness, malice, perversion of the truth, intractability, and destructiveness. For this reason those who have charge of manic-depressives often welcome, with a sigh of relief, the onset of the depressive phase. Dr. Norman admitted that the treatment of manic-depressive disorder is unsatisfactory. When its aetiology is discovered, it may be possible to devise efficient

therapeutic measures. Psychological treatment has not been successful. Dr. Norman said he was in full accord with Dr. East that imprisonment may be the only means of protecting the manic-depressive alcoholic from himself—if he does not become certifiably of unsound mind. But since anyone has the right to drink himself paralytic and poverty-stricken, the question of treatment becomes a forensic one. Some more effective means might, Dr. Norman thinks, be found to limit the right of the individual to do mischief to himself and to others—something, it may be, on the lines of the "family council" whereby a person is placed indeterminately under care and until such time as he can make his conduct approximate to that of the normal citizen. Clouston had insisted that the legislature must provide some remedy for this great evil to society and the intolerable hardship to relatives. "Something," Dr. Norman concluded, "might even have been made of Nero if, instead of being pandered to and given unlimited power, his liberty had been restricted and he had been compelled to obey for a longer period the wise counsels of Seneca and of Burrus. He might really have become a good violinist or a competent charioteer and thus fulfilled two of his ambitions instead of providing an example for incendiaries and multiple murderers."

PAIN FROM THE BILE-DUCTS

THAT biliary pain is sometimes due to dyskinesia of the muscle of the ampulla of Vater has been known for some time, and Dr. Charles Newman's Goulstonian lectures of 1933 made it clear that the two main types of disorder—the spastic and the atonic—are of everyday occurrence and everyday importance.¹ Hitherto the condition has been studied mainly by physicians and physiologists, and it is surprising that surgeons have not taken more interest in what is, after all, one of the common causes of symptoms persisting after cholecystectomy. The deficiency in surgical investigation has now been remedied, however, by Best and Hicken,² who have confirmed previous observations, and have demonstrated the spasm of the ampulla muscle after cholecystectomy by filling the bile-duct system with radio-opaque oil. The complete obstruction to the flow of bile and its purely spasmodic nature are well shown by the photographs they reproduce, and their work is a pretty demonstration of the rightness of conclusions drawn from the results of indirect investigation with the duodenal tube and from the beneficial effects of paralysing the muscle with atropine. There can now be no doubt that a purely functional spasm may lead to complete obstruction of the common bile-duct, and to considerable pain and digestive disturbance. One of the causes of this spasm is cholecystectomy, and it is the explanation of many instances of continued symptoms after operation. Best and Hicken also recognise, of course, that gall-stones and cholecystitis may reflexly cause such a spasm, but in their more surgical material have naturally taken less account of its origin in such conditions as duodenal ulcer, or of the commoner "primary" cases in which there is a more widespread state of vagal over-stimulation, attributable to "constitutional" causes. For the same reason they lay less emphasis than other writers on the value of sedative therapy with belladonna; but as a matter of fact it is remarkably successful in these

¹ Miller, D. K., and Rhoads, C. P.: *Jour. Clin. Invest.*, 1935, *iv.*, 153.

² Best, B. R., and Hicken, N. F.: *Surg., Gyn., and Obst.*, December, 1935, p. 721.

"surgical" cases. Insistence on the importance of functional, as well as organic, abnormalities has led to the relief of hitherto intractable symptoms arising from the extra-hepatic biliary system, and there must be other clinical problems in which it would be equally helpful.

A MENINGEAL FORM OF WEIL'S DISEASE

UNDER the name of "spirochétose méningée pure" French writers have been familiar since 1918 with a remarkable manifestation of human infection with *Leptospira icterohæmorrhagiæ* which seems to have escaped attention in this country and in Germany. It takes the form of a mild or moderate meningeal syndrome often accompanied by conjunctival suffusion, herpes labialis, and pyrexia.¹ The cerebro-spinal fluid shows only a slight increase in protein but a very large increase in cells, the majority of which are lymphocytes; counts up to 400 per c.mm. are on record. Jaundice may be present in this meningeal form of Weil's disease, but quite a number of cases are quoted in which there was no jaundice at all and in which conjunctival suffusion and a history of immersion in polluted water were the only pointers to the true nature of the disease. The cerebro-spinal fluid contains agglutinins for *L. icterohæmorrhagiæ* but their titre is much lower than in the blood. Guinea-pigs have been infected with blood and urine from pure meningeal cases. Where there is no jaundice or renal insufficiency the prognosis is highly favourable, and there appear to be no sequelæ. In view of the known existence of Weil's disease in this country among sewer-workers, canal-workers, coal-miners, and handlers of fish, the possibility of this meningeal form of the disease should be kept in mind, and it should not be necessary to wait for the appearance of jaundice before suspecting the possibility of leptospiral infection.

"CROCODILE TEARS"

IN 1905 H. K. Anderson² found that after excision of the ciliary ganglion the cut preganglionic fibres regenerated along the paths of the permanently destroyed postganglionic fibres and became functional. This was contrary to the accepted teaching of the time, which Anderson himself had helped to establish, that removal of autonomic ganglia was never followed by the least recovery. The probable explanation of the anomaly is now well known, and the laws of regeneration have been found to rest upon physiological rather than anatomical foundations. Transmission of nerve impulses across ganglia from preganglionic to postganglionic fibre is almost certainly achieved by the former liberating an acetylcholine-like substance which stimulates the latter and sets up new impulses. The preganglionic fibres are said to be "cholinergic." The postganglionic fibres, however, are of two kinds. Some of them stimulate the organs in which they end by liberating the same substance as do the preganglionic fibres, but others liberate an adrenaline-like substance. These last are said to be "adrenergic." The law of regeneration is that cut cholinergic fibres will, on regeneration, join up to old cholinergic end-points, but not to adrenergic end-points. Previous to Anderson's experiment, all ganglia which had been experimentally excised had had adrenergic postganglionic fibres, and these could not have been replaced by the cholinergic preganglionic

outgrowths. The ciliary ganglion, however, is now known to have cholinergic postganglionic efferents, and the manner of their replacement occasions no surprise (H. H. Dale³).

This theoretical background is implied in Mr. I. A. Tumarkin's interesting note (on p. 26 of our issue of Jan. 4th) on the syndrome of crocodile tears, when this occurs as a late sequel of Bell's palsy. He explains it on the ground of abnormal regeneration—"the nerve having undergone degeneration, new axons are pushing their way out seeking their various destinations. Unfortunately some are diverted, and find their way to the wrong muscle or gland." The same theory had been advanced⁴ by V. Uprus, J. B. Gaylor, and E. A. Carmichael to explain the recurrence of localised flushing and sweating after eating; they, as well as Mr. Tumarkin, drew attention to the fact that the best authenticated cases of crocodile tears followed a primary lesion in the region of the geniculate ganglion. The theory lacks actual proof, but the investigation carried out by the three authors named on a similar syndrome is extremely suggestive. The diagnostic importance of the theory is pointed out by Mr. Tumarkin, who gives details of the "fantastic course" pursued by the fibres causing lacrymal secretion. It is interesting to recall that this course was not always accepted, and that the general opinion was that the secretory nerves originated with the fibres of the fifth nerve. In 1902 Sir John Parsons published a review⁵ of the available anatomical, embryological, physiological, and pathological evidence on the point, and himself inclined to the view, now accepted, that they belonged to the seventh nerve. From the theoretical point of view, their important feature is that they are cholinergic. That other cholinergic fibres run in the seventh nerve is undoubted, for instance, vasodilator and secretory fibres to the submaxillary gland and various parts of the mouth, nose, and pharynx. If any of these, after section, grew down into the lacrymal gland, then an afferent stimulus giving rise (say) to salivary secretion would also cause lacrymation. There can be little doubt that this is what actually occurs.

ETHER CONVULSIONS

ONCE more that puzzling and dangerous complication, ether convulsions, has been the cause of a coroner's inquiry. On Dec. 31st at Camberwell, Dr. Douglas Cowburn inquired into the death of a woman, aged 53, who had been operated on for an abdominal growth. The convulsions began about an hour after the commencement of the operation, starting in the usual way with twitchings of the facial muscles. The ether used was proved to be pure, and in this and in other details the case does not differ from those previously described, though the age of the patient is rather above what is usual, and it is not reported that the patient had a septic focus or a high temperature—two features often observed. The convulsions are of course not always fatal, and many recoveries are on record. The last fatal case of which we have information occurred in London last summer, and it has been noted by Dr. Charles Hadfield that these fatalities are commoner in the warm months. This fits in with the latest theory of causation, put forward by Mr. Dickson Wright⁶—namely, that they are due to heat-stroke. He points out that in operating theatres to-day not only is the atmosphere kept warm but the patient, often

¹ Marie, J., and Gabriel, P., et al.: Bull. et mém. Soc. méd. Hôp. de Paris, Nov. 18th, 1935, p. 1454; Mollaret, P., et al.: Ibid., Dec. 9th.

already pyrexial, lies on a table heated by electricity or otherwise, and has probably had an injection of atropine which reduces heat-loss by abolishing secretion of sweat. Moreover, the ether vapour administered is often warmed. To those who share our disquiet about overheating and dehydration⁷ this theory is attractive; but it cannot be said to fit the facts of all recorded cases. Still less were these explained by the older suggestion that ether convulsions are due to impurities in the ether. This explanation indeed has been found untenable in almost every instance in which the ether has been carefully tested, although when it was first put forward by the late S. R. Wilson of Manchester there was much to support it. Some time ago the Anæsthetics Committee circulated a questionnaire to anæsthetists in many parts of the world in the hope of getting some light thrown on the causation of the convulsions; but the result was a complete disappointment. Continental anæsthetists seemed never to have witnessed convulsions under ether, and neither Canada nor the United States of America was able to provide an explanation more satisfactory than those put forward in Great Britain. Perhaps the oddest feature of the ether convulsion is its comparatively recent appearance. Ether was in use a number of years before 1912, when the first case was reported, and it is impossible to believe that the symptom could have escaped notice and description by anæsthetists of the vast experience and powers of observation possessed by Frederic Hewitt, Dudley Buxton, Walter Tyrrell, and others of that day. From the assumption that it was a new symptom came the suggestion that it arises from new methods of administration; yet this will not hold, for in some of the recorded cases the ether was given by the simple open-drop method. At present we must face the fact that ether convulsions, though still a rarity, are commoner than they were, and that their cause is unknown.

RELIEF OF ANGINAL PAIN

EFFORT angina, and the rarer spasmodic angina which comes on at rest but is not dependent on coronary occlusion or myocardial infarction, are nearly always readily relieved by the quickly acting vasodilator drugs. In fact, effort angina may immediately disappear if at the first warning the patient rests; while a tablet of nitroglycerin may enable effort to be made in comfort which would otherwise be impossible. On the other hand, carefully controlled observation on many drugs has shown that their continuous administration is of no benefit, and it is therefore surprising to read a report which claims for one of these not only the dramatic relief of paroxysmal cardiac pain but also its prevention when taken continuously. The drug is Aminophylline or Euphyllin, and Dr. J. F. Quigley⁸ describes its successful use for angina and also other forms of cardiac disturbances—though he makes no clear distinction between angina of effort, spasmodic angina, and myocardial infarction. The total amount of the drug used, in the form of tablets and injections, is stated, but not the total number of patients treated; notes on six cases (only four of which appear to have had some form of angina) are given, and it is admitted that the action in two of these was unfavourable. It is difficult to accept the view that a cardiac pain which does not respond to amyl nitrite will be relieved by a much less powerful vasodilator; yet this claim

arises from one of the successful cases, in which an agonising attack which had lasted an hour was completely relieved before the intravenous injection of 10 c.cm. of aminophyllin had been completed. Dr. Quigley gives some clinical criteria for the differentiation of "angina pectoris," by which is presumably meant effort angina, and "coronary disease," which may be taken to mean coronary occlusion or myocardial infarction. The description of the former as frequently unbearable is somewhat out of date; it would be better to say that it is usually mild; and to say no more of the treatment of myocardial infarction by morphia than that it may be of little help is rather an understatement of its value. The evidence so far available suggests that in the treatment of angina of effort (including spasmodic angina) there is nothing which nearly approaches the nitrites; and for most cases of myocardial infarction morphia is of the greatest use. Dr. Quigley's present report does not justify any modification of this generally accepted opinion.

SERUM TREATMENT OF STREPTOCOCCAL INFECTIONS

THE hæmolytic streptococci pathogenic for man comprise a number of diverse antigenic types. Their full number is as yet unknown, but they appear to be numerous, for F. Griffith¹ has already succeeded in identifying 27. These streptococci produce disease in virtue of two attributes, the ability to elaborate toxin and the power to invade the tissues. Some strains owe their pathogenicity almost exclusively to their ability to produce toxin—the scarlet fever strains, for example. Others depend largely, if not entirely, on invasiveness. Between these two extremes come strains whose pathogenicity is a product of both these factors. The truth of this is reflected in the results obtained in the treatment of streptococcal disease with antitoxic sera. If one excludes scarlet fever—in which condition streptococcal antitoxin has proved its efficacy—it has to be admitted that the use of this type of serum has given disappointing results. In some cases the results have been excellent, but in many others the serum has been without effect. To combat infections due to the invasive type of strain one must use an antibacterial serum, and unfortunately efficient sera of this type are not available. The polyvalent streptococcal antisera prepared in the past have not been a success; but when one remembers the great variety of antigenic types presented by the hæmolytic streptococci, and that a serum of the antibacterial type to be effective must possess type-specific antibody, this lack of success is not surprising. Whether the future will produce a satisfactory serum of this type it is too early to predict; at the moment the logical outcome of recent research would seem to indicate a polyvalent serum prepared against a very large collection of strains. In the meantime, however, we are not entirely powerless against this type of streptococcal infection. A note by Dr. Hendry and Dr. Griffiths, appearing elsewhere in this issue, describes a case which was successfully treated by immuno-transfusion. The patient, a woman infected with a highly invasive strain of streptococcus, received four injections of streptococcal antitoxin without material benefit. Her husband was then immunised with the strain which had been isolated and the patient was treated with whole blood from the immunised donor. Seven injections of 15 c.cm. were given, and on each

⁷ THE LANCET, 1933, i., 95.
⁸ Prescriber, 1935, xxix., 197.

¹ Griffith, F.: Jour. of Hyg., 1935, xxxiv., 542.

occasion they were followed by great improvement, the patient making a good recovery. Admittedly this is only one case, and Hendry and Griffiths consider that possibly the whole blood was effective in virtue of its complement content. In support of this contention is the report of good results which sometimes follow transfusion with blood from normal healthy donors. A recent paper by Stahl² gives his experience of this form of treatment. But work by Ward and Lyons³ in the United States has shown that the serum of healthy adults often contains antibody which is protective against one or more strains of hæmolytic streptococcus, so that simple transfusions may sometimes be providing the appropriate antibody as well as complement. This work suggested the possibility of using donors possessing the requisite antibody in the treatment of invasive streptococcal infections, and the procedure evolved, together with illustrative cases, is given in a paper by Lyons which has just been published.⁴ Briefly, his method consists in matching the donor against the streptococcus obtained from the patient. This is done by testing sera from a number of prospective donors by an in-vitro phagocytic test and selecting for donor the one whose serum produces the greatest degree of phagocytosis of the patient's streptococcus. And should the patient's clinical condition suggest that toxin is playing some part in the production of symptoms, then antitoxin is given as well. Lyons's work is still in its early stages and it will be interesting to see what sort of results he obtains with a more extended trial. But the method seems sound scientifically and well worthy of trial.

POLIOMYELITIS VACCINATION: A WARNING

Two forms of poliomyelitis vaccine are on trial in the United States.⁵ One of them, Kolmer's, is a living virus attenuated by treatment with sodium ricinoleate; the other, Brodie's, is a virus killed with formalin. At the annual meeting of the American Public Health Association last October⁶ it was agreed that Brodie's formalised vaccine is safe, though not necessarily efficacious. It had been given to 8000 persons, and though 1 of these had soon afterwards developed poliomyelitis there was reason to suppose the vaccine innocuous. On the other hand, of 12,000 persons receiving Kolmer's living attenuated virus as many as 9 had subsequently developed the disease; and, though Kolmer was convinced that all of them were already incubating the infection at the time of inoculation, his critics were by no means satisfied. Their doubts will be increased by a grave statement published in the *Journal of the American Medical Association* for Dec. 28th by Dr. J. P. Leake, medical director of the United States public health service. He summarises 12 cases, reported to the service, in which paralytic poliomyelitis has followed, at suggestive intervals, the injection of unnamed vaccines, A and B. Of the 9 having Vaccine A, 5 died; of the 3 having Vaccine B, 1 died: the ages of all but one were under ten years, and the deaths occurred 6-14 days after a first or second dose. Paralytic poliomyelitis was not endemic in any of the localities in question, and after estimating the probability of its accidental manifestation in vaccinated persons Leake concludes that the likelihood of the whole series of cases being due to natural causes is extremely small. This likelihood is further

reduced by the fact that in every case in which the sequence is known the level of the spinal cord first affected corresponds to the extremity into which the injection was made; that is to say, if the child was inoculated in an arm the paralysis developed in an arm, though not necessarily in the same arm. This is strong support, Leake adds, to other evidence that the virus of poliomyelitis is transmitted along nerve-fibres and not through blood or lymph; and he thinks the remarkably high fatality-rate may be attributable to close proximity between the part of the cord primarily infected and the nuclei corresponding to the muscles of respiration. His final conclusion is that "although any one of these cases may have been entirely unconnected with the vaccine, the implication of the series as a whole is clear," and many physicians may feel that it "renders undesirable the further use of poliomyelitis virus for human vaccination at present."

THE centenary of the University of London will be celebrated this year, probably from about June 29th to July 3rd, when many visitors from overseas will be attending the congress of the universities of the empire and the Anglo-American Historical Conference.

PUBLIC response to Canon Sheppard's broadcast appeal has ensured the despatch of a second British Red Cross Unit to Abyssinia for service on the north-western front. The general stores and the medical and surgical equipment and comforts will be completed by Jan. 18th, and it is anticipated that the unit will leave this country in the following week.

THE prizes for original research into rheumatism offered by the Soviet Government to the council of the Ligue Internationale Contre le Rhumatisme have been awarded to Dr. G. Kahlmeter (Stockholm), Dr. M. P. Weil (Paris), Dr. Ernst Freund (Vienna), and Dr. Bernard Schlesinger (London). As the prizes were offered by the Russian Government the communications submitted by Russian workers were not considered for the prizes; but those of Prof. Talalaef and Prof. Danischewsky were highly commended.

WE publish in another column an appeal for a recognition of the practical services of Dr. Rowland Fothergill on behalf of the medical profession in general. Dr. Fothergill's activities have been manifested within the official working of the British Medical Association, but his voluntary labours, through the Association, have helped to the formation of an effective medical organisation under the National Insurance Acts. Dr. Fothergill is giving up practice, and this is therefore a particularly appropriate time at which to make practical acknowledgment of the debt due to him from all. A Fothergill Testimonial Fund has been opened and subscriptions should be directed to the treasurer of the Fund, B.M.A. House, Tavistock-square, London, W.C.1.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of the fever hospital medical service group will be held at the house of the society, 1, Thornhaugh-street, Russell-square, London, W.C., on Friday, Jan. 31st, at 4 p.m., when papers on the serum treatment of typhoid fever will be read by Mr. A. Felix, D.Sc., and Dr. C. J. McSweeney. Dr. James Fenton left on Jan. 10th to attend the first South African Health Congress to be held at Cape Town, from Feb. 3rd to 8th. He represents the Royal Sanitary Institute (of which he is chairman), the Royal College of Physicians of London, and the Society of Medical Officers of Health.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXV.—THE PROGNOSIS IN DEAFNESS

I

THE causes of deafness may be broadly divided into (1) disease and degeneration of the perceptive apparatus, the cochlea, auditory nerve, and brain centres, the so-called nerve-deafness; and (2) affections of the conducting mechanism, that is, of the external auditory meatus and of the tympanum with its adnexa. It is with the latter group which is by far the more common that we shall deal first.

Conduction deafness is characterised, in distinction to nerve-deafness, by a greater loss of perception of low than of high tones of the scale, and by a greater loss of perception of sounds transmitted through the meatus, air-conduction, than of those transmitted by the bones of the skull, bone-conduction. Clinically, perception by bone-conduction may even seem to be better than normal, i.e., increased, though it appears from experiment in a perfectly sound-proof chamber that this is never actually the case. When the normal relation between air- and bone-conduction is so much altered that a tuning-fork is heard longer on the skull than at the meatus, Rinné's test is said to be negative; in cases of unilateral deafness of this kind, a tuning-fork on the middle line of the cranium is usually heard more loudly in the deaf ear and Weber's test is said to be to the affected side. But when the affection of the middle ear has only caused a slight diminution of hearing, not sufficient to invert the usual relation, Rinné's test will still be positive. Again, in middle-ear disease of long standing, as well as normally in old people, there is a tendency to degeneration of the internal ear and bone-conduction becomes shortened.

Obstruction of the External Auditory Meatus

This is an obvious cause of deafness. Hearing remains unimpaired as long as a small chink remains by which air and sound-vibrations can reach the drum; it is for this reason that the slow accumulation of wax often causes deafness of sudden onset. Deafness from obstruction by cerumen or eczematous debris is, of course, quickly relieved but, as these conditions are often accompanied by some degree of myringitis, the hearing does not always return to normal at once. The removal of foreign bodies may be easy or exceedingly difficult; in order to avoid the danger of injuring the drum, a general anæsthetic is often advisable, especially for children, except in the simplest cases, and a post-aural incision may be necessary. The prognosis should not be too optimistic until it is seen that the drum is unhurt; atresia may ensue if the meatus has been severely damaged. The meatus may be blocked by an exostosis, which here takes the form of a round pedunculated tumour; hearing is fully restored by its removal which is usually best performed through a post-aural incision. In cases of hyperostosis of the meatus, a condition in which three sessile bony outgrowths contract the meatus to a Y-shaped slit, the prognosis must be very guarded; removal is difficult and liable to be followed by stenosis, and the condition is apt to be accompanied by signs of nerve-deafness; it is usually wise to be content with keeping the meatal passage clear of debris, and fortunately the growth is very slow and rarely causes complete obstruction. The dilatation of stenosis due to injury is tedious and relapse is common, but it is possible

to restore a lumen sufficient for normal hearing; when, however, the meatus is completely occluded by scarring, the prognosis becomes uncertain, because it is impossible to know beforehand to what extent the tympanum has been damaged by the original traumatism. Congenital absence or atresia of the meatus is so often associated with malformation of the middle and/or internal ear that it is only worth while to attempt to make a meatus by plastic methods in the rare cases where the deformity is bilateral and bone-conducted sounds are well heard.

Deafness Due to Inflammatory Causes

With the exception of otosclerosis, a peculiar form of deafness to be considered later, the disease of the middle ear which causes deafness is almost always of the nature of an inflammation which passes along the Eustachian tube from the nasopharynx, and which shows an infinite variety of acuteness and virulence. The principal site of incidence of the inflammation, and of any resulting fibrosis, also varies, so that either the Eustachian tube, the drum-membrane, or the inner tympanic wall may bear the brunt of the damage; a lesion of the first is generally the most curable, while fibrosis in the region of the fenestræ causes the most severe and intractable forms of middle-ear deafness. It was formerly considered certain that the important path by which sound-vibrations are conducted to the cochlea is by way of the membrana tympani and chain of ossicles, but of recent years considerable doubt has been thrown upon this, and the theory has gained ground that the chief function of the ossicular chain is to damp and regulate the sounds.

ACUTE SUPPURATIVE OTITIS

The more virulent forms of inflammation usually produce a simple acute suppurative otitis; if infection be still more virulent, or be favoured by anatomical or constitutional factors, mastoiditis supervenes; in the most severe types, especially in those associated with the specific fevers such as scarlet fever, measles, or influenza in certain epidemics, the severe complications occur: sinus-thrombosis, cerebral abscess, meningitis, and labyrinthitis, the two latter causing severe deafness from damage of the internal ear, and all causing danger to life with which we are not here concerned. In the great majority of cases acute suppuration heals within three or four weeks under proper attention, and fortunately often even without it, leaving a healed membrane with a barely visible scar and no noticeable deafness, though some slight impairment compared with the other ear can more often be detected by careful tests. By proper attention is meant timely incision of the membrane when spontaneous perforation is delayed, and strict cleanliness of the meatus to avoid secondary infection. If the discharge fails to diminish in from two to three weeks, any nasopharyngeal infection must be treated, and especially should adenoids be removed in children and young people, for the ear will often become dry in a few days after this operation. If this treatment fails or is not indicated, and suppuration persists undiminished for three or four weeks, the simple mastoid operation should undoubtedly be performed even in the absence of all other symptoms; apart from the danger to life from the persistence of the suppuration (and quite extensive disease is

usually found in these cases) operation at this stage may be relied on in nearly all instances to leave an ear with an intact drum and little or no impairment of hearing. The longer that suppuration persists after four weeks, the more likely is deafness to result, and the greater probability is there of a permanent perforation of the drum which conduces to recurrence of the attacks.

ACUTE CATARRHAL OTITIS

Acute catarrhal otitis is the result of a less active inflammation and may show all grades of severity from a tympanum full of serous or mucoid fluid to a slight impairment of the patency of the Eustachian tube. As pain and constitutional disturbance are less marked, deafness is here a more obvious symptom; the patient often complains that his own voice echoes or sounds unduly loud, and musical tones are frequently heard out of tune which is a serious matter for musicians. Clinically, there may be much obstruction of the tube with or without secretion in the tympanum, or the latter may be full of fluid without any great Eustachian obstruction. Inflation gives marked relief; in young children politizerisation must suffice, but in adults inflation with the catheter is preferable. This must usually be repeated at intervals of one, two, or three days for some six to twelve times before cure is obtained. A single attack of acute catarrhal otitis nearly always ends in complete recovery of hearing, and often without treatment, but in some the hearing is left impaired; hence the importance of treating and keeping under observation all such cases until restoration is complete. Unfortunately attacks are liable to recur and sometimes to follow every cold, especially in children and young adults. This is a very frequent cause of chronic deafness, and every effort should be made to find and treat any predisposing cause in the nose or nasopharynx; adenoids are of all affections the most likely to be the source of trouble, but unhealthy tonsils, sinusitis, and nasal obstruction must not be overlooked. This does not mean that every septal deviation or spur should be removed, for here considerable judgment is required, but it is all-important that a healthy condition of the nose and throat be obtained. Occasionally an acute catarrhal otitis fails to clear up and a subacute condition remains in which a collection of fluid tends to persist in the tympanum. In such cases it is useful to suck out the fluid at regular intervals by means of a Weber-Liel tube passed along the Eustachian catheter, but if this fails to prevent its accumulation, the drum should be incised with careful antiseptic precautions and the secretion, usually a thick mucus, blown out with the catheter. This may seem a drastic form of treatment for a non-suppurative condition but, if it be allowed to persist, the hearing will be permanently damaged. Although the majority of cases of acute middle-ear inflammation recover without permanent deafness, the minority who suffer lasting damage are sufficiently numerous to form a large and important class of the community; frequently this is the result of severe destruction caused by scarlet fever. Closer attention to the acute forms of aural disease has already done much, but can do much more, to diminish their number; the public needs education on the importance of seeking skilled attention in these conditions, and especially on the harm which results from neglecting earaches in childhood.

CHRONIC MIDDLE-EAR DEAFNESS

Chronic middle-ear deafness may be the result of damage caused by former suppuration. Its degree

varies greatly with the site of the principal lesion; a perforation of the drum may be attended by surprisingly little disability, while fibrosis and adhesions within the tympanum, especially about the fenestræ, cause severe deafness. This fibrosis is very similar to the state of affairs found in non-suppurative chronic middle-ear catarrh, but with this difference, that it is usually not progressive. In some large perforations an "artificial drum" composed of a disc of cotton-wool moistened with liquid paraffin gives marked improvement of hearing. After the radical mastoid operation has been performed, the hearing is always below normal, but the effect of the operation is very variable and is difficult to estimate beforehand; if deafness is severe before operation, and especially when the ear is blocked by cholesteatoma or granulations, the hearing will probably be somewhat improved but, if the hearing has previously been fairly good, it is likely to be made worse. It is important, while operating, carefully to respect the inner tympanic wall in order to avoid scarring in this region.

CHRONIC CATARRHAL OTITIS

The commonest cause of chronic deafness is chronic catarrhal otitis, which is sometimes labelled chronic hypertrophic or chronic hyperplastic catarrh according to whether the principal lesion is thought to be a thickening of the mucosa or the formation of fibrous tissue; in any case they seem to represent different stages of the same process. The affection is probably always caused by former, usually repeated, attacks of acute or subacute catarrh, but, as the onset is very gradual and the normal perception is greater than is required in civilised life, patients seldom come for treatment until the deafness is advanced, while the attacks of otitis which have initiated the process frequently have occurred in childhood or youth and have been forgotten. The deafness usually tends slowly to increase, but there may be long intervals, even of many years, without progression, making it difficult to evaluate the effect of treatment. Attempts have been made in the past to remove scar-tissue and to loosen adherent ossicles by operation, but, apart from the danger of causing suppuration, results have not been permanent and such operations have been abandoned. Indeed, there is as yet no method of influencing fibrosis within the tympanum; obstruction in the Eustachian tube can, however, be favourably affected and, in some cases, cured by such treatment as the use of Eustachian catheters, bougies, and topical applications, and not infrequently inflation has a beneficial effect on the hearing even in the absence of noticeable obstruction. If a short tentative course of such treatment is found to produce progressive improvement, it should be persevered in as long as improvement continues; in this way a considerable proportion of cases can be brought to a higher level of hearing, and maintained there by occasional repetition of treatment. A short trial of such methods is always worth while, and sometimes gives improvement in unexpected cases. Mechanical oto-massage sometimes gives subjective relief, but is seldom found to produce a real or lasting improvement. Massage by means of sound waves, as produced by the electrophonoïde of Zünd-Burguet, is warmly advocated by some; it demands a long course of treatment and speedy relapse seems to be frequent.

ALCOHOLISM AND CRIME IN RELATION TO MANIC-DEPRESSIVE DISORDER*

By W. NORWOOD EAST, M.D., F.R.C.P. Lond.

H.M. COMMISSIONER OF PRISONS

THE terms mania and melancholia were used formerly to differentiate mental states which were looked upon as separate disease entities. Later, it was recognised that periods of mania and melancholia, of mental elation and mental depression, might occur as two stages in the same disease, and Kraepelin in 1896 introduced the concept of a manic-depressive disorder. It is unnecessary here to consider the various types of mental alienation which Kraepelin included in this term. He emphasised the important fact that although attacks might occur throughout the life of the individual they were not followed by pronounced mental enfeeblement. Indeed, the subjects of the disorder are frequently of good intelligence. Kraepelin associated the condition with symptoms of physical deterioration, but Kretschmer, Rehm, and others have found themselves unable to accept this view. Kretschmer seeks to connect certain physical states with psychological types and considers manic-depressive disorder to be associated with the *pyknic physique*.

A hereditary predisposition to mental disorder is an important aetiological factor in many manic-depressive subjects, and cases can be conveniently divided into two main groups. In one, the attacks appear to arise without any apparent cause; in the other, to be determined by a constitutional inability of the patient to adjust himself to accidental happenings which would present no such difficulty to a normal person.

The disorder consists of three phases: a state of mental depression, of mental exaltation, and a subsequent period of normal mental health. These phases may occur in variable order and may last for varying periods, and occur at irregular intervals. In both the depressed and exalted phases three fundamental symptoms are to be noted. In the depressed phase emotional depression, psychomotor retardation, and difficulty in thinking; in the exalted phase, emotional elation, psychomotor activity, and a rapid flight of ideas. In the depressed phase the patient experiences mental pain, the bodily movements and thought processes are slow, but consciousness is retained; the subject is aware of his surroundings and is often able to appreciate that he is mentally ill. In the exalted phase the patient has an exaggerated sense of well-being; he is over-active, restless, excitable, inconsistent, and changeable, and may be unable to exercise self-control. His memory may be clear, but his judgment is impaired and he does not realise that he is ill.

This brief outline of symptoms will require amendment if the disorder is present in an aggravated form. The most profound degrees of melancholia with stupor, delusions, and hallucinations may then be present; and in the alternating phase intense excitement, violence, and incoherence with delusions and hallucinations. On the other hand, the symptoms may be so slight in the milder cases as to escape notice either by the patient or his friends and associates,

and may pass by imperceptible gradations into normality. It is of particular medico-legal importance to remember that the temperamental level of many normal persons is not constant but rises and falls to lesser or greater heights from time to time, and it is a common experience to find among our personal friends and acquaintances some who for no assignable cause have their good and bad days according to the measure of their emotional variations.

Association with Crime

It will be apparent from these facts that the relationship of alcoholism and crime to manic-depressive disorder may be clear and unequivocal when the abnormal mental state is well-defined, but may be determined only by a skilled observer when normality is approached. How difficult it may be to form a correct opinion in the latter type of case was forcibly impressed on my mind many years ago when carrying out observations on prisoners who had been remanded from the police-courts on charges of attempted suicide, and in whom mental depression was attributable to external factors and alcohol had had been consumed in order to combat the affective state. A true assessment of the mental condition in such cases is important as a guide to the future, because manic-depressive disorder, it will be remembered, is recurrent. It should be remembered also in this connexion that an attempt at suicide in England is a misdemeanour for which a considerable sentence of imprisonment may be imposed. Further, in pre-war years, particularly it was frequently associated with alcoholism.

Crime, however, is associated with both major and minor manic-depressive states apart from alcoholism. Here again prolonged observation may be necessary before the mental condition underlying anti-social conduct can be disclosed. It must be noted also that criminal conduct in a manic-depressive subject may be unconnected with the abnormal phases of his life.

For example, a youth 20 years of age was sentenced to detention in a Borstal institution for stealing a motor-car. He was of foreign parentage and nothing of medical importance in the family history was admitted. He stated that his mother died when he was fifteen years old, and that he was much depressed at the time in consequence, and had suffered from at least five attacks of depression since then. He went to the United States of America and obtained work on a farm but stole a horse and was convicted and sent to an industrial school. He worked as a labourer on attaining his discharge, but in a few months was reconvicted for robbery and returned to the school. He was convicted later for stealing a motor-car and was deported to England. On arrival he stole a car with a man he became acquainted with on the voyage; they were arrested, and he received the current sentence. Immediately after arrest he came under the observation of experienced prison medical officers, and his mental condition was considered to be normal. A few months later he became rather unusually good-tempered and friendly; he was boisterous and appeared to have a surplus of energy. In a few weeks he became less aggressively purposeful. As time passed, although he continued to work well in the institution, he became quiet, disregarded his companions, and was uninterested in his surroundings. Two months later he became again unsettled, restless, talkative, aggressive, and mischievous. His memory at this time was unusually retentive, and a press of activity was noticed at work and throughout the various duties of the day. This phase passed off in a few weeks and he regained his normal mental level.

So far there has been no evidence to connect the criminal conduct directly with the mental disorder.

* A paper opening a discussion at the Society for the Study of Intebriety on Jan. 14th, 1936.

But it should be observed that some manic-depressive subjects are eccentric and unstable when they have attained their normal mental health and are then potential delinquents as a result of their mental constitution.

Manic-depressive disorder gives rise to criminal conduct apart from alcoholism. In one case a strictly abstemious man who had suffered from three previous attacks killed his wife in the depressed phase of a subsequent attack. The murder was unconnected with alcohol. The most important point to note here is the fact that crimes of violence are more frequent in depressed than in exalted states. I have pointed out elsewhere¹ that in a series of 53 depressed law-breakers 34 committed crimes of violence, and in a series of 52 exalted subjects only 7 were so convicted. Recent figures of insane homicides at Broadmoor criminal lunatic asylum show that 62 murders were associated with melancholia and 28 with mania.

It is generally accepted by those who are concerned with the administration of justice, and with the administration of penal institutions, that the proportion of first offenders who commit crime again is relatively small. It is also generally accepted that many others soon acquire a habit to commit crime which may be unconquerable. A manic-depressive subject may pass through phases of the disorder without committing any offence although some attacks are associated with crime, but personal experience leads me to believe that when the disorder is associated with alcohol the tendency to commit crime is materially increased. Further, the fact that crime was repeatedly associated in the same subject with manic-depressive disorder would lead me to consider whether alcohol was a contributory influence.

When repeated crimes are due to the disorder, and alcohol is not an added factor, the intervals of normal mental health may be free from the moral degradation which is to be observed not infrequently when the condition is associated with alcohol. A man was convicted of assaulting the police and was aggressive, offensive, contumacious, boastful, excited, and abusive when received into prison. He made false accusations against the staff and was unashamed when they were proved to be untrue. He appeared to be an unscrupulous and revengeful man, but his conduct and ethical standards were not inferior to those of his class in life when he regained his mental health.

In marked contrast is the case of a man who has been coming to prison for many years. He has been under treatment also in mental hospitals and has been diagnosed as a case of manic-depressive disorder by different alienists. His offences, which include theft, false pretences, assault, and drunkenness, have been attributable at different times to alcohol, to manic-depressive disorder, to both combined, and sometimes to a now well-established habit to commit crime. His reputation is such that those who know him are quite unable to place the slightest confidence in him at any time.

Association with Crime and Alcohol

When manic-depressive disorder is associated with alcohol and crime results the evidence of recent excessive drinking may be so overwhelming and that of the underlying mental disorder so insignificant as to escape demonstration. In such cases the past history of the individual may assist the diagnosis, and if there is reason to believe that previous conduct was due to manic-depressive disorder it may be desirable for those conducting the defence to call

medical evidence to support this view at the trial. In this event a medical witness will not belittle his position or the value of his evidence provided he submits his opinion as a possibility and without unqualified assurance. I do not mean to convey the impression that medical evidence should not be given with all the force that circumstances permit, but I have no doubt that some witnesses have not been as acceptable as they might have anticipated because they assumed more than they could substantiate and confused assumptions with facts.

A man was charged with the murder of his sweetheart in circumstances which left no doubt that he had committed the crime. The dead girl was found with a fatal wound in her throat and the accused lay a few yards away with a self-inflicted wound across the upper part of his neck. On reaching the hospital the house surgeon noted the man's breath smelt of alcohol, and he volunteered the statement that he killed the girl because she had been teasing him. This may have been true but was an inadequate motive, as indeed must be any motive for murder. The accused admitted that he had been drinking heavily for some little time before the crime, and there was corroboration of this as two days before he had been turned out of the girl's home as he arrived there in a drunken state. He was received into prison eleven days after the murder and was rational in conduct and conversation and showed no evidence of insanity then or whilst awaiting trial; but he made varying and contradictory statements at the medical interviews in order to suggest that he was of unsound mind. It is unnecessary to enter into these recitals here in detail, suffice it to say that it became quite clear that they could not be accepted. This conclusion was confirmed long after the trial; the prisoner then admitted to me that he had spoken falsely when he said he had no recollection of the circumstances connected with the crime. There was no evidence to support the view that the crime was the result of epilepsy, although this was put forward as a defence at the trial, apparently because the alleged amnesia was accepted. There was, however, reason to believe that the prisoner had suffered previously from periods of mental depression for which there appeared to be no external cause and which led him on one occasion to make an attempt at suicide. He combated these attacks by drinking to excess in order to gain confidence so that "he could feel himself as himself." Certain of his uncorroborated statements, if true, supported a diagnosis of alcoholic hallucinations, and the view that he was insane at the time of the crime. I was unable to go further than this in my evidence at the trial. The prisoner was found guilty of murder and sentenced to death, and was later reprieved.

The case presented difficulties inasmuch as the accused was clearly malingering insanity; it was also evident that the crime was related to alcohol, but it was less certain that it was associated also with manic-depressive disorder. I was able to observe the man during subsequent years in prison during which he passed through phases of mental depression which left no doubt that the crime was the result of alcoholic excess in a manic-depressive subject.

Association with Alcohol

Drunkenness may be associated with other forms of mental disease, with, for example, delusional insanity, dementia præcox, general paralysis of the insane, senile dementia, epilepsy, and high-grade mental deficiency. This society is chiefly interested in the association of manic-depressive disorder and alcoholism not involving criminal conduct. It is, however, quite impossible to draw any hard-and-fast line here as drunkenness, if followed by certain conduct, may itself constitute a crime and lead to the police-court.

More than 40 years ago Legrain² divided alcoholists into three classes: drinkers with an abnormal instinct,

defective moral sense, and want of moral equilibrium; drinkers with an abnormal tendency, including drinkers through taste, weak-mindedness, and want of mental equilibrium; and drinkers through impulse. In the last class were included dipsomaniacs and these were divided into pure dipsomaniacs and pseudo-dipsomaniacs. Pure dipsomania was defined as a "morbid condition, characterised by the irresistible obsession and impulse to drink coming on in attacks during which the patients are in a condition of impotence of will and manifest great anguish." Legrain observed that an attack of dipsomania might remain an isolated event in the life of the subject, but usually the attacks were repeated and assumed a periodical character. The concept of manic-depressive disorder had not been formulated at this time, but Legrain referred to the fact that Krafft-Ebing and others classified it among the periodical insanities, whilst other observers, struck by the depressed aspect of the patients especially at the commencement of an attack, saw in dipsomania a variety of melancholia. Pseudo-dipsomaniacs according to Legrain were drunkards who possessed a genuine desire to combat their craving, but were unable to do so through weakness of will.

We are concerned in this discussion with the periodic drinking associated with manic-depressive disorder, the true dipsomania of Legrain in which drinking is only an outward manifestation of underlying psychological, and perhaps physiological, causes independent of habit formation. The advisory committee to the Central Control Board in their work on Alcohol³ stated that:

"In these relatively infrequent cases, to which the name dipsomania is sometimes given, the patient drinks heavily for a period ranging in different cases, but usually of approximately constant length for the same case, and then, when the attack ceases or passes into another phase, he returns to sobriety—a fact, it may be noted incidentally, which goes to show that alcohol has no very strong habit-forming influence."

Too limited a view may be taken of dipsomania if the term is restricted to manic-depressive subjects, for some authorities consider that it may be related to epilepsy, and may also be the expression of a compulsion neurosis. The consumption of alcohol in manic-depressive disorder is connected directly with the current emotional state; in the depressed phase the patient has learnt by past experience its comforting effects; in the elated phase he is so joyous and expansive that he must share his happiness with others in extravagant festivity. In the former state the alcohol is consumed in order to avoid reality, in the latter to enhance it.

Segregation in Prisons and Retreats

The number of persons annually convicted of drunkenness is still considerable and the last figures published⁴ show how the year 1933 compares in this respect with recent years.

Year.	Convictions.	Year.	Convictions.
Average of } 1925-1929 }	66,858	1931	45,842
1930	57,131	1932	33,100
		1933	39,751

There was a continuous and rapid decrease until 1932, in 1933 there was a 20 per cent. increase over 1932, but the 1933 figure was still much below the figure for 1931 and earlier years. The number of persons received into prison for drunkenness, &c., during the last five years are as follows⁵: 1929, 7876; 1930, 8611; 1931, 7484; 1932, 5836; and 1933, 6631. No figures are available to show the number of those persons who are manic-depressive

subjects. The proportion is probably small, but the total may be not inconsiderable.

Persons are sent to prison as a punishment and not to be punished, and although it may seem illogical to-day to imprison anyone because his conduct is the result of a constitutional disorder over which he has no control, it is to be remembered that prisons serve also to protect the public, actually during the time the lawbreaker is detained, and potentially as the result of its deterrent effect. If binding over, fines, and probation have no effect on an offender whose conduct is a nuisance to society, imprisonment may be necessary ultimately even though he is not a serious menace to law and order.

Moreover, imprisonment may be the only means of protecting the manic-depressive alcoholic from himself. For it will be agreed that a large number are not certifiable, or are not certified, under the Lunacy Acts, others refuse to accept the provisions of the Mental Treatment Act, 1930, and enter a mental hospital as a voluntary patient, and others refuse to enter a retreat. On reception into prison they come under medical care and supervision and their return to normal mental health is expedited, partly as a result of medical treatment, partly because the orderly life is conducive to recovery, and also because alcohol and other causes of mental imbalance are no longer operative. It may be hoped that imprisonment will act sometimes as a deterrent also, if its imposition suggests to the subject that society not only disapproves of his conduct but considers he can amend it. However this may be, the patient and the public must be protected from the effects of his disordered mind, and although it may seem harsh, yet, in our present state of knowledge, temporary detention in a penal institution may be the only satisfactory method of dealing with some of these cases.

It will be known to the members of this society that the number of alcoholists detained in licensed retreats under the Habitual Drunkards Act, 1879, is almost negligible at the present time. The average for the period 1925-1929 was twelve; the number for the year 1930 was nine; for 1931, eight; for 1932, one; for 1933, seven; and for 1934, one.⁶ My experience as inspector under the Inebriate Acts leads me to consider that some manic-depressive alcoholists are suitable cases to deal with under the Act of 1879 if other alternatives are rejected and the reluctance of the patient to comply with the statutory provisions for admission can be overcome. The consequent restrictions may impress the patient with the importance of custodial care and encourage him to seek and persevere with treatment. There can be, of course, no objection to discharge the patient in appropriate cases before the full period of detention has expired.

MEDICAL TOUR OF MOROCCO.—On April 14th a party of medical men and their friends will leave for a tour of Morocco, which will include districts only recently colonised as well as the more usual sights. The party will return to Marseilles on April 21st. Further particulars may be had from Dr. R. Bernard, *Bruzelles-Médical*, 29, Boulevard Adolphe Max, Brussels.

MEDICINE AND THE LAW

Doctors and Dangerous Drugs

THE Home Office periodically circulates a list of medical practitioners, dentists, chemists, and veterinary surgeons from whom has been withdrawn the authority to possess, supply, or prescribe "dangerous drugs." The latest of these lists gives the names and addresses of 27 medical practitioners against whom the Secretary of State has made an order for this purpose during the past 14 years. The list states that in all but three cases a direction was simultaneously given that it should not be lawful for the named doctors to give prescriptions for the purposes of the Dangerous Drugs Regulations. Thus we get a summary of information (otherwise scattered over the arid columns of the *London Gazette*) as to the working of statutory control. The Act of 1920, giving permanent effect to certain war-time restrictions, confined the import, export, manufacture, sale, distribution, or supply of "dangerous drugs" to persons licensed or authorised. Home Office regulations, made under the Act, explain that certain classes of persons are authorised for this purpose—duly qualified medical practitioners, registered dentists, and veterinary surgeons and research workers in approved institutions in particular. This general "authority," however, does not entitle these privileged classes to possess or supply such drugs beyond what is "necessary for the practice or exercise of the respective professions or employments, in their capacity as members of their respective classes." Conviction for an offence under the Act of 1920 (or under the customs laws as applied by that Act) gives the Home Office a power to withdraw a person's "authority" by notice in the *Gazette*. If a doctor, dentist, or veterinary surgeon thus loses his "authority," the Home Office may, by like notice, direct that it shall not be lawful for him to prescribe dangerous drugs. It will be remembered that in 1926 a departmental committee on drug addiction considered and reported upon possible abuses discovered through the supply of exceptionally large quantities of morphine and heroin to particular practitioners or to individual patients on practitioners' prescriptions. The committee examined evidence tendered by the Home Office, the Ministry of Health, and the Director of Public Prosecutions, and considered possible remedies. It found the Home Office reluctant either to prosecute doctors in the police-court for offences against the Dangerous Drugs Acts or to bring such cases to the notice of the General Medical Council for disciplinary action. The reason for this reluctance was the fact that the issue would turn largely on questions of medical opinion. In the end the committee advised that these cases of alleged improper supply should, where the conduct of doctors was in question, be referred to a special medical tribunal. Regulations of 1928 gave effect to this suggestion and enacted that, if the tribunal so recommended, a doctor's "authority" might be withdrawn by the Home Office in consequence of adverse findings. It was a solution by no means unsatisfactory to the medical profession that the Home Office, accepting the advice of a departmental committee consisting entirely of physicians and surgeons, should have set up a medical tribunal to deal with these difficult allegations against professional men of possessing or supplying dangerous drugs for medical purposes which are not legitimate. So far as is known, no complaint is made of the manner in which the tribunal does its duty.

In relation to the huge total of medical practitioners on the Register, the number of 27 in the recent Home Office list is perhaps not a sensational proportion.

Murder by Bacillus

We must wait for the Indian mail to bring a full account of the judgment of the High Court in Calcutta on the appeal from the death sentences in the plague bacillus case. A rich Bihar land-holder was said to have died through plague infection injected into his body by a prick inflicted by a passing stranger in the waiting-room of a Calcutta railway station in November, 1933. Two men, the step-brother of the deceased and a doctor, were found guilty of conspiracy to murder. The Appeal Court has described the case as unique in the annals of crime. According to a telegram in the *Times* from its Calcutta correspondent, the death sentences were, on Jan. 10th, commuted to transportation for life partly because of the exceptional delay in hearing the appeal (the appellants having been under sentence of death for ten months) and partly because of the circumstantial nature of the evidence. It appeared that the two accused had conspired to provide some person at present unknown with plague culture which could not have been obtained except at Bombay. It is reported to have been an additional reason for commuting the sentences that this course may lead to the discovery of the actual perpetrator of the crime.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
JAN. 4TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2438; diphtheria, 1227; enteric fever, 25; acute pneumonia (primary or influenzal), 1684; puerperal fever, 31; puerperal pyrexia, 132; cerebrospinal fever, 29; acute poliomyelitis, 2; acute polio-encephalitis, 1; encephalitis lethargica, 3; dysentery, 23; ophthalmia neonatorum, 56. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 10th was 3818, which included: Scarlet fever, 1102; diphtheria, 1188; measles, 397; whooping-cough, 528; puerperal fever, 17 mothers (plus 12 babies); encephalitis lethargica, 280; poliomyelitis, 3. At St. Margaret's Hospital there were 16 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 48 (4) from measles, 6 (0) from scarlet fever, 21 (4) from whooping-cough, 39 (7) from diphtheria, 45 (12) from diarrhoea and enteritis under two years, and 110 (12) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza is rising, the total deaths for the last five weeks (working backwards) being 110, 80, 67, 62, 45. They are scattered over 62 great towns, Manchester reporting 8, Birmingham 6, Liverpool 5, Blackburn, Leeds, Bristol, and Walsall each 3; no other great town more than 2. Liverpool reported 15 deaths from measles, Manchester 9, no other great town more than 2. Liverpool also had 6 deaths from whooping-cough. Deaths from diphtheria were reported from 25 great towns: Liverpool 6, Hull, Manchester, Newcastle-upon-Tyne each 2. Bradford reported the only death from enteric fever outside London.

The number of stillbirths notified during the week was 270 (corresponding to a rate of 38 per 1000 total births), including 53 in London.

SOCIETY FOR THE PROVISION OF BIRTH CONTROL CLINICS.—On Friday, Feb. 7th, at 6 P.M., Dr. Gladys Cox will give a lecture on the theory and practice of contraception, which will be followed at 7 P.M. by a practical demonstration. The lecture will be given at the Walworth Women's Welfare Centre, 153A, East-street, London, S.E. Tickets should be obtained in advance from the centre.

OBITUARY

**ALBERT ALEXANDER GRAY, M.D.,
F.R.F.P.S. Glasg.**

THE death on Jan. 4th at his home in the West Highlands of Dr. Albert Gray, at the age of 67 years, removes an otologist whose name was known to his fellow workers throughout the world.

Albert Alexander Gray was born at Pollokshields, Glasgow, son of William and Margaret Gray (née Pace), and was educated at Bootham School, York, Oliver's Mount, Scarborough, and Glasgow Academy, qualifying M.B., C.M. Glasg. in 1890. Within the next ten years he took the M.D. Glasg. and the fellowship of the Faculty, and was elected F.R.S. Edin. After a house surgeoncy at the Glasgow Royal Infirmary he spent two years in general practice in Blackburn and then

studied in Leipzig and Munich before returning to Glasgow to specialise in diseases of the ear, nose, and throat. He was appointed aural surgeon to the Central Dispensary and lecturer in the University on diseases of the ear, contributing regularly to the *Journal of Anatomy and Physiology*, so that even before his appointment as aural surgeon at the Infirmary he came to be recognised as an otological authority.

DR. ALBERT GRAY
(Photograph by Annan)

The story of Gray's career as an investigator is part of the history of scientific otology. His early work was designed to overcome the formidable technical difficulties still obscuring many fundamental questions of the ear's finer structure. His first major achievement was a notable improvement in the technique of preparing casts of the membranous labyrinth (1904). This method he proceeded to apply on a wide scale in those studies of the comparative anatomy of the inner ear, the fruits of which were seen in his first classic work, "The Labyrinth of Animals," published in 1908. The results therein presented display a mastery of histological and photographic technique which has remained unsurpassed to this day. By this early mastery of anatomical method Gray provided himself with a weapon the power of which was to be continuously demonstrated in the years to come. With the instinct of the true biologist, however, he regarded anatomy as no more than a means of attack upon problems of function. In 1900 he published his observations upon the differentiation in size and density of the spiral ligament of the cochlea, putting forward the theory of maximum stimulation which has stood the test of time. His views on the physiology of hearing are embodied in the "Mechanism of the Cochlea" (1924), written in collaboration with Mr. G. Wilkinson. His "Atlas of Otology" (1924 and 1933) displays the same technical perfection and sound biology. In the sphere of

pathology, apart from his pioneer study of the changes in deaf-mutism, Gray was chiefly known for his work on otosclerosis. His book with this title (1917) combined careful clinical observation and good pathological method in a way unusual at the time. His more recent work was set out in his Dalby lecture (1934), and the book on the treatment of otosclerosis published just before his death. Recognition of his standing as a scientific otologist came to Gray at many periods of his career: it included the Lenval prize of the International Congress of Otology (Budapest, 1909), the gold medal of the American Academy of Ophthalmology and Otology (1911), the Guyot prize of the University of Groningen (1929), and many others. He was elected president of the section of otology of the Royal Society of Medicine in 1914 and of the International Collegium Otolaryngologicum Amicitiae Sacrum in 1929.

Dr. Gray had married in 1892 Mabel Henderson by whom he had two sons, of whom the elder is now head master of Bootham School and the younger is in practice at Haslemere. On his wife's death in 1927 he gave up his work in Glasgow and retired to London where he became librarian and curator to the Ferens Institute of Oto-Laryngology at the Middlesex Hospital. Of his work there "S. H." writes: "Except for holidays in Scotland, Gray spent almost the whole of his time in the Institute, often remaining at work until well after midnight, because the freedom from traffic and vibration provided the best conditions for the high-power microphotography by which he illustrated most of his contributions. He soon became the father of the laboratory, his counsel and advice being constantly sought and freely given. He worked because he enjoyed working and his enthusiasm spread to all with whom he came in contact. He had in high degree the gift of exposition, making a difficult and technical subject both clear and interesting, and his demonstrations at the Institute and at meetings of the otological section and of the collegium were appreciated by all who heard them. Gray has done more than anyone in this country for scientific otology. He has demonstrated that the best, if not the only, line of advance lies in the careful study of deafness during life followed by high-power magnification of serial sections after death. It is greatly to be regretted that the valuable work on which he was still engaged should have come to this abrupt end."

JAMES WOOD, M.D. Manch., D.P.H.

Dr. James Wood, who died on Jan. 3rd at the age of 62, had been for some time in ill-health but continued to discharge his duties as M.O.H. for Chadderton until two years ago. Born at Oldham and educated subsequently at Wesley College, Sheffield, and the University of Manchester, he graduated as M.B., Ch.B. in 1896, and proceeded later to the M.D. degree, taking also the diploma of D.P.H. of the Irish royal colleges. After holding several resident appointments and being for a few years in private practice, he was appointed in 1911 assistant M.O.H. at Oldham. Two years afterwards he became M.O.H. of Chadderton, and discharged the duties to public satisfaction until a breakdown in health occurred in 1934. He was then given leave of absence and never resumed duty. Dr. Wood was known in the neighbourhood, in addition to his valuable public services, as a particularly fine cricketer.

RONALD GEORGE CANTI, M.D. Camb.

THE death after long illness of Dr. Canti, the well-known pathologist, occurred at his home in Hampstead on Jan. 7th. He was a pioneer in scientific research, a popular and effective teacher, and an untiring and unselfish worker. His death at the age of 52 is a matter of public regret.

Ronald George Canti was the son of Mr. G. F. Canti, and was born in London in 1883. He was educated at Charterhouse and entered King's College, Cambridge, in 1902. He received his medical training at St. Bartholomew's Hospital, took the English conjoint diploma in 1911 and graduated M.B. Camb. in 1915, proceeding later to the M.D. degree. At St. Bart.'s, after serving as house physician, he became a demonstrator of pathology under the late Sir Frederick Andrewes, the starting-point of a laboratory career which was to develop along lines which no one could then have foreseen. Overshadowed as they were by his subsequent achievements, his earlier contributions to knowledge included a number of useful and diverse studies, embracing such subjects as the urea content of the cerebro-spinal fluid, the morbid anatomy of pulmonary tuberculosis in childhood, and the bacteriological findings in cerebro-spinal fever. In connexion with these it should be observed that he was the first English worker to demonstrate that the urea content of the cerebro-spinal fluid rises with that of the blood, the first to

confirm Ghon's observation that tuberculosis of mediastinal glands is always secondary to a focus in the lung, and one of the earliest to recognise that meningococci identical with those causing a meningitis are to be found in the nasopharynx during the course of the disease.

The work by which Canti is best known began in association with the late T. S. P. Strangeways and centred on the behaviour of the malignant cell under irradiation. Over and above the pursuit of this study by in-vitro methods, he undertook with Dr. Malcolm Donaldson an exhaustive histological investigation of uterine carcinoma at various stages during and after irradiation, which is among the earliest and most thorough of its kind. But his principal achievement was in bringing the behaviour of tissue cultures within the range of ordinary vision. Direct observation could not be continued over such periods as are occupied by the process of growth in a tissue culture; photography could conceivably take its place, and photographs would not merely provide a permanent record, but if taken at long intervals and projected at the speed of cinema film would condense the protracted and sluggish events of perhaps three days' growth into an animated but nevertheless faithful reproduction lasting only a few minutes. The apparatus by which this result was in fact achieved, first built by Canti himself in his own house, was a marvel of ingenuity, and the technical excellence of its photography excited widespread admiration,

These films enabled many thousands who would never otherwise have had more than the vaguest conception of the individual living cell to gain a vivid idea of its activities. The potentialities of this method of observation have perhaps yet to be fully explored, but wherever tissue culture can serve the purposes of future research the machine devised by Canti will remain indispensable to its prosecution.

Among Canti's numerous other interests were his scientific secretaryship of the British Empire Cancer Campaign, which included the organisation of a highly successful conference in December, 1934, and his position as chief medical adviser to the London Blood Transfusion Service, an organisation which he helped very largely to bring to its present size and efficiency. His appointments included that of lecturer in bacteriology at St. Bart.'s, which he relinquished in 1930 to become clinical pathologist to the hospital and lecturer in clinical pathology, those of pathologist to the Alexandra Hospital, Swanley and to the Florence Nightingale Hospital, and of bacteriologist to the City of London. In the interstices of this public work he was a clinical pathologist enjoying a reputation in some ways unique for acumen and soundness of judgment, and for his capacity to apply the latest available methods to the problems of diagnosis and treatment.

Apart from his wide and diverse knowledge of many ancillary subjects, from engineering to pure

physics, the attribute which served Canti best in his principal achievements was a light-hearted courage in the face of technical difficulties which no living man can have equalled. Behind this was an insatiable curiosity and a catholic interest in all things biological. To him nothing seemed impossible, and he was ready to turn to account in the laboratory a new discovery in almost any sphere. His visit to New York in 1925 to learn a new technique for studying the bacteriology of influenza provided a fresh stimulus to a mind of rare enterprise, and contributed to that ultra-modernity of outlook which was prepared for anything in the cause of progress. This imaginative capacity and an almost boyish enthusiasm were the most striking qualities in a vivid personality. His enthusiasm spilled over to the work of others, and many junior colleagues are indebted to him for unsparing help and stimulating encouragement. Both in the laboratory and in his practice he was inexhaustibly generous when his services were needed. He had a wide circle of international as well as of home friendships; he will be remembered by all as a brilliant personality and a supreme technician, and by many as a most lovable friend.

Dr. Canti married in 1912 Clara Eyles, who nursed him throughout a long and distressing illness. He leaves four children: a daughter, a son who has followed his father to King's College, Cambridge, a second son who is a student at the Royal Veterinary College, and a third son who is a student at St. Bartholomew's Hospital.

DR. CANTI

JOHN GEORGE GRANT, L.R.C.P. Edin.

Dr. J. G. Grant, of Miavaig, Stornoway, who died on Dec. 26th, had been in ill-health for a long time and his premature death was directly connected with his arduous work as a medical officer in the Highlands and Islands medical service. He received his medical education at Anderson College, Glasgow, working also in Edinburgh and at the London Hospital, and took the double diplomas of Edinburgh and Glasgow in 1899. He practised for a time in Canada, but some 20 years ago he succeeded Dr. Donald Murray as M.O.H. for Stornoway and the parishes of Uig and Lochs, a district presenting great geographical difficulties to the practitioner. The discharge of his onerous duties, complicated by the bad conditions of transport, especially in winter, tried Grant, but relief was obtained by the division of his area during the latter part of his life. He was now responsible for West Uig only, while the opening of a new high road eased the water journeys. But by this time he had practically broken down under the strain, and a lingering invalidism led to his death at the age of 60.

MABYN READ, M.D., D.P.H. Camb.

Dr. Mabyn Read, whose death occurred on Jan. 2nd, was for many years M.O.H. for the city of Worcester. As he became connected with the public health of Worcester nearly half a century ago he saw the whole of modern sanitary administration develop in the cathedral city.

Born at Falmouth he went to Christ's College, Cambridge, as a natural science scholar, and graduated with honours in the Natural Sciences Tripos in 1876. He proceeded to St. Bartholomew's Hospital for his medical education, and graduated as M.B. Camb. in 1880, later taking the diploma of D.P.H. and the M.D. degree. He acted as house physician both at St. Bartholomew's Hospital and Great Ormond-street Children's Hospital, and in 1891 was appointed M.O.H. of Worcester; as this was, as usual at that date, a part-time appointment, for the first 20 years of his residence in Worcester Dr. Read carried on private practice, but in 1912 he became a full-time officer and held the post for 17 years, retiring in 1929. As will be seen by these dates, the main evolution of modern sanitation went on under his eyes and largely under his administration, the official care of infants, the school medical and tuberculosis services all being initiated during his term of office. He was particularly interested in maternity and child welfare activities, and was rewarded by seeing the infant death-rate of the city substantially reduced, a practical issue to his enthusiastic labours.

CLEMENT JOHN GOODHUGH WHITE, M.B., B.Chir. Camb.

THE sudden death occurred on Jan. 6th of Dr. John White, resident surgical officer at St. Bartholomew's Hospital, Rochester. He was found dead in the hospital in circumstances that necessitated an inquest, which has been adjourned in order that certain analyses may be performed.

C. J. G. White was the son of Dr. Clement White, honorary surgeon at St. Bartholomew's Hospital, Rochester, and was 27 years of age. He was educated at Felsted and Christ's College, Cambridge, where his father had been before him, and graduated in arts with honours in the Natural Sciences Tripos, proceeding for his medical education to the Middlesex

Hospital. He took the English conjoint diplomas in 1933, and graduated as M.B., B.Chir. Camb. in 1935. At the hospital he served as house physician and resident officer in the ear, nose, and throat, and in the orthopaedic departments, and in his work showed himself diligent, conscientious, and possessing sound judgment. His geniality and good nature combined with his clinical insight enabled him to fill his resident posts with unusual success, while his qualities as a sportsman further added to his popularity, for while at Middlesex he was secretary and captain of the hockey club. After leaving Middlesex Hospital he acted as obstetric and gynæcological house surgeon at Queen Mary's Hospital, Stratford, and then, after six months' experience as a ship's doctor, he obtained the post of resident surgical officer to St. Bartholomew's Hospital, Rochester. The reasons of his sudden death are now under inquiry, but none of the evidence given at the inquest pointed to anything but a fatal accident, for he was to all appearance a perfectly happy young man, successful in his career, in excellent health, and with no financial or other private trouble. We have received from the Middlesex Hospital medical school an eloquent tribute to his popularity at the Middlesex Hospital: "Jack White will always be remembered by those who knew him for his cheerfulness, good nature, enthusiasm, and other personal qualities which go to the making of a most kindly and understanding doctor."

JEREMIAH REIDY, M.D., D.P.H.

Dr. Jeremiah Reidy, who died on Jan. 6th at his home in Blackheath Park, practised in Stepney for 30 years, and was well known in both public and professional capacities.

Jeremiah Reidy was born at Gardenfield, Limerick, and was educated at University College, Cork, proceeding for his medical studies to Dublin and Glasgow. He took the double Scottish diploma in 1898 and attended classes at the London Hospital, after which he became clinical assistant at the Royal Eye Hospital, Southwark, the Royal Chest Hospital, and the Blackfriars Hospital for Diseases of the Skin. He then graduated as M.B., B.Ch. R.U.I., taking also the D.P.H. in 1912. Two years later he proceeded to the M.D. degree, when he secured the gold medal in medicine. He had now been established for some time in Stepney and was conducting a large practice, while he was also surgeon to the H Division of the Metropolitan and Thames Police. In the year 1917-18 he was mayor of Stepney and was appointed a J.P. of the County of London. In Dr. Reidy the profession has lost an able practitioner and the public a useful servant.

NEW HOSPITAL AT EAST GRINSTEAD.—East Grinstead's new hospital was opened on Jan. 8th by Princess Helena Victoria, and received its first patients on Jan. 14th. The hospital is situated on the East Grinstead-Holtze road, not far from the town, and it will meet the great need which has been felt for many years. It replaces the Queen Victoria Cottage Hospital which was opened as a memorial of a former Royal Jubilee, and which only contained 12 beds for adults, 3 cots for children, and one room for a paying patient. The new hospital, which cost about £29,000, has accommodation for 12 men, 12 women, 6 cots for children in their own ward, and 6 paying patients; it also contains an operating theatre, X ray room, and accommodation for the staff. After the opening ceremony and the dedication service conducted by the Bishop of Chichester, the Princess received purses from 150 children.

CORRESPONDENCE

THE CONTROL OF MEASLES

To the Editor of THE LANCET

SIR,—In his interesting paper in your last issue (p. 103) Dr. J. A. H. Brincker states that the first attempt to modify measles was made by L. Weissbecker 40 years ago. As a similar statement was made in an editorial article in the *Journal of the American Medical Association* of August 17th, 1935, it is well to emphasise the fact that inoculation against measles was first carried out nearly two centuries ago by Frances Home (1719–1813), first professor of *materia medica* in Edinburgh, who is best known for his “*Inquiry into Nature, Cause, and Cure of the Croup*” (1765). In an article in his “*Medical Facts and Experiments*” (1759), entitled *Of the Measles as they appeared 1758 and of their Inoculation*, Home wrote: “I thought that I should do no small service to mankind if I could render the disease more mild and safe in the same way as the Turks have taught us to mitigate the small-pox.” Home’s method was as follows: A superficial incision was made where the eruption of measles was thickest, and the blood was received on cotton-wool which was applied to incisions on both arms of the child to be protected and allowed to remain on three days. Of 12 children, aged from 7 months to 13 years, in whom this method was employed three had no rash at all and were regarded by Home as failures, though we should probably regard them as examples of complete protection, while in nine the attack was much milder than usual.

Home’s method was subsequently employed by observers in different countries with varying results. In 1789 Thomas Percival (“*Essays Medical, Philosophical, and Experimental*,” 1789, ii., 69), after alluding to Home’s method, stated that “the morbillous matter has since been ingrafted by means of lint wet with the tears from the eyes in the fresh stages of the disorder.” Percival however did not give any information as to the success of this experiment. Von Jürgensen (Nothnagel’s *Encyclopædia of Practical Medicine*, 1902, art. measles), who is sceptical as to the success of Home’s experiments, quotes Thomassen à Thuessink, who attended Home’s clinic in the Edinburgh Hospital in 1784–5, and failed to see the successful results described. According to Guersant and Blache (*Dictionnaire de Médecine*, 1832–1846, art. Rougeole) Home’s experiments were repeated at the Philadelphia Hospital in 1801 but without success, although trials were made with blood, tears, and nasal and bronchial mucus, and with a similar result by Locatelli. On the other hand, Prof. Speranza of Mantua (*Jour. der pract. Heilk.*, 1827, lxiv., 124) in 1822 inoculated six boys and himself, and a mild attack of measles resulted in each case. Home’s method, however, was carried out on the largest scale by a Hungarian physician, Michael von Katona (*Österreich. med. Woch.*, 1842, No. 29, p. 697), who stated that during a malignant epidemic of measles he had successfully inoculated 1122 individuals, 7 per cent. escaped an attack altogether, and in the rest it was very mild.

An interval of nearly 50 years elapsed between the publication of Katona’s paper and the appearance of another communication on the same subject. In a paper read before the Glasgow Medico-Chirurgical Society on March 21st, 1890 (*Glas. Med. Jour.*, 1890, xxxiii., 420), entitled *Inoculation, with sug-*

gestions for its further application in medicine, especially in mitigating the severity of measles, Dr. Hugh Thomson, vaccinator to the Faculty of Physicians and Surgeons, Glasgow, and to the Glasgow Royal Infirmary, after giving an account of Home’s, Speranza’s and Katona’s experiments, recorded his personal experience of two cases in which he employed Home’s method. As no eruption ensued, but only slight catarrhal symptoms, Thomson regarded his cases as failures, but like the three cases of Home previously mentioned they were probably examples of what would now be called an attenuated attack.

Further information about Frances Home will be found in a paper (*Proc. Roy. Soc. Med.*, 1927–8, xxi., 1013) by the descendant the late Fleet-Surgeon W. E. Home, a frequent contributor to your columns.

I am, Sir, yours faithfully,

J. D. ROLLESTON.

London, S.W., Jan. 11th.

GASTRIC ACIDITY AND ITS SIGNIFICANCE

To the Editor of THE LANCET

SIR,—Prof. F. L. Apperly’s paper on gastric acidity in your issue of Jan. 4th is of great interest, but some of his conclusions to which you refer in your annotation are certainly erroneous.

I have analysed the data obtained in a consecutive series of 41 anæmic patients at New Lodge Clinic who had both a blood count and a test-meal in the few days preceding a transfusion. No less than 33 secreted free hydrochloric acid, including 17 with acidity above normal. They included 21 cases of anæmia following hæmorrhage from an ulcer. Some of the others were cases of very chronic anæmia, including 1 of Hodgkin’s disease and 3 of aplastic anæmia. In one patient with aplastic anæmia, who has led a fairly active and comfortable life as a result of having about 250 transfusions in the course of eight years, hyperchlorhydria is still present, though his hæmoglobin rarely exceeds 50 and has been as low as 26 per cent. In seven cases the hæmoglobin percentage was under 30, in six between 31 and 40, in nine between 41 and 50, in seven between 51 and 60, and in the remainder between 61 and 66—all having a degree of anæmia which, according to Prof. Apperly, should give rise to achlorhydria.

Only 8 of the 41 patients had achlorhydria; of these 3 had Addison’s anæmia, 3 carcinoma of the stomach, 1 polyposis and carcinoma of the colon, and 1 microcytic anæmia which appeared to be a sequel of achlorhydria following gastro-jejunostomy. Certainly in 6 and probably in all of these cases the achlorhydria preceded the development of the anæmia. In an unselected series of 41 anæmic patients there was thus no single case which gives any support to Prof. Apperly’s statement that achlorhydria is likely to result when the hæmoglobin falls below 66 per cent. of the normal.

Prof. Apperly suggests that it is necessary to distinguish between achlorhydric anæmia and his hypothetical anæmic achlorhydria, but I believe that all cases in which anæmia is associated with achlorhydria the anæmia is either a result of the gastritis, which also causes the achlorhydria as in Addison’s anæmia (Faber, Castle), or the anæmia is a result of deficient utilisation of the iron in the food owing to the achlorhydria or the associated enteritis (Faber, Witts). Prof. Apperly also suggests that asthma will be found

to raise the gastric acidity. But Glanvill and Cosin found that in 15 of my cases at Guy's Hospital and 52 at New Lodge Clinic curves below the average normal occurred 20 per cent. more frequently than among normal people, 12 per cent. having achlorhydria. Marjorie Gillespie in a series of 109 asthmatic patients found that 51.5 per cent. had acidity below normal, compared with 19 per cent. of 2448 cases collected by Hartfall from New Lodge Clinic, and 15.5 per cent. had achlorhydria. Low acidity is still more frequent among children; thus Bray found that 9 per cent. of 200 children had achlorhydria, 48 per cent. hypochlorhydria, and 23 low normal curves. I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, Jan. 11th.

MATERNITY NURSES AND MIDWIVES

To the Editor of THE LANCET

SIR,—In your issue of Nov. 16th, 1935, appeared a letter from Dame Janet Campbell in which various problems connected with the proposed salaried midwifery service were offered for solution. Among these, the most urgent would seem to be: How are the competing claims of the medical student and pupil midwife for the use of clinical facilities to be reconciled? When medical authorities are urged to improve the training in obstetrics of medical students, they invariably reply that the chief obstacle is the comparative scarcity of material, the cases which they so greatly need being absorbed by the training of over 3000 pupils annually, for the Central Midwives Board examination. Of these, more than 50 per cent. do not propose to practise midwifery, and the experience to be gained by, at the lowest computation, 30,000 of these all-important maternity cases is being thrown away on candidates already dedicated to a totally different branch of service.

A medical student and a pupil midwife may not count the same case in their obligatory roll of 20. This rule does not, for obvious reasons, apply to the training of maternity nurses. If, therefore, as Dame Janet suggests, England were to copy the example of Holland—already well ahead of her in this matter—and were to institute a registered service of maternity nurses, the legitimate aspirations of our hospital nurses, to learn how to care for mothers and their infants during and after childbirth, would be satisfied, and the gain to medical students and pupil midwives greater than is at present realised. Simultaneously, the training of the latter might with advantage be lengthened to a two years' course—already current in many, if not most, European countries. This would automatically reduce the number of midwifery pupils to a very large extent, their place being taken in hospital wards by the pupil maternity nurses.

In Holland maternity nurses who already possess State registration for general nursing are allowed to take a six months' course, twelve months being prescribed for those without this qualification, and this has been proved to answer admirably. It is sometimes urged that the only way to abolish the dangerous "handy woman" is to penalise the care of motherhood to all but certified midwives, but it is obvious that a class of registered maternity nurses would answer the same purpose, perhaps even more effectually.

I am, Sir, yours faithfully,

ALICE S. GREGORY,

Hon. Secretary, British Hospital for Mothers and Babies, Woolwich.

Jan. 13th.

WHOOPING-COUGH AND VACCINE

To the Editor of THE LANCET

SIR,—I should like to thank Dr. Begg and Dr. Coveney for the way in which they have, in your issue of Jan. 11th, set out the data of their vaccine treatment of whooping-cough. Sufficient details are given to enable the reader to criticise. Often enough no notes of dose or preparation of vaccine are given, so that when failures are reported, one is left wondering whether it was indeed the vaccine which was at fault.

Knowing nothing of the vaccine treatment of whooping-cough, I assume that it can be compared to that of any other disease of a mildly chronic type, a disease, moreover, which may begin acutely and then pass through a subacute stage. The authors of the above paper make the following statement: "It is generally agreed that, if success is to follow vaccine therapy, the initial injections must be given early in the disease, large doses must be injected. . . ." Treatment along these lines is justified, as has been shown by W. H. Wynn (Brit. Med. Jour., Jan. 11th, 1936) in his treatment of pneumonia, but large doses may only be given before the patient is sensitised to pneumococci, which, according to Wynn, begins to happen on the fourth or fifth day. On their own showing, however, the whooping-cough cases treated by Dr. Begg and his colleague had already reached the paroxysmal stage of the disease. In order to justify the large doses of vaccine used, it would be necessary to show that no specific antibodies had already been formed—i.e., that the cells had not become sensitised. In any case, the doses advocated by Wynn (60 to 600 million) are less than a twentieth of those given to the children (all under the age of ten).

A few years ago I made some estimations of the dried weight of bacterial vaccine. Roughly 4000–5000 million dried coliforms weighed 1 mg., or 5000–6000 million streptococci or staphylococci. Probably the very small *B. pertussis* might run to higher figures, but certainly not more than 8000 million. Drs. Begg and Coveney in 14 days gave children doses up to 2 mg. and, in all, the equivalent of 6 mg. of dried bacterial substance. Compare this with tuberculin, as Wynn aptly does in the paper quoted above; 1 c.cm. (containing 1 mg. ?) would not affect a normal child, but 0.000001 c.cm. might cause reaction in an infected person. Translated into terms of pertussis vaccine:—

Eight thousand million to a normal person = reaction —
Eight thousand only to an infected person = reaction ±

Comparable too with tuberculosis is the vaccine treatment of chronic rheumatism. At the Charterhouse Rheumatism Clinic, in order to minimise reaction, amounts varying from under 1000 up to about 200,000 organisms are given. This range of dosage was also recommended by the B.M.A. committee on arthritis, when referring to my vaccine. For estimating dosage, perhaps we may assume that whooping-cough in the paroxysmal stage lies between the extreme of acute pneumonia on the one hand and chronic arthritis on the other. Optimum doses might reasonably be considered to range from (say) 50,000 to 500,000 or one million. Drs. Begg and Coveney envisage a further investigation. Let them try such a range and use their present method as a control.

To the unbiased reader the surprising thing is that the vaccine cases so closely approximated to the controls. Here must have supervened the mechanism which a merciful Providence seems to have provided whereby the reaction from a heroic dose of vaccine

can only be the maximum and that any bacterial substance in excess of the amount necessary to provoke this does no further harm, beyond perhaps immediately neutralising the antibodies produced.

I am, Sir, yours faithfully,

London, W., Jan. 13th. H. WARREN CROWE.

THE UNDESCENDED TESTICLE

To the Editor of THE LANCET

SIR,—I have been discussing the question of medical and surgical undescended testicles with Dr. Spence and Dr. Scowen, and we have decided to break away from professional tradition and have a look at some of each other's cases. I hope to convince them that the arguments on which I submit cases to operation are not entirely irrational, and that the results are much better than they imagine them to be. On the other hand, if they convert a case for which I should recommend operation into one for which I should not, I shall most willingly admit it as a postscript to their next report.

I am, Sir, yours faithfully,

Queen Anne-street, W., Jan. 13th. DENIS BROWNE.

A VASOVAGAL ATTACK

To the Editor of THE LANCET

SIR,—I was interested in Dr. Gumpert's note published in to-day's issue of THE LANCET because I recently had a similar experience.

A middle-aged patient was brought to me on Dec. 21st, 1935, by Mr. J. Ross McNeill, of Norbury, with a history of fainting attacks associated with bradycardia. Just as I was preparing to take a tracing he suddenly had a faint, and the electrocardiogram, as in Dr. Gumpert's case, showed a slow rhythm (40) with complete absence of P-waves. A second tracing taken about a quarter of an hour later showed a normal rhythm.

I am, Sir, yours faithfully,

Queen Anne-street, W., Jan. 11th. T. W. PRESTON.

A BOOK REVIEW

To the Editor of THE LANCET

SIR,—I have read with much interest the review (THE LANCET, Nov. 23rd, 1935, p. 1183) of the new edition of Jelliffe and White and especially the remark that too great a proportion of the book has been given to the vegetative nervous system (suprarenals et al.) as compared with neurosurgery, for example, i.e., tumours of the spinal cord, radiography, &c. Dr. White and I believe that suprarenal difficulties are strictly neurological problems; especially asthenic states are more frequent and important than spinal cord tumours, hence a greater space is given to them. One of our special problems was this statistical one of proportionate involvement of this or that organ or organic function—i.e., disease—and we have tried to follow such a balanced programme in our book.

We think your reviewer distinctly in error when he says we give only "six words" to the subject of encephalography in the diagnosis of cerebral tumours, no doubt referring to the six words on p. 785. How about the 20 words on p. 778? and I might refer to a number of places throughout the book where Röntgen ray methods are emphasised. As this work is not one on neurosurgery this type of special study is naturally only mentioned as desirable or necessary. The roentgenologist does most of the film interpreting for spinal cord tumours, brain tumours, &c.

When further your reviewer states that "subacute combined sclerosis" is not clearly differentiated from a motley group of "combined scleroses," is this true? And when he says it is "mainly in the realm of recent

developments in neurology that the shortcomings of the book are to be found," would it not have been of service and as evidence of good faith to mention some of these that are omitted?

I am, Sir, yours faithfully,

New York, Dec. 20th, 1935. SMITH ELY JELLIFFE.

OEDEMA OF THE ANKLES AND AIR TRAVEL

To the Editor of THE LANCET

SIR,—On a recent visit to England by air I was rather startled to find that by the time we had reached Brindisi my ankles had become very œdematous. I was feeling at the time particularly fit and there was no sign of any renal or cardiac mischief. On inquiring from my fellow travellers, I was relieved to find that the majority also had some degree of œdema of the ankles. Moreover, not all the passengers had started from Johannesburg. Some of them had joined up in British East Africa and the Soudan. The œdema passed off after the first few days in London, but on the return trip my ankles again became œdematous. Inquiry also showed that some of the other passengers again had œdematous ankles. As quite a number of the passengers on the return trip were non-English speaking, it was difficult to get percentages or details of their physical conditions. Several of the pilots whom I questioned informed me that their ankles did not become œdematous. The most likely explanation for the œdema is that in the heat of the tropics the prolonged inactivity, with dependent position of the legs, causes stasis.

I am, Sir, yours faithfully,

Johannesburg, Dec. 29th, 1935. M. WEINBREN.

INFIBULATION

To the Editor of THE LANCET

SIR,—I should like to add a little to what was written by Mr. John M. Melly in your issue of Nov. 30th, 1935, about female circumcision, under the title infibulation, which is very popular in Egypt, not less than 80 per cent. of our girls being submitted to it. No one can give a date when this habit started, but it is now so adhered to by all classes of Egyptians as to be regarded as shameful to leave a girl uncircumcised.

The operation is done usually by old women who have gained a wide experience through long practice. As Mr. Melly says, the girl is usually about the age of 7 years, but may be much older; some are circumcised just before marriage, others after they have given birth to their first child. The way in which it is done in Egypt seems to differ from that in Somaliland because here its only purpose is to lessen desire, not to create a physical obstruction to intercourse. Some, however, believe that it is a form of toilet to the external genitals. The clitoris and the labia minora are removed in one sweep of a razor, ethyl alcohol and sometimes brandy being used for asepsis before the operation and to secure hæmostasis afterwards. No stitches are applied and no anæsthetic is used. The girl's legs are not bound together and the stump of each labium heals separately. Sometimes cases are referred to hospital with severe bleeding from the dorsal artery of the clitoris, for which we ligature the stump of the clitoris; occasionally one meets with retention of urine, relieved by a hot hip bath. I have never seen any cases of sepsis. The raw surface mostly heals by first intention; if infection occurs, it must be very rare.

I am, Sir, yours faithfully,

B. GIRGIS,

House Surgeon, King Fouad 1st Children Hospital,
Jan. 3rd. Cairo, Egypt.

TESTIMONIAL TO DR. ROWLAND FOTHERGILL

To the Editor of THE LANCET

SIR,—For over 33 years Dr. E. R. Fothergill has been prominent in British Medical Association affairs, and there are few members of the Association who are better known to those who take an interest in it. First in Wandsworth, then in Brighton, he has been an indefatigable local worker. For 22 years he has been a member of the representative body, for 25 years on the council, and for 22 years a representative on the panel conference.

It is impossible in the limits of this letter to detail the extent and importance of Dr. Fothergill's voluntary services to the medical profession through the Association, but his work on the Insurance Acts Committee and on the body which preceded it, and also on the Hospitals and Medico-Political Committees stands out pre-eminently. It was he who suggested and promoted the first conference of local medical and panel committees at Brighton in 1913, which led to the adoption by these committees of the British Medical Association as the body to which they should look for central organisation and support. His fertility of ideas, his persistence, and his loyalty to principle and to the interests of the Association have justly given him a unique position in it which was recognised in 1931 by his election as a vice-president. His advocacy at all times of the dignity and the rights of the medical practitioner is well known.

In recent years he has been compelled by reasons of health to give up general practice, and this has severely strained his resources. This seems to us therefore an appropriate time to give to the members of the profession an opportunity to mark in a tangible way their appreciation of Dr. Fothergill's work, and of the sacrifices he has made in doing that work.

We hope for a prompt and generous response to this appeal, not only from individuals but from local medical and panel committees. Subscriptions should be sent to the treasurer, Fothergill Testimonial Fund, B.M.A. House, Tavistock-square, W.C.1.

We are, Sir, yours faithfully,

Jan. 13th.

THE VOLUNTARY HOSPITALS COMMISSION

THE first meeting of the new commission was held on Wednesday at the headquarters of the British Hospitals Association with Lord Sankey presiding. It will be remembered that the appointment of such a commission was resolved at the annual conference of the B.H.A., held at Leamington in June, 1935, with the instruction to consider the present position of the voluntary hospitals and to inquire whether recent legislative and social developments had made it desirable to take steps whether to promote their interests, to develop their policy, or to safeguard their future. The commission consists of the following ten members: Lord Cozens-Hardy; Alderman Miss H. Bartleet, J.P.; Sir Henry Brackenbury, M.D.; Alderman Alan Davies, J.P.; Prof. L. S. Dudgeon, F.R.C.P.; Mr. H. L. H. Hill; Colonel D. J. Mackintosh, M.B.; Miss E. M. Musson, R.R.C.; Sir Reginald Poole; Prof. A. W. Sheen, F.R.C.S. It will be seen to be of a highly representative character, including experts on nursing, accountancy, and legal procedure, besides men and women who know the technique of hospital administration inside and out and who have been in touch with problems of amalgamation and association. Lord Cozens-Hardy has already done for Liverpool hospitals what it is now proposed to do for the hospitals of the country; he found twenty different hospitals with similar interests, but with no single body authorised to speak on behalf of them all; and the matter has been put right. The problems have been well stated by Sir Charles Harris in the *Nineteenth Century and After* for May, 1935. In the general stocktaking of the position which is now necessary he instanced (1) the working relations which should exist between different units and especially the proper functions of the cottage hospital; (2) the question of modifying the time-honoured principle of unpaid visiting staffs; (3) economy in hospital administration and better team-work in general. If the voluntary principle is to hold its ground it is necessary, he said, for its adherents to demonstrate that in these as in national matters the intelligent coöperation of free men can achieve better results than bureaucracy or any form of dictatorship. The conundrum of to-day is to create voluntarily a machinery for effective combined action before it is too late; for, as Prof. W. Blair-Bell pointed out in the September issue of the same journal, the extraordinarily rapid march of State service in five years leaves no doubt of the urgency of the matter. Any person or body desiring to give evidence before the commission should communicate with the secretary, Mr. R. H. P. Orde, at 12, Grosvenor-crescent, London, S.W. 1.

IRELAND

(FROM OUR OWN CORRESPONDENT)

A "PROTECTED" MEDICAL SERVICE

IT is stated that the Ministry of Home Affairs for Northern Ireland has issued a circular to local authorities intimating that medical practitioners who in future seek positions as dispensary medical officers in Northern Ireland must be of British parentage, and must have at least five years' residential qualification in Great Britain or Northern

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—At a meeting of the Belfast and County Antrim branch of this society on Jan. 8th a unanimous resolution was passed expressing thanks to Dr. V. G. L. Fielden for his invaluable services as honorary secretary and treasurer for the past 28 years. Dr. Robert Marshall was appointed Dr. Fielden's successor, and future subscriptions should be sent to him at 9, College-gardens, Belfast.

Ireland. From the newspaper reports it is not clear whether the Minister has framed a regulation to this effect, or has merely intimated that unless his wishes are met by the local authorities he will refuse his sanction to those whom they elect. Hitherto throughout the area of the British Isles—both before and since the establishment of the Irish Free State as a dominion—the appearance of the candidate's name in the register of the appropriate area, without reference to either birth or residence, has been the only qualification required for public appointments. The establishment of a medical register for the Irish Free State did not impose any bar, since any medical man holding British qualifications can enter his

name on that register, and conversely anyone holding Irish Free State qualifications can enter his name on the register of the General Medical Council. As a matter of fact in recent years there must be very few medical men, other than those with local ties, who seek to enter the dispensary service in Northern Ireland as the service is less well paid than in the Irish Free State. It would be unfortunate if this decision were to give rise to retaliatory measures on the part of the Irish Free State. Many of the most capable officers in all branches of the public service in the Irish Free State are in fact natives of Northern Ireland, and particularly is this the case in the recently appointed public health service.

MEDICAL NEWS

Royal College of Surgeons of England

A meeting of the council of the college was held on Jan. 9th with Sir Cuthbert Wallace, the president, in the chair, at which a report was received from the board of examiners in anatomy and physiology for the fellowship stating that, at the examination held in December, 228 candidates were examined, of whom 70 were approved and 158 rejected, that the Hallett prize was awarded to Robert Sutherland Lawson, of the University of Melbourne. At the recent primary fellowship examination held in Calcutta, 54 candidates were examined, of whom 12 were approved.

It was reported that Mr. F. H. Bentley and Dr. David Slome had been elected Mackenzie-Mackinnon research fellows for one year. Mr. Hugh Lett was appointed Bradshaw lecturer for the year 1936, and Dr. George W. Corner, professor of anatomy in the University of Rochester, U.S.A., was appointed as the next Thomas Vicary lecturer. Mr. L. R. Braithwaite was elected representative of the college on the medical advisory committee of the British Health Resorts Association for one year, and Mr. Victor Bonney was re-elected representative on the Central Midwives Board.

A diploma of fellowship was granted to Kenneth Christie Eden, of University College Hospital, and the following diplomas were granted jointly with the Royal College of Physicians of London:—

Tropical Medicine and Hygiene: W. K. Cheng, Anastasio D'Souza, J. S. Gibson, Kalidas Mitra, and V. T. Vagh.

Psychological Medicine: J. L. Bates, A. J. Galbraith, J. F. Galloway, S. L. Last, S. A. MacKeith, W. H. McMenemy, K. R. Masani, J. A. Smeal, Alfred Torrie, Rosalind Vacher, and J. H. Watkin.

Laryngology and Otology: B. T. Bernstein, G. B. Ludlam, R. F. J. Martin, Narayana Srinivasan, T. G. Swinburne, and W. E. Williams.

The following hospitals were approved, with the posts specified, for the six months' surgical practice required of candidates for the final fellowship examination:

Warneford, Leamington, and South Warwickshire General Hospital, Leamington Spa (resident house surgeon till July 31st, 1937); Manchester, Victoria Memorial Jewish Hospital (resident surgical officer); Newcastle Hospital, New South Wales (resident medical officer, 1 house surgeon, surgical registrar and superintendent); Southend-on-Sea General Hospital (surgical registrar, 2 house surgeons); Sunderland Royal Infirmary (resident medical officer, 4 house surgeons); the Royal Hospital, Wolverhampton (resident assistant surgeon, surgical registrar, and 3 house surgeons).

Medical Research Scholarships

The Grocers' Company Scholarships.—To encourage original medical research the Grocers' Company offer three scholarships, each of £300 a year. The next election will be held in May, but applications should be sent to the clerk, Grocers' Hall, London, E.C.2, before the end of April.

Aldrich-Blake Travelling Scholarship.—The trustees of the Aldrich-Blake memorial fund will shortly award a travelling scholarship to a medical woman. Applications should be sent to the secretary of the trust, 8, Hunter-street, London, W.C.

Further particulars of both these awards will be found in our advertisement columns.

University of London

At University College, on Mondays from Jan. 20th to Feb. 24th, Mr. H. R. Ing, Ph.D., will lecture on chemical structure and pharmacological action, and on Tuesdays, beginning on Jan. 21st, Mr. G. P. Wells will give ten lectures on comparative physiology. All the lectures will be at 5 p.m., and no ticket is needed.

Prof. C. R. Harington, F.R.S., has been appointed acting director of the Charles Graham medical research laboratories at University College Hospital medical school, and Dr. A. M. H. Gray, chairman of the Graham Legacy committee.

International Congress of Physical Medicine

The sixth international congress of physical medicine will be held in London from May 12th to 16th. The meetings of the congress will be held under the following sections: kinesitherapy, physical education, hydrotherapy and climatotherapy, electrotherapy, actinotherapy, and radiotherapy and radium therapy. The hon. secretary of the British section is Dr. Albert Eidinow, 4, Upper Wimpole-street, London, W. 1.

London School of Hygiene

A course of lectures on public health, open to all medical practitioners, is in progress at the London School of Hygiene and Tropical Medicine, Keppel-street, W.C. At the next lecture, at 3 p.m. on Jan. 22nd, Dr. W. G. Savage will discuss bovine tuberculosis, and on Jan. 31st and Feb. 7th, at 11 a.m., Mr. H. E. Magee, D.Sc., will speak on nutrition. Other subjects in the course are venereal disease (Col. L. W. Harrison, Feb. 5th, 10th, and 12th, at 3 p.m.), infant feeding (Dr. A. G. Maitland-Jones, Feb. 14th, at 11 a.m.), food poisoning (Dr. W. G. Savage, Feb. 21st, at 11 a.m.), shell-fish (Prof. J. W. H. Eyre, March 9th, at 3 p.m.), and the marketing of fish and production of clean milk.

Royal Medical Benevolent Fund

This is the centenary year of the fund and a special appeal is being made for new subscribers to carry on the work and for donations. At a recent meeting of the committee 64 grants were voted amounting to £1329. The following particulars of a few of the cases helped indicate the kind of work undertaken.

Daughter, aged 73, of M.R.C.S. She has lived for many years in Italy lecturing and acting as guide to English visitors in Rome. Owing to the prospect of there being less work in the future she has decided to leave Italy. On her arrival in England she will have only £70 per annum to live on. Fund voted her an allowance of £36 per annum.

Daughter, aged 52, of M.R.C.S., who used to look after her mother, aged 87, who is also a beneficiary of the fund, and take paying guests; owing to a recent breakdown in health is unable to continue this work. The fund by contributing £68 (of which £26 is an allowance to the daughter) has raised the income of these two ladies to £137 per annum.

Daughter, aged 79, of a naval surgeon, maintained herself until eight years ago in the nursing profession. She then joined her sister and was able to manage till her sister's death recently. Although now living rent free this lady has only the old age pension of 10s. a week. The fund voted an allowance of £36 and will consider what further help may be needed.

Cheques should be addressed to the honorary treasurer, of the fund, 11, Chandos-street, Cavendish-square, London, W. 1.

Scottish Board of Control

Dr. Francis Sutherland has been appointed a deputy commissioner of the General Board of Control for Scotland.

National Hospital for Diseases of the Heart

A course of lectures, open to members of the medical profession, without fee, will be given at this hospital at 5.30 P.M. on Tuesdays from Feb. 4th to April 28th. The lecturers and their subjects will be announced weekly in our Medical Diary.

Conference on Social Work

The third International Conference on Social Work will be held at Bedford College, Regent's Park, London, N.W., from July 12th to 18th. The general subject of the meeting is social work and the community. Dr. René Sand, counsellor of the League of Red Cross Societies, is president of the executive board of the permanent committee, and Dr. Ralph Crowley, formerly senior medical officer of the Board of Education for England and Wales, is chairman of the advisory committee in Great Britain. The secretary-general is Mr. Alexander Farquharson, Le Play House, 35, Gordon-square, London, W.C.1.

Fellowship of Medicine and Post-Graduate Medical Association

The following courses will be given in February: in proctology at the St. Mark's Hospital (Feb. 3rd to 8th); in neurology at the West End Hospital for Nervous Diseases (Feb. 3rd to 8th); in chest diseases at the Brompton Hospital (Feb. 10th to 15th); and in gynecology at the Chelsea Hospital for Women (Feb. 10th to 22nd). A week-end course in physical medicine will take place at the St. John Clinic and Institute for Physical Medicine (Feb. 8th and 9th) and in children's diseases at the Princess Elizabeth Hospital (Feb. 22nd and 23rd). A series of lecture-demonstrations in anatomy and physiology, specially intended for F.R.C.S. (primary) candidates, will be given at the Infants Hospital at 8 P.M. on Mondays, Wednesdays, and Fridays from Feb. 24th to April 24th. For further particulars application should be made to the secretary of the fellowship, 1, Wimpole-street, London, W.1.

Births, Marriages, and Deaths**BIRTHS**

- BRIGG.—On Jan. 10th, at Chipping Norton, the wife of D. A. Brigg, M.B., B.S. Lond., of a son.
MARSHALL.—On Dec. 29th, 1935, at Sheffield, the wife of Dr. G. G. Marshall, of a son.
SHERIDAN.—On Jan. 1st, at Greenock, Scotland, the wife of Captain A. M. Sheridan, I.M.S., of a son.
WILCOX.—On Jan. 5th, at Lilongwe, Nyasaland, the wife of Dr. R. N. Wilcox, of a son.

MARRIAGES

- MORRAH—DAY.—On Jan. 9th, at All Saints', Foots Cray, Michael C. M. Morrah, only son of the late Major J. H. Morrah, The King's Own Regiment, to Catherine Day, M.B., B.S. Lond., of Sidcup, Kent.
OLIVER—MICHIE.—On Jan. 4th, at St. Andrew's, Frogmal, N.W., Surg.-Lieut. John Widdicombe Oliver, R.N., to Isabel Margaret, elder daughter of Mr. Charles E. Michie Finchley, N.
SPRIGGS—MACINTOSH.—On Jan. 14th, at St. John's Parish Church, Perth, Sir Edmund Spriggs, K.C.V.O., M.D., F.R.C.P., to Miss J. M. MacIntosh, eldest daughter of the late William MacIntosh, M.V.O., and Mrs. MacIntosh. The Old Parsonage, Dunning, Perthshire.
WILLIAMSON—GIBSON.—On Jan. 10th, at the Chapel of the Savoy, Bruce Williamson, M.D. Edin., to Margaret, only daughter of the late William Gibson and Mrs. Gibson, Egerton-terrace, S.W.

DEATHS

- BALL.—On Jan. 7th, the result of a motor accident, Dr. Norman Dyer Ball, younger son of the late James Dyer Ball, of Hong-Kong, and husband of Dr. Doris Bell Ball.
CANTI.—On Jan. 7th, at Ilampstead, Ronald George Canti, M.D. Camb., aged 52.
FISHER.—On Dec. 30th, 1935, Walter Fisher, M.R.C.S. Eng., of Kalem Hill, N. Rhodesia, for 46 years a medical missionary in Central Africa, aged 70.
MATTHEW.—On Jan. 11th, at Craigmakerran, Perthshire, Charles Geekie Matthew, M.B. Edin., Surg.-Capt. R.N. (retired).
SAUNDERS.—On Jan. 12th, at Pembroke Dock, Edward Argent Saunders, M.R.C.S. Eng., M.O.H. and school medical officer, Borough of Pembroke, aged 50.
WYLIE.—On Jan. 7th, at a nursing-home, Oxford, David Thomas Wylie, M.D. Durh., of Oxford, aged 73.

N.B.—A fee of 1s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE SERVICES**ROYAL NAVAL MEDICAL SERVICE**

Surg. Comdr. A. G. Bee to *Defiance*.
Surg. Lt.-Comdr. J. G. Holmes to *President* for course.
Surg. Lt.-Comdr. (D.) A. A. Gardner to *Drake* for R.N.B.
Surg. Lts. J. L. S. Steele-Perkins to *Victory* for R.N.B., N. S. Hepburn to *Gannet*, T. McCarthy to *Furious*, D. W. Walker to *Pembroke* for R.M. Infirmary, Deal, M. A. Rugg-Gunn to *Pembroke* for R.N. Hosp., Chatham, and T. F. Crean to *Pembroke* for R.N.B.
Surg. Lt. (D.) W. G. Finnie to *Ganges*.
Appointments as Admiralty Surgeon and Agent: Mr. J. M. Stuart, Ilford; Mr. A. S. Addison, M.C., Harrow; Mr. J. A. Edward, Barking; Mr. J. R. Buchanan, Watford; Mr. R. Vincent Howell, Bournemouth; and Mr. P. N. Grinling, Sheffield.

ROYAL ARMY MEDICAL CORPS

Major-Gen. O. L. Robinson, C.B., C.M.G., Colonel Commandant, R.A.M.C., will be Representative Colonel Commandant during 1936.
Short Service Commissions: Lts. R. H. Wheeler and J. J. C. Rainsbury to be Capt.

ARMY DENTAL CORPS

The name of Capt. O. E. Howell is as now described and not as shown in the *London Gazette* of Dec. 27th, 1935 (*vide* THE LANCET, Jan. 4th, 1936, p. 42).

TERRITORIAL ARMY

Hon. Maj.-Gen. Sir Cuthbert S. Wallace, K.C.M.G., C.B., relinquishes the appt. of Hon. Col. R.A.M.C. Units, 47th (2nd Lond.) Div.

Lt.-Col. and Bt. Col. A. R. Laurie, from Gen. List, R.A.M.C., to be Col., and is apptd. A.D.M.S., 46th (N. Midland) Div., vice Col. F. G. Lescher, M.C., vacated.
Maj. T. E. A. Carr to be Lt.-Col. and to comd. the 137th (N. Midland) Fd. Amb., vice Lt.-Col. and Bt. Col. A. R. Laurie, vacated.

Cpts. R. Pollok and H. S. Ward to be Maj.
M. K. Braybrooke to be Lt.
Supernumerary for Service with O.T.C.: Lts. L. C. Bousfield and N. Heath (empld. Univ. of Lond. Contgt. (Med. Unit), Sen. Div., O.T.C.) to be Capt.

ROYAL AIR FORCE

Squadron Leader T. J. X. Canton to No. 1 Flying Training School, Leuchars, for duty as medical officer.
Flight Lt. H. C. S. Pimblett to R.A.F. Hospital, Cranwell.
Flying Officer J. B. Wallace to No. 10 Flying Training School, Ternhill.

INDIAN MEDICAL SERVICE

Majs. to be Lt.-Cols.: C. M. Nicol and D. R. Thomas, O.B.E.
To be Lts. (on prob.): W. McN. Niblock, H. J. Gibson, P. A. Hubbard, T. P. Mulcahy, F. E. McLaughlin, and E. H. Wallace.

The undermentioned have vacated appts. in India:—
A.D.M.S.—Col. E. C. Hodgson, D.S.O., K.H.P., I.M.S.
D.A.D.P.—Capt. J. R. Dogra, M.D., I.M.S.
The undermentioned appts. have been made in India:—
A.D.M.S.—Col. R. P. Lewis, D.S.O., Brit. Serv.
D.A.D.P.—Capt. S. S. Bhatnagar, M.D., I.M.S.
Col. A. C. Amy, D.S.O., is vacating the appointment of Deputy-Director of Hygiene and Pathology at Army H.Q., and proceeds on eight months' leave from Feb. 17th.

DEATHS IN THE SERVICES

The death occurred on Jan. 11th, at Craigmakerran, Perthshire, of Surg.-Captain CHARLES GEEKIE MATTHEW, R.N., retired. He qualified M.B., C.M. Edin., 1885, and was then for a time in the P. and O. Steam Navigation Company's service at Edinburgh, later joining the Royal Navy. As surgeon of *Sparrow* he was present on August 27th, 1896, at the bombardment and capture by Rear-Admiral H. H. Rawson's squadron of the Sultan of Zanzibar's palace which had been seized by Seyyid Khaled. He became Surg.-Commander in 1905, and Surg.-Captain in 1918, after his retirement from the Service.

Sir James Purves-Stewart has been elected an honorary member of the New York Neurological Society.

Medical Diary

SOCIETIES

- ROYAL SOCIETY OF MEDICINE**, 1, Wimpole-street, W.
TUESDAY, Jan. 21st.
General Meeting of Fellows. 5.30 P.M. Ballot for Election to the Fellowship.
- WEDNESDAY**.
Comparative Medicine. 5 P.M. Dr. G. Marshall Findlay and Mr. I. A. Galloway: The Routes of Infection and Paths of Transmission of Viruses.
- THURSDAY**.
Urology. 8.30 P.M. Dr. J. Leon Jona: The Kidney, Pelvis—its Normal and Pathological Physiology (cinematograph).
- FRIDAY**.
Disease in Children. 5 P.M. (Cases at 4.30 P.M.) Dr. E. P. Poulton and Mr. T. W. Adams: Metabolism, General Nutrition, and Growth in Infancy and Childhood. Dr. W. S. C. Copeman: 1 and 2, Still's Disease Cured by Gold Injections. Mr. David Levi: 3. Additional Prolapsus Big Toes. Mr. H. J. Seddon: 4. Amyloid Disease Secondary to Bone Tuberculosis. Dr. Bernard Schlesinger and Dr. Annie Flew: 5. Arachnoidactyly. Dr. E. A. Cockayne and Dr. G. H. News: 6. Specimens from a Case of Schüller-Christian Syndrome. Dr. R. Wilson (for Dr. R. Lightwood): 7. Pityriasis.
- Epidemiology and State Medicine*. 8.15 P.M. Dr. H. J. Parish, Dr. C. O. Stallybrass, Dr. J. D. Rolleston, and Surgeon-Capt. S. F. Dudley: Use and Abuse of the Swab in Combating Diphtheria.
- Physiological Medicine*. 8.30 P.M. Dr. Douglas A. Robertson: The Cathode Ray Oscillograph Applied to Bio-electric Problems.
- EUGENICS SOCIETY**.
TUESDAY, Jan. 21st.—5.15 P.M. (the Rooms of the Linnean Society, Burlington House, Piccadilly, W.), Dr. S. Zuckerman: The Physiology of Fertility in Man and Monkey.
- MEDICO-LEGAL SOCIETY**.
THURSDAY, Jan. 23rd.—8.30 P.M. (Mansion House, 26, Portland-place, W.), Mr. J. B. Montagu: The Development in Criminal Law and Penology since 1910.
- CHELSEA CLINICAL SOCIETY**.
TUESDAY, Jan. 21st.—8.30 P.M. (Hotel Rembrandt, Thurlow-place, S.W.), Sir Harold Gillies: Plastic Surgery.
- HUNTERIAN SOCIETY**.
MONDAY, Jan. 20th.—9 P.M. (Mansion House, E.C.), Dr. Sven Ingvar: The Physical Basis of Psychoneurosis (Hunterian lecture.)
- ASSOCIATION OF INDUSTRIAL MEDICAL OFFICERS**.
FRIDAY, Jan. 24th.—5.15 P.M. (London School of Hygiene and Tropical Medicine, Keppel-street, W.C.), Air Vice-Marshal Sir David Munro: Physical Standards in Industry.
- SATURDAY**—10 A.M., Dr. T. O. Garland: The Relation between the Industrial Medical Officer and the General Practitioner.
- BRITISH PSYCHOLOGICAL SOCIETY**.
WEDNESDAY, Jan. 22nd.—8.30 P.M. (11, Chandos-street, W.), Dr. Sylvia Payne: Post-war Social Activities and Advances in Psychotherapy. (Medical Section.)
- LECTURES, ADDRESSES, DEMONSTRATIONS, &c.**
- ROYAL COLLEGE OF SURGEONS OF ENGLAND**, Lincoln's Inn-fields, W.C.
MONDAY, Jan. 20th.—5 P.M., Dr. E. W. Twining: A Radiological Study of the Third Ventricle.
- WEDNESDAY**—5 P.M., Mr. Arthur Bullcud: The Assessment of Dental Sepsis as a Factor Affecting Medical and Surgical Procedures.
- FRIDAY**—5 P.M., Mr. John Gilmour: Adolescent Deformities of the Acetabulum.
- UNIVERSITY OF LONDON**.
MONDAY, Jan. 20th.—5 P.M. (University College, Gower-street, W.C.), Mr. H. R. Ing, Ph.D.: Chemical Structure and Pharmacological Action. (First of six lectures.)
- TUESDAY**—5 P.M., Mr. G. P. Wells: Comparative Physiology. (First of ten lectures.)
- WEDNESDAY**—3 P.M. (London School of Hygiene and Tropical Medicine, Keppel-street, W.C.), Dr. W. G. Savage: Bovine Tuberculosis.
- WEST LONDON HOSPITAL POST-GRADUATE COLLEGE**, Hammersmith, W.
MONDAY, Jan. 20th.—10 A.M., skin clinic, medical wards. 11 A.M., surgical wards. 2 P.M., surgical and gynecological wards, gynecological and eye clinics.
- TUESDAY**—10 A.M., medical wards. 11 A.M., surgical wards. 2 P.M., throat clinic. 4.15 P.M., Dr. Scott Pinchin: The Development and Diagnosis of Pulmonary Tuberculosis.
- WEDNESDAY**—10 A.M., children's wards and clinic, medical wards. 2 P.M., eye clinic. 4.15 P.M., Mr. J. K. Hasler: Anaesthesia.
- THURSDAY**—10 A.M., neurological and gynecological clinics. Noon, fracture clinic. 2 P.M., eye and genitourinary clinics. 4 P.M., venereal diseases.
- FRIDAY**—10 A.M., skin clinic. Noon, lecture on treatment. 2 P.M., throat clinic.
- SATURDAY**—10 A.M., children's and surgical clinics, medical wards.
- The lectures at 4.15 P.M. are open to all medical practitioners without fee.
 Operations, medical and surgical clinics daily at 2 P.M.

- NATIONAL COUNCIL FOR MENTAL HYGIENE**.
THURSDAY, Jan. 23rd, to **SATURDAY**.—Fourth Biennial Conference on Mental Health at the Central Hall, Westminster, S.W.
- HOSPITAL FOR SICK CHILDREN**, Great Ormond-street, W.C.
WEDNESDAY, Jan. 22nd.—2 P.M., Dr. E. A. Cockayne: Pneumonia. 3 P.M., Dr. D. N. Nabarro: The Bacteriology of Acute Pulmonary Disinfectants.
 Out-patient Clinics daily at 10 A.M. and ward visits (except on Wednesday) at 2 P.M.
- LONDON SCHOOL OF DERMATOLOGY**, 5, Lisle-street, W.C.
TUESDAY, Jan. 21st.—5 P.M., Dr. R. T. Brain: Erythematous squamous Eruptions.
- THURSDAY**—5 P.M., Dr. L. Forman: Sycois.
- HOSPITAL FOR EPILEPSY AND PARALYSIS**, Maida Vale, W.
THURSDAY, Jan. 23rd.—3 P.M., Dr. Golla: Demonstration.
- ST. JOHN CLINIC**, Ranelagh-road, S.W.
FRIDAY, Jan. 24th.—4.30 P.M., Mr. A. G. Timbrell-Fisher: Manipulative Methods in Physical Medicine.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION**, 1, Wimpole-street, W.
MONDAY, Jan. 20th, to **SATURDAY**, Jan. 25th.—**ST. JOHN'S HOSPITAL**, 5, Lisle-street, W.C. Afternoon course in dermatology (open to non-members).—**NATIONAL HOSPITAL FOR DISEASES OF THE HEART**, Westminster-street, W. All-day course in cardiology (open to non-members).—**ST. PETER'S HOSPITAL**, Henrietta-street, W.C. All-day course in urology.—**NATIONAL TEMPERANCE HOSPITAL**, Hampstead-road, N.W. Tues., 8.30 P.M. Mr. C. A. Joll: Thyroid. Thurs., 8.30 P.M., Mr. R. C. Brock: Injuries to Bones.
 Courses arranged by the Fellowship are open only to members.
- LEEDS GENERAL INFIRMARY**.
TUESDAY, Jan. 21st.—3.30 P.M., Mr. Black: Ocular Complications of Some General Conditions.
- LEEDS PUBLIC DISPENSARY AND HOSPITAL**.
WEDNESDAY, Jan. 22nd.—4 P.M., Dr. H. H. Moll: Chronic Bronchitis.
- UNIVERSITY OF DURHAM**.
SUNDAY, Jan. 26th.—10.30 A.M. (Newcastle General Hospital), Mr. T. Clay: Surgical Cases of Interest.
- GLASGOW POST-GRADUATE ASSOCIATION**.
WEDNESDAY, Jan. 22nd.—4.15 P.M. (Royal Infirmary), Dr. John Henderson: Hypertension and Nephritis.

Appointments

- BLACK, J. I. MUNRO**, M.B. Durh., F.R.C.S. Eng., has been appointed Assistant Radium Officer to the Newcastle-upon-Tyne National Radium Centre.
- BLAIRLEY, J. B.**, M.B. Lond., F.R.C.S. Eng., M.C.O.G., Surgeon to Out-patients at the Chelsea Hospital for Women.
- BREWIS, E. G.**, M.D. Durh., M.R.C.P. Lond., D.P.H., Assistant Maternity and Child Welfare Medical Officer for Newcastle-upon-Tyne.
- BRIDGEMAN, G. J. O.**, M.B. Camb., F.R.C.S. Eng., Hon. Assistant Surgeon to the Western Ophthalmic Hospital, London.
- COLEMAN, S. M.**, M.R.C.S. Eng., D.P.M., Deputy Medical Superintendent of Renwell Hospital, Essex.
- EVANS, GEOFFREY**, M.D. Camb., F.R.C.P. Lond., Physician to St. Bartholomew's Hospital, London.
- KEON-COHEN, B. T.**, M.B. Melb., F.R.C.S. Eng., Resident Surgical Officer at the Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry.
- LUKE, J. C.**, M.D. Montreal, F.R.C.S. Eng., Resident Surgical Officer at the Huddersfield Royal Infirmary.
- OLIVER, L. C.**, F.R.C.S. Eng., Resident Surgical Officer and Registrar to the Bristol General Hospital.
- ROBERTS, G. J.**, M.D. Edin., D.P.H., Deputy County Medical Officer of Health and Deputy School Medical Officer for the county of Denbigh.
- SHANKS, HELENA**, M.B. Glasg., D.P.H., Assistant Medical Officer of Health (Maternity and Child Welfare) for Walsall.
- TATHAM, R. C.**, F.R.C.S. Eng., Resident Surgical Officer at the Hull Royal Infirmary.
- WILLIAMS, BRYAN**, M.D., F.R.C.S. Edin., M.C.O.G., Senior Resident Assistant Medical Officer (Obstetrical and Gynecological) at the Walton Hospital, Liverpool.
- WITHERS, A.**, M.R.C.S. Eng., D.P.H., D.M.R.E., Chief Assistant to the X Ray Diagnostic Department, St. Bartholomew's Hospital, London.
- New Queen Victoria Cottage Hospital, East Grinstead.*—The following appointments are announced:—
ROWNTREE, CECIL, M.B. Lond., F.R.C.S. Eng., Surgeon
SCOTT-BROWN, W. G., M.D. Edin., F.R.C.S. Eng., Surgeon to the Ear, Nose, and Throat Department;
GARDINER-HILL, H., M.D. Camb., F.R.C.P. Lond., Physician; and
FRANKLIN, JOHN, M.D. Camb., M.R.C.P. Lond., Dermatologist.
- Certifying Surgeons under the Factory and Workshop Acts:**
 Dr. W. A. LOCHHEAD (Bingley District, York, West Riding);
 Dr. K. M. MCCracken (Kelso District, Roxburgh);
 Dr. A. M. McMASTER (Rochdale District, Lancashire);
 Dr. S. L. SMITH (St. Annes-on-the-Sea District, Lancashire);
 and Dr. S. WILSON (Rochford District, Essex);
 Dr. ISOBEL C. ARMSTRONG (Kirkintilloch, Dumbarton);
 Dr. R. D. BRIDGER (Biggleswade, Bedford).
- Medical Referee under the Workmen's Compensation Act, 1925:**
 Dr. R. W. WILCOCKS, for the Braintree, Brentwood, Chelmsford, Colchester, Clacton and Halstead, Harwich and Maldon County Court Districts (Circuit No. 33).

NOTES, COMMENTS, AND ABSTRACTS

THE PRESENT POSITION OF
MEDICAL PSYCHOLOGY *

BY R. MACDONALD LADELL, M.B. Vict.

LATE MEDICAL OFFICER, MINISTRY OF PENSIONS NEUROLOGICAL
CLINIC, BIRMINGHAM, AND NEUROLOGIST,
HOLLYMOOR HOSPITAL

THIRTY years ago when I first read a paper on the problem of hysteria and its treatment by hypnotic suggestion, I had the feeling that it was scarcely respectable to spend time on imaginary ailments, or in such an apparently unscientific method of treatment. When Freud brought forward his theory of a dynamic unconscious and showed that the symptoms of a neurosis were the expression of a compromise between two conflicting mental trends and that they therefore had a meaning to the patient, I felt myself to be on more solid scientific ground. I still, however, had the feeling of being on the wrong side of the fence, since the acceptance of Freud's theories involved a consideration of the sex instinct both in the child and in the adult. One had to overcome one's own resistances before one could manage to look upon sex in a perfectly objective way, and those who did not succeed in this were apt to think of one as nasty-minded.

Since then the Great War, in providing an outlet for primitive hate and aggression, inevitably broke down our taboos, and sex expression both in word and deed broke through all artificial restraints, and it has been found impossible to replace Jack in his Box. Sex is universally recognised as one of the great driving forces of human nature, and one which can legitimately be studied. Then, too, the problem of the war neuroses brought medical psychology from its mystic cave into the full glare of publicity. Psychology became an important part of our national defences and could no longer be ignored. It was upsetting to those who conceived of illness as necessarily due to some organic lesion, to find that men could be blind, deaf, dumb, or paralysed, through purely mental processes; but the fact that they could be cured by purely mental processes proved that this was so. Materialistic medicine which tended to regard illness as something which could be studied in terms of somatic changes only, has never recovered from the shock. It is now realised that whatever the nature of the illness, one is not dealing with disease of the mind or the body, but that mind and body always interact, so that the mentality of the patient affects the course and symptoms of disease.

Interaction of Mind and Body

The discovery of X rays, radium, and light therapy has accustomed men's minds to the idea that matter, both organic and inorganic, can be altered by powerful agents which are normally unsuspected by our five senses. Indeed, under the analysis of the physicist, matter itself is seen to be nothing but a balance of electric forces and the distinction between organic and inorganic is being broken down. One is therefore no longer afraid of being regarded as a superstitious quack when one suggests that the mind plays a part in all disease and even that the mind may initiate disease. To do so is not to deny the germ theory of disease, but merely to draw attention from the

seed to the soil. The study of the endocrine glands has revealed to us the profound influence these have on the chemistry and metabolism of the body, and we know, moreover, that the lever they respond to is the emotional situation.

We are therefore well on the way to understanding how worry and anxiety, which mean chronic fear, may break down the natural defences of the body and provide a suitable breeding-ground for hostile micro-organisms, or possibly change the nature of the micro-organism itself from benign to hostile. What is true of overt fear and anxiety is just as true of emotional states which have been repressed into the unconscious and since such repressions mostly take place in infancy and childhood, it follows that the happy child is likely to be a healthy child and vice versa. One need not evoke the œdipus complex in order to explain the delicate child. Usually he is the product of fussy parents whose anxiety as to health is reflected in a constant series of prohibitions which not only rob the youngster of its natural spontaneity and joy of life, but fill its mind with fear which finds danger all around. We can see the adult product in the health enthusiast who is always seeking health but never finding it. He believes he is cultivating health, but it is illness which dominates his mind. Health, as a natural state of things, is unknown to him; he believes it can only be found by taking thought and running after strange doctrines. His anxiety betrays him and he falls a ready victim to illness under circumstances which would leave his care-free neighbour immune.

Responsibility of the Family Doctor

This conception of health throws the responsibility of the medical profession further and further back. The family doctor must see himself as the real medical officer of health and not simply a healer. Prevention from the beginning should be his aim, and so I contend that his training should be directed to that end, and that his status in the profession should be in the topmost notch. Early in his career the student should undergo vocational tests to find out if he has the natural abilities for such an onerous and distinguished responsibility as general practice. If not, he should be allowed to concentrate on one of the numerous specialties which are more of the nature of pure science, whilst the embryo general practitioner should be relieved of much of the exact knowledge of technique in examination and treatment which now crowd his curriculum, leaving the field clear for a study of child psychology and sociology without which he will find himself ill-equipped. To advocate that specialists should be trained from the beginning ad-hoc is not to deny my thesis that in illness it is the whole individual who must be considered and not a part. A woman's aphonia may be due to some conflict in her sex or domestic life, but if the G.P. discovers it to be due to a growth on the vocal cords the actual job of removing it is not his business. Similarly there are many other procedures in radiology, electrotherapeutics, chemistry of the blood and secretions, which it is enough for him to know of, without himself being able to carry out.

Naturally I do not propose to abolish the specialist medical psychologist, but his work would be halved and the remainder made easier if the family doctor had the knowledge required and used his authority to procure the right environmental influences for the child from the start. There are mothers who

*A paper read at the Midland Medical Society on Dec. 18th, 1935.

should never be allowed to suckle their children, since their nervous handling provokes fear at the outset. There are the fussy parents who implant dread of illness. The ultra-scientific parents whose science swallows up their common sense and makes life appear a dangerous burden; the authoritative whose "do not do this" render the child afraid of any natural form of activity; the possessive mother who sees in the child something to minister to her own ego and never lets it grow away from her. The general practitioner should be able to detect and deal with all these obvious causes of maladjustment, and he should certainly take as his province the field of sexology so as to be able to give advice to those who are married, those who intend to marry, and those who want to get married but cannot. The doctor should be consulted, too, on the selection of suitable schools and should be able to give his views for or against co-education in any given case.

Problems for the Specialist

Although by these means it would be possible to cut down the supply of ill-adjusted individuals from the source, many would still slip through the net and, at one stage or another, provide a problem for the specialist. Every practitioner should be something of a psychologist, but few have the knowledge or leisure to deal with a patient on psycho-analytic lines. Psycho-analysis is essentially a technique for overcoming mental resistances so that tendencies and conflicts which have become unconscious but which still exert an influence are made conscious. Actually the term psycho-analyst should be restricted to those who agree to adhere strictly to the methods of technique and interpretation initiated by Freud. Their numbers are very few in this country. The majority of practising psychologists whilst realising that Freud's doctrine of a dynamic unconscious with its corollary of repressions and resistances must remain the fundamental conception in dealing with neurotics, have nevertheless allowed themselves some modification of technique and interpretation based on their experiences in practice. Some of them find Jung's somewhat mystical outlook of real value. Others are content with the somewhat rough-and-ready "will to power" psychology of Adler. Some borrow freely from all schools and try to preserve an open mind. An adequate adjustment of the personality can be secured at different levels and by varying methods; but I think if one feels the need of a really scientific basis for psychological theory and practice one finds it in Freud, though, personally, I find the actual Freudian technique too restricted. Freud himself, however, does not claim to have revealed the whole truth and nothing but the truth, and many workers, both at home and abroad, are adding to and altering his structure.

The late Ian Suttie's book, published after his death, on the "Origins of Love and Hate," is an example of this kind of criticism and shows the change which has come over psycho-analytic thought. He believes that Freud's work is dominated too much by the idea of the influence of the father, owing to Freud's own unconscious trends, and that in attributing so much to the oedipus situation he has ignored the earlier need of the child to make adjustments to its mother. Since this earlier adjustment is one of reciprocity, the child needs its mother, the mother needs the child, we have here the germs of social relationship. Suttie shifts the emphasis from sensory gratification as the prime need of life to the need of feeling wanted and evoking tenderness.

In other words, he finds that there is a natural urge to social relations before the natural urge to purely sensory pleasure. It is interesting to find that Suttie's theory receives confirmation from another angle. Gerald Heard, in a recent book "The Source of Civilization," reviews the history of the evolution of men in the light of recent research, and concludes that the ancestors of man survived and evolved, not, as we used to be taught, owing to their superior aggressiveness, but to their refusal to specialise in defence and by retaining to a high degree sensitiveness and awareness. These latter qualities are what make for understanding our fellows, they imply an innate sense of at-one-ment with others; and so Heard, like Suttie, finds a social instinct at the bottom of man's activities. This changed emphasis which is beginning to show in analytic psychology does not mean, of course, that the sex life either of the child or adult is unimportant, but it regards maladjustment in this sphere as evidence of a deeper maladjustment to social life. One illustration may perhaps make my meaning clear. A man whose wife is frigid may become neurotic from that cause, but his neurosis is not due to the lack of sensual gratification which he might get from a more temperamental partner, but to the sense of guilt engendered by the fact that his need to feel at one with her is frustrated. There is more in sexual intercourse than the satisfaction of an appetite and the use of that phrase rather than coitus indicates where the difference lies.

Adjustments to Life

The psychologist then has to deal with the neurotic, and the neurotic person is one who has failed to make adequate adjustments to life in one or more of three spheres as Adler has pointed out. The three spheres are those of economics, sex, and society. Economic adjustment does not, of course, mean that a man must strive to accumulate riches but that he must in some way assume responsibility for his food and shelter. Nor does his adjustment to sex imply that he must necessarily indulge in heterosexual practices. He is at liberty to remain virgin but he must be fully aware of his natural sex needs and not attempt to repress them by substituting childish fantasy. Adjustment to society means that he must respect himself as a worth-while individual and be willing to coöperate with others.

The symptoms of a neurotic can usually be interpreted as an attempt to achieve by fantasy and on a childish level what he is unable to gain in reality. One might sum him up by saying that his attitude to life is either that of "let's pretend" or "shan't play." The main difference between the neurotic and the psychotic is that the former is aware throughout of some personality defect and wishes to be like others. The psychotic, on the other hand, has entered so thoroughly into the realm of "make believe" that he has lost touch with reality. That some psychoses have an origin in organic disease of the brain as in syphilitic lesions or are due to toxæmia from acute or chronic sepsis is, of course, undeniable, but in many cases there is a borderline where the neurotic imperceptibly merges into the psychotic. Schizophrenia or dementia præcox I believe to be a case in point. There is a progressive withdrawal of interest from people and from things which leads as we all know to absolute dementia. Yet there is an early stage of emotional unbalance where contact with reality is still complete and the patient is able to justify himself. We have been too apt in the past to think of the disease

in terms of its final results and consequently to believe that once the diagnosis is made there is nothing to be done but to tuck the patient away out of sight to await the appointed end. This attitude I believe to be too pessimistic. Early cases with which I have been associated have proved to have underlying mental conflicts similar to the neurotic, and I believe equally amenable to psychotherapy.

Unfortunately the early schizophrenic is impatient with all discipline and convention, and so creates disturbances which make it impossible to keep him in his home or to board him out with ordinary people. Sooner or later his conduct is considered so scandalous that he is hastily interned and, once he feels his freedom curtailed, he appears to give up the struggle and withdraw within himself more and more; thus following what has been believed to be his destiny. To me there is nothing more pathetic than to come across these border cases. They seem as if they were swept on by a rushing current, but seeking all the time for something to cling to which might save them. One gets a grip and the boy's relief and gratitude is obvious; then comes a relapse which possibly, in an appropriate environment, could be dealt with—and the current sweeps him on to be lost in the whirlpool. I ask myself whether it is not possible to provide the environment for these often brilliant youngsters which would enable the psychologist to keep in close touch with them whilst allowing them freedom for self-expression. The kind of thing I have in mind would be an open-air colony—a sort of perpetual camp where each could have his own hut and yet the opportunity to share in a communal life with the minimum of discipline and routine. With such an environment I believe the psychologist's work need not be in vain, and that many of these troubled souls could be won back to peace and usefulness.

Prevalence of Neurotic Illness

From what I have said of the need for the individual to make his adaptations to life it is easy to understand the prevalence of neurotic illness. Society grows increasingly complex. There is nothing left of the easy going *laissez-faire* of Victorian days. Science continually springs new marvels on us, man's power of control over natural forces grows day by day—yet there seems no meaning or purpose in anything. God seems no longer in his Heaven and all right with the world as Browning was able to believe. Everywhere there is questioning and seeking. In such a world it is very hard to retain the sense of security which should be the foundation on which to build life. Economic and social adjustments are equally difficult in this age of machinery and specialisation. The individual either feels himself to be a mere cog in the vast machine—or, worse still, he finds himself unwanted and on the scrap heap before he has settled down to his task. Sexual difficulties are increased by the fact that economic pressure tends to make marriage impossible in early youth—and nowhere is there an adequate outlet for the tremendous creative urge without which man would be no better than a brute.

Society is waking up to the fact that it is manufacturing misfits and a real attempt is being made to deal with the situation. Nursery schools and child guidance clinics are doing splendid work in providing the infant with the right environment and in readjustment. Psychology has found its way into the classroom and schools are being run on sounder lines. The juvenile criminal, too, is being given his chance

and his need for treatment and not punishment is recognised. All these are hopeful signs that society does recognise its responsibilities—but the need for such institutions is still far greater than the supply. It is splendid that so much is being done, and by providing for the children society is starting at the right end. The picture is not so good when we look to see what is being done for the adult neurotic who cannot possibly afford to pay for his treatment. I doubt whether there is even in the psychological clinic established in connexion with the Birmingham hospitals sufficient staff to permit of enough time being devoted to each case to bring about the necessary rapport between physician and patient. As far as I know the Tavistock Clinic in London is the only one which provides adequate facilities for psychotherapy on analytic lines and at the same time gives training to medical men in psychological methods. The need for the extension of such clinics is obvious. Neurotic illness accounts for a very large proportion of disability under the Health Insurance Act, but both facilities for treatment and trained psychologists are lacking. Both must be provided in the near future.

Psychology deals with human nature, but it is human nature trying to adapt itself to a certain social environment. It may be we are making the task too difficult. Looking around the world as it is to-day, we seem to be in a nursery of quarrelsome children. Can we wonder at the psychotic who takes one look at us and then retires into a world of his own rather than choosing to play a part in this? I believe that coöperation is a more integral part of human nature than aggression, which is the quality our civilisation has developed most. I believe that in the future the psychologist will be asked to take a leading part in planning a social order in which coöperation will be the keynote. Only then, I believe, will the problem of the neurotic be solved.

INCOME-TAX IN GENERAL PRACTICE

THE Paddington Medical Society were addressed by Mr. G. G. Turner on Jan. 14th on the subject of income-tax in general practice. He said that the taxation of a doctor's income differs from that of any other citizen only in the peculiar but confusing fact that practice is conducted from a private residence. The chief difficulty is to decide the proportion of personal to business expenditure, though here also it is only a matter of correctly applying the broad principles of the law. In dealing with income as opposed to expenditure the position is clearer. All profits, including the fees received from societies, panel, and public appointments, are assessed under the ordinary Schedule D "trades and professions," with which the practitioner is mainly concerned. If, however, he receives a salary for a whole-time work, he is taxed under the Schedule E relating to salaries. The doctor is entitled to select the closing date of his annual accounts, but he is taxed for his financial year ending before April 5th. If the basis of his assessment is the "cash system" the assessment is made only on the income received and expenses paid during the year, excluding all unpaid debts or credits. The better method, Mr. Turner insisted, is the "earnings system" in which all amounts earned and expenses incurred during the year are assessed whether there was actual payment or not; an adjustment is made for unpaid bills in the following year. A record of accounts is not compulsory, but it is strongly recommended that one should be kept to control the assessment, for all expenses due to the practice itself are exempt from taxation. Some doctors do not realise that among the deductions allowed from the gross profit are subscriptions to recognised societies and charities,

the fees, cost, and board of a locum tenens or assistant for sickness or holiday relief, the salaries of servants employed solely for the practice; the maintenance of equipment and repairs, decorations, and literature for the waiting-room and surgery; and the cost of professional literature. Insurance premiums can be deducted only if sick benefits are declared as income.

Expenses due both to practice and to private life are assessed in the proportions in which they apply to each; for example, the rent of the house, allowance being made if the practice is in an expensive locality or if the best room in the house has to be used for a surgery. Repairs, decorations, and depreciation have to be apportioned, also running expenses, cost of renewal and wear and tear of cars and electrical apparatus, and the wages of servants. In conclusion, Mr. Turner emphasised the desirability in the practitioner's own interest, of keeping detailed accounts and of consulting an expert accountant.

UNDESIRABLE, BUT WANTED

IF any of our readers receive a call from a man who gives his name as Captain MacDonald or Captain MacDoull, and who answers to the police description which follows, the visitor should be detained under some pretext until the police, who desire to hear about him, can be communicated with. The description furnished to us of "the captain" is detailed. He appears to be a little over 60 and stands 5 ft. 8 in. He is white-haired, baldish, and has a white waxed military moustache. He is of military bearing, has a ruddy complexion, officially described as "bloated," and when last seen was wearing a dark overcoat, a bowler hat, a bow tie, and spats. He speaks plausibly and may allude to having been at an old public school. He has obtained money from medical practitioners by claiming acquaintance with them or with a common friend, naming the friend, such conversations having led to loans. A coup of this sort he brought off in Harley-street on Dec. 17th last, in a distinctly ingenious way. "Captain MacDonald" is now wanted by the C.I. Departments of Marylebone-lane (Welbeck 2824) and Bow-street (Temple Bar 6400) police stations.

GUIDE TO LECTURES

Messrs. H. K. Lewis and Co., Ltd., are issuing with the bi-monthly list of books added to their lending library a list of lectures on medical, scientific, and technical subjects to be given in London during the same period. They believe, and we think rightly, that such a list may be of use to their subscribers. The lectures enumerated are given in the schools of London University and other places which are open to interested persons, and the list illustrates the wide range of first-hand information available to the inquiring mind. Suggestions for making the list more complete may be addressed to the compiler, Guide to Lectures, c/o Messrs. H. K. Lewis and Co., Ltd., 136, Gower-street, London, W.C.1.

Vacancies

For further information refer to the advertisement columns

Aberdeen City District Mental Hospital.—Jun. Asst. M.O. £300.
Aldrich-Blake Memorial Trust, 3, Hunter-street, W.C.—Scholarship. 200 guineas.
Ayr Royal Burgh.—M.O.H. £800.
Barry Surgical Hospital.—Res. Surg. O. £350.
Bedford County Hospital.—Second H.S. At rate of £150.
Birmingham and Midland Eye Hospital.—Res. Surg. O. £200.
Birmingham, Romsley Hill Sanatorium.—Res. Asst. M.O. £240.
Birmingham, Selly Oak Hospital.—Jun. M.O.'s. Each at rate of £200.
Blackburn, Brockhall Institution for Mental Defectives, Langho.—Jun. Asst. M.O. £500.
Bootle General Hospital.—H.P., two H.S.'s. Also Cas. O. Each at rate of £150.
Bristol Royal Infirmary.—H.P.'s, H.S.'s, &c. Each at rate of £80. Also Sen. Obstet. Surg. At rate of £100.
Carshalton, Surrey, Queen Mary's Hospital for Children.—Asst. M.O. £250.
Charing Cross Hospital, W.C.—Hon. Anesthetist.
Chelsea Hospital for Women, Arthur-street, S.W.—Pathologist. £40.
Chester Royal Infirmary.—H.P. and H.S. Each £150.
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.
Colindale Hospital, Colindale, N.W.—Asst. M.O. £350.
County Hall, Westminster Bridge, S.E.—Asst. M.O. £600.

Coventry and Warwickshire Hospital.—H.S. At rate of £125.
Croydon Mental Hospital, Upper Warlingham.—Asst. M.O. £350.
Dorset County Council.—Asst. County M.O. £500. Education Committee: Asst. Dental Officer. £450.
Eastern Fever Hospital, Homerton-grove, E.—Asst. M.O. £250.
East Ham Memorial Hospital, Shrewsbury-road, E.—H.P. At rate of £150.
Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Asst. Radiologist. £100.
Evelina Hospital for Sick Children, Southwark, S.E.—Dental Surgeon. 50 guineas.
Glasgow University.—Harry Stewart Hutchison Prize. £50.
Gloucestershire Royal Infirmary, &c.—H.S. At rate of £150.
Grimshy and District Hospital.—Sen. H.S. £200. Also Jun. H.S. and H.P. Each £150.
Grocers' Company, Grocers' Hall, E.C.—Scholarships. Each £300.
Hampstead General and N.W. London Hospital, Haaverstock Hill, N.W.—H.P. At rate of £100.
Hereford County Hospital.—Sen. H.S. £200. Also H.P. At rate of £150.
Leicester City General Hospital.—Two Res. M.O.'s. Each £300.
Liverpool and District Hospital for Diseases of Heart.—H.P. At rate of £100.
Liverpool Sanatorium, Delamere Forest, Frodsham.—Med. Sup't. £200.
L.C.C. Group Laboratory, Archway Hospital, Archway-road, N.—Asst. Pathologist. £650.
London County Council.—Asst. M.O.'s for Mental Hospital. Each £170.
London Hospital, E.—Hon. Asst. Surgeon.
London School of Clinical Medicine, Dreadnought Hospital, Greenwich, S.E.—Jun. Pathologist. £100.
Maidstone, Kent County Ophthalmic and Aural Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £200.
Manchester, Ancoats Hospital.—Two H.S.'s. Each at rate of £100. Also Med. Reg. £50.
Manchester Ear Hospital, Grosvenor-square, All Saints.—H.S. At rate of £150.
Manchester Royal Infirmary.—H.S. to Orthopaedic Dept. At rate of £50.
Middlesbrough County Borough.—Deputy M.O.H. £450.
Middlesex County Council.—Asst. M.O. £600.
Newcastle-upon-Tyne, Hospital for Sick Children.—Res. Surg. O. £250.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Jun. Surg. Reg. £150.
Oldham, Boundary Park Municipal Hospital.—Res. Asst. M.O. At rate of £200.
Oswestry, Robert Jones and Agnes Hunt Orthopaedic Hospital.—H.S. At rate of £200.
Paddington Metropolitan Borough.—Visiting M.O. 1½ guineas per attendance.
Papworth Village Settlement, Surgical Unit.—H.S. £200.
Pinewood Sanatorium, Wokingham, Berks.—Asst. M.O. £250.
Plymouth City.—Deputy M.O.H. £750.
Plymouth, Mount Gold Orthopaedic and Tuberculosis Hospital.—Asst. Res. M.O. £350.
Portsmouth Royal Hospital.—H.S. At rate of £130.
Preston, Biddulph Grange Orthopaedic Hospital.—Sen. H.S. At rate of £250.
Princess Louise Kensington Hospital for Children, St. Quintin-arcene, W.—H.P. At rate of £100.
Royal Eye Hospital, St. George's-circus, Southwark, S.E.—Hon. Asst. Surgeon.
Royal Masonic Hospital, Ravenscourt Park, W.—Surgeon.
St. John's Hospital, Lewisham, S.E.—Res. H.P. At rate of £100.
Salisbury Royal Hospital.—Orthopaedic Reg. £100.
Salisbury General Infirmary.—H.S. At rate of £125.
Smethwick, St. Chad's Hospital.—Res. Obstet. Officer. £350.
Somerser and Bath Mental Hospital, Colford, near Taunton.—Sen. Asst. M.O. £650.
South-east-Sea General Hospital.—Cas. O. At rate of £100.
Stirling District Mental Hospital, Larbert.—Jun. Asst. M.O. £300.
Stoke-on-Trent, Stannell Sanatorium.—Res. M.O. £250.
Two Res. H.P.'s. Each £125.
Westminster Hospital, Broad Sanctuary, S.W.—Asst. Obstet. Surgeon. Also House Anesthetist. At rate of £100.
Worcester County Council.—County Analyst and Bacteriologist. £800.
Worcester Royal Infirmary.—H.S. and H.P. Each at rate of £160.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at North Walsham (Norfolk), Bangor (Caernarvon), and Ruthin (Denbigh).

Corrigendum.—In the L.C.C. advertisement for Assistant Medical Officers which appeared in our advertisement columns of Jan. 11th (p. 48) the allowance of £60 to holders of D.P.M. should have been given as £50. The advertisement, as amended, is repeated in our present issue.

ASSOCIATION OF INDUSTRIAL MEDICAL OFFICERS.—The second meeting of this association will be held in the London School of Hygiene and Tropical Medicine, Keppel-street, W.C., on Friday, Jan. 24th, at 5.15 P.M., and on Saturday at 10 A.M. Discussions will be opened on physical standards in industry by Air Vice-Marshal Sir David Munro, secretary of the Industrial Health Research Board, and on the relation between the industrial medical officer and the general practitioner by Dr. T. O. Garland, medical officer of Carreras, Limited. The hon. secretary of the association is Dr. Donald Stewart, I.C.I. Metals, Ltd., Kynoch Works, Witton, Birmingham 6.

ADDRESSES AND ORIGINAL ARTICLES

CLINICAL MEDICINE

A FAREWELL LECTURE¹

BY LORD HORDER, K.C.V.O., M.D., F.R.C.P.Lond.

In place of the customary "Gentlemen" with which these lectures are prefaced I am to-day privileged to address you as "Colleagues and gentlemen." The compliment paid to me by the presence of so many of my fellow teachers is both graceful and touching. It is also, as compliments are wont to be, expensive, since the occasion which determines it costs me a great deal. Swan songs are prone to be sententious—a quality which I always try to avoid, whether in speech or in action. Personalities I dislike just as much as I dislike sententiousness. I will allow myself one brief deviation from my practice in respect of each of these two antipathies. I admit that if, after all these years, I had no sort of message for those who follow me, I should feel heartily ashamed. I also admit that this, my last clinical lecture at Bart.'s, far from leaving my withers unwrung, strains them to their utmost.

The occasion justifies a departure from custom in regard to these lectures. To-day I am not bringing before you a "difficult case," unravelling its complications as best I can, and trying to make clear the mental process by which this may be done, and thereby invite that drowsiness which, in these circumstances, tends to steal over my audience (pardonable only in the case of my house physician, for has he not already been "bored stiff" by my previous rehearsals in the ward?). Nor am I bringing a more simple case, which may be taken as a peg upon which to hang a list of causes or symptoms of disease, and thereby stimulate those who scent the possibility of something which is of potential use in another place, a stimulus which extends at times even to a little hurried note-taking (for I have never misconstrued this brief spurt of active, rather than passive, attention on the part of the less frugal minded of my audience). Instead of doing either of these things I propose to say something about clinical medicine itself—that is, about that part of the physician's work to which these lectures are a running commentary.

"TOUJOURS LES MALADES"

Whatever may be the special branch of medicine that attracts us, it is commonly accepted that it is at the bedside where, on the one hand, the vital expressions of diseases are manifested and where, on the other, the contributions made by the laboratory, both to diagnosis and to therapy, must eventually be tested. "Les malades, toujours les malades." But medicine provides such a large field for human interest and activity that there are many points at which a man may branch off into a whole life's work of relatively detached scientific effort. Any one of these digressions may take him so far away from the patient that, quite joyfully and quite successfully, he may make valuable contributions to what becomes, in effect, pure science. He may then be tempted to consider clinical medicine but a poor affair, scarcely worth the pursuit of a trained intelligence. Whereas I regard it as a very inviting field for the most highly cultivated minds—a field in which

meagre achievement, far from indicating an essential poverty in the soil that is being tilled, signifies only that the husbandman is not always as alert and well-equipped as he might be. However, what I say this morning is not intended as an apology for the clinician so much as a brief survey of his place in medicine and how his functions are, in my judgment, best performed.

In the view of some people the clinician has not advanced, or developed, proportionately with those of his colleagues who are primarily concerned with the ancillary subjects of surgical technique, bacteriology, and biochemistry. I cannot accept this estimate, and I think it is due to a false, or a forgotten, conception of the clinician's function. Though this remains what it fundamentally always was—the collection and evaluation of all available data which are pertinent to the diagnosis and the treatment of the sick person—I believe that the growth of the means by which this function is achieved has been even greater in the case of the clinician than in the case of any one of his colleagues, for the reason that the whole of their combined knowledge is available for him if he is familiar with it and cares to use it.

THREE GREAT ADVANCES

In my own time I have witnessed three great advances in the science and art of clinical medicine, and (though "I speak as a fool") these advances have seemed to me to make the clinician of much greater potential service to the patient than he was before they took place. How much he is actually of greater service depends upon himself, and the degree to which he has absorbed these advances and transmuted them into his practical work.

The function of the old clinicians was not inaptly termed "walking the wards," an expression which has its modern counterpart in "going round." Our predecessors made large observations rather than small, and they acquired a facility in diagnosis and in prognosis which seemed to many quite uncanny. This facility was really due to the fact that they had trained themselves to make a greater number of observations than they were actually aware of. Their eyes and ears and touch and smell were unaided by instruments of precision, and the pitch of excellence to which their senses perforce—and at long last—arrived was very astonishing. But their exactness stopped short at the point where their unaided senses could pierce the mystery no farther and this in many cases was stopping too short to enable them to give the help which the patient needed. For example, septicæmia was only septicæmia, and heart disease, for the most part, was only heart disease.

THE LESSONS OF THE POST-MORTEM ROOM

Then came the first great advance. With the increased frequency of, and greater thoroughness in, post-mortem examinations, the clinician began to think morbid-anatomically. This was a notable move forward. He was able to visualise the diseased organs as they actually existed during life, and this visualisation gave his clinical methods a clearer purpose and direction. This habit of correlation of the clinical features of the case with post-mortem experience remains, and must of necessity remain, one of the most valuable aids to diagnosis and prognosis. The clinician who relaxes in a punctilious attendance at the post-mortems upon his patients, or upon patients of his colleagues, thinking the time

¹ With acknowledgments to St. Bartholomew's Hospital Journal. 5365

could be better spent in the wards or in the out-patient rooms, is not only denying himself the chief correction to his exuberance and to his vanity, he is departing from the bed-rock of medicine itself. What he says at the bedside may, or may not be, the truth; what he sees in the post-mortem room is the truth. In this connexion I should like to enter a plea against too much reservation of post-mortem material for deferred examination. Some such reservation is at times desirable and even necessary, but it should be upon the decision of the pathologist and of the clinician jointly, each having regard to the claims of the other. Be it remembered that diseased organs that are opened at the time of the post-mortem examination, and are seen in relation to the rest of the body, nearly always throw light upon the obscurity that has perhaps been in the minds of those who have seen the "case" during life. Whereas organs that are dissected by the aid of the pathologist's midnight oil may, or may not, illumine his own individual darkness.

LABORATORY METHODS

The second advance came with the development of laboratory methods, since in these the clinician found new and invaluable aids to his work. The study of the patient *qua* patient was supplemented by the study of materials derived from the patient. Thus we saw the birth of clinical pathology. The past 30 years have witnessed this lusty babe grow up to a vigorous manhood. As is wont with the virile adolescent, there have been times when he thought himself more important than he really was, when he sought to bestride the whole world of medical knowledge, when he firmly believed he *was* medicine rather than merely making his contribution to medicine. His incursion into the sick room was apt to be somewhat brusque, not to say at times truculent. Cuckoo-like, he jostled and pushed and oft-times succeeded in ousting his more timid and gentle colleague from the latter's legitimate sphere. He took to describing himself in the telephone directory as "physician," and he invited the credulous sick to consult him. The public, with its child-like confidence in machinery, loved him, welcoming his advent as signalling the millennium of exact medicine, and unaware that the human brain is the best machine of all. A catalogue of the flora of the fauces and/or of the fæces, a complete blood count, a chemical analysis of the urine to the third place of decimals: "What further may be sought for or declared?" Not only was the new gospel about to dispel the darkness that shrouded diagnosis, it was about to illumine the therapeutic field also. The "opsonic index" for an exact diagnosis, the hypodermic syringe, charged with the appropriate antigen, for effective treatment, and medicine was "taped" at last. The clinician came to be regarded by some with amused tolerance; by others, even less generously minded, as obstructive to real progress. Nosology disappeared and pathology contracted down to the name of the infecting agent; patients no longer suffered from diseases but from micro-organisms. "What is the matter with the man in bed 4?" "T.B. . . ."

But fortunately for the patient, for whom, like the soul of Faustus, the powers of good and evil were fighting, some clinicians kept their heads. They absorbed what was good in these clinico-pathological advances, seeing in them important supplemental aids to their methods rather than a substitution for them. But the older and cruder notions of infection had to be entirely revised; and

gaps in the knowledge of metabolism had to be filled. Not only was it necessary that the clinician should think morbid-anatomically, it was necessary that he should think bacteriologically and bio-chemically also.

RÖNTGENOLOGY

Then came the third great advance, and by means of an entirely new tool. I refer to the arrival of roentgenology. Though useful from the first, it has taken a good many years to improve the technique and to get the method under control, but to-day there is probably no more useful addition to the clinician's methods. The exercise of forbearance in interpretation on the diagnostic side, and of moderation in claims on the therapeutic side, have become an important part of the clinician's work.

ESSENTIAL DATA

I said just now that the fundamental function of the clinician is to collect and to evaluate data. But what data? The clinician is not a *mere* collector of data. If he were, diagnosis would be as easy for one man as for another. Nor is he a mere recorder of cases seen. If he were, the palm would go to the panel practitioner or to the junior casualty physician, though this consideration waives a fact of which we are well aware—that it is possible, nay easy, to see a great number of patients and yet not see their diseases. It is the *essential* data that we want, not the unessential. It is data that are associated, not data that are dissociated. The capacity to neglect is as important as the capacity to take notice. True, the more obscure the case the less we can afford, in the first survey, to omit any examination; but after a time there comes what may seem to some an almost astounding negligence. This is not forgetfulness, nor a lapse from good methods; *it is the ability safely to omit*. Patients' dossiers are apt, in these days, to be so full and so heterogeneous that the courage to say of some of the reports, "noted, nothing doing," is often the first step in the elucidation of the problem. It falls to the clinician alone to become familiar with the range of health, to be sensitive to what lies within it, and to what lies outside it. The exercise of this sensitiveness in any particular case becomes more and more essential the more meticulously exact the reports of the experts may be. And these reports tend to be more and more meticulously exact with the increasing tendency to specialism and the myopia which goes with it. The number of patients whose hearts are healthy is in inverse proportion to the number of cardiologists they consult, and the frequency with which they are "electrocardiographed." An upper respiratory tract which is passed as "normal" by a careful "nose and throat man" will soon be so rare as to merit demonstration at the Royal Society of Medicine.

BEDSIDE OBSERVATIONS

It has been during the recent period of intensive laboratory investigations on the clinico-pathological side of diagnosis that the notion has arisen that the clinician's observations are not really scientific, that they are of the nature of guess-work, whereas everything that happens in the laboratory is controlled by the infallible rules of logic. The test-tube and the microscope cannot lie. But God alone knows if what the physician thinks is an enlarged spleen is the spleen; or if rose spots are not "any old spots"; or the association of a soft and infrequent pulse with a continued high fever is not some odd trick of Nature designed to intrigue the curious-minded; and why

should not a week of intense headache pass away somewhat suddenly and be replaced by a muttering delirium; and an unexplained deafness appear? Funny things like these do happen to people who suffer from a disease of microbic origin. But the one certain thing is that the disease isn't typhoid fever, or any infection in the T.A.B. group, because there is no agglutination of the laboratory stains of those organisms by the patient's serum. Strange, this idea that facts have a different value according as they are observed at the bedside or in the laboratory. Stranger still, the idea that one negative observation in the laboratory should, by responsible clinicians, be regarded as more important than six positive observations at the bedside. "We can never, by a single experiment, prove the non-existence of a supposed effect." If "science arises from the discovery of identity amidst diversity" then it matters not if the identity be discovered by careful observation of the patient clinically or pathologically. The whole question is, is it a *true* identity? But this, in the last resort, depends upon the critical judgment of the observer. Granted that the exercise of judgment at the bedside is more difficult than it is in the laboratory, mistakes in judgment are not confined to the bedside. We have only to send a specimen of the same stool to two, or even to six, bacteriologists, equally expert, to find that failure to "discover identity" is by no means only a bedside difficulty. Here the question of criteria is involved, as we know, and criteria are not always uniform even amongst laboratory workers. Their results are therefore, of necessity, not always comparable. Now the clinician's criteria are, in general, less exact than the pathologist's, nor can they be made so exact very easily; but if they are made severe, as they should be—if nothing is termed positive which is only doubtfully positive; if the clinician's judgment concerning his observations is controlled by reliable technique; if discovered identities are unequivocal—then his "facts" are as scientific and as logical as are those of the pathologist. The truth is that clear thinking, with forbearance, is essential to the satisfactory solution of a diagnostic problem whether the contribution comes from the laboratory or from the bedside.

MENTAL TECHNIQUE

There is a technique of the mind as well as of the eye and of the hand, and the former is quite as essential as the latter. It is not only what you find at the bedside, it is also what you bring to the bedside. The eye sees what it takes with it the power of seeing: it is the *mind* that sees. And surely it is the same in the laboratory? In both spheres there comes to some—slowly, painfully, towards the end (alas!)—facility born by patient practice out of time. Clinician and pathologist are more akin than they sometimes realise. Each of them takes a pride (which the other regards as excessive) in his small discoveries, and each of them lacks humility (or so the other thinks) in face of the certain fact that every day, whether it be in the ward or in the laboratory, momentous things are happening under their very eyes, yet they see them not, for they are both under the same ban—they cannot live out of their generation.

CLINICAL RESEARCH

If, looking back, I can feel satisfaction with any modest effort of my own in the diagnostic field, it is in opposing the tendency of the past two decades towards the divorce of clinical from laboratory methods. In this hospital this divorce has really never occurred. Kanthack and Andrewes and Gordon

and Kettle and Canti have been too wise not to see that pathological processes have a unity which centres itself in the patient and that without careful study at the bedside only one part of these processes can be elucidated. It is the close coöperation of both observers, and this alone, that can lead to results that are helpful. We at Bart.'s have been fortunate in this matter, and I hasten to add that any mild strictures of mine refer not to our school, but to a part of the greater world of medicine outside.

But clinical medicine in this greater world is just now coming back into its own. The prince has taken notice of the neglected charms of our modest Cinderella. A marriage is being arranged. Professors are leading her to the altar, and the name of her bridegroom is Research. There is just time for me, as an interested and loving uncle, to give the pair my blessing.

"Let me not to the marriage of true minds
Admit impediments. Love is not love
Which alters when it alteration finds,
Or bends with the remover to remove:
O, no! it is an ever fixed mark
That looks on tempests and is never shaken;
It is the star to every wandering bark,
Whose worth's unknown, although his height be taken."

And so is resumed afresh the long line of clinical observers which has been lit by the genius of Hippocrates, of Sydenham, of Trousseau, of Osler, and of many others—masters in clinical research.

CLINICAL TEACHING

A few words about clinical teaching before I close. Time has not led me to change my view that the best help the clinician can give his pupils during the early part of their career is to insist that they use their words carefully, exactly, and without ambiguity. Next to this, but only by means of this, he can help them to think clearly. This is important, too, for as Thomas Hobbes said "as men abound in copiousness of language; so they become more wise, or more mad than ordinary." I may be forgiven for repeating myself and saying that the first text-book of medicine should be Jevons' "Primer of Logic." It costs one shilling but is worth untold gold. Note-taking must never be scamped. What is written about the facts of a case demands the same care as what is said about them. If to these things can be added a thorough drilling in methods of clinical examination we have really accomplished a great deal in the first three months. Be it never forgotten that to watch the teacher's own methods is of greater help in the earlier stages of clerking than to try to understand what he is talking about. Efforts to teach medicine, however tempting, should be resisted. The keen student will teach himself medicine if he is properly trained in these important preliminaries.

THE CURRICULUM

I wish something could be done to save the clerk's valuable time in the wards by introducing into the pre-clinical studies a number of examinations and methods which have really to do with anatomy and physiology. I have often dealt with this matter, but I make no excuse for referring to it again. The fundus oculi and the membrana tympani are normal anatomical structures, yet few clinical clerks have ever seen them before they enter the wards and, largely as the result of this fact, some have not seen them clearly even when they leave. We could profitably exchange the time spent over theories of colour vision and the intimate structure of the organ of Corti for these important matters. The blood-cells are a part of normal histology but they have rarely been counted, or, if they have, it has only been during the

demonstration of the Thoma-Zeiss pipette. The contours of the abdomen, the reflexes and tendon-jerks, the normal gait, the surface markings of the lungs, the deposits that may occur in urine apart from disease, the flora of the fæces in health . . . is it really economical that the time of the clinicians—and of the senior clinicians—should be taken up in teaching about these things? Mr. Dean, we have praised you, though not more than you deserve, on account of the magnificent laboratories and equipment which you have assembled on the Merchant Taylors' site. Here is another piece of work for you and your colleagues—this adjustment of the pre-clinical studies so that they conform more to the requirements of men who are going to be doctors, and valuable time may be saved for the later years of the curriculum.

VALE

Well, I must bid you good-bye. It has all been, in schoolboy phraseology, "great fun" and I have thoroughly enjoyed it. The clinician's material has not been confined to the patients in their beds. For there have been the clerks themselves . . . and the rest of the "firm" . . . and the nursing staff . . . and the porters whistling outside the ward, under the echoing shaft of the lift . . . and the buzzer that calls for the anaesthetist who is never there . . . and this lecture theatre. More than all this, there has been the world outside—the domestic circle, the market place, the forum. There has been the whole human comedy as seen by Shakespeare and Molière and Cervantes and the other great clinical observers. I hope I have not put too many of you, whom I have been privileged to teach, out of your stride. I trust my methods, and my teaching, have conformed in some measure to the great traditions of this place. But they have been largely, and of necessity, myself:

"ay, there's the rub."

So now I doff my ward coat and hand it to you, Evans, my friend. Gow and you have been loyal, inspiring, and very charitable colleagues, and I tender you my most sincere thanks. God bless you, and God help you!

EXOPHTHALMOS

FOLLOWING THE ADMINISTRATION OF THYROID EXTRACT *

By W. RUSSELL BRAIN, D.M. Oxon., F.R.C.P. Lond.

PHYSICIAN WITH CHARGE OF OUT-PATIENTS TO THE LONDON HOSPITAL; PHYSICIAN TO THE ROYAL LONDON OPHTHALMIC HOSPITAL AND THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE

ONE of the most puzzling of the many problems arising out of the state of thyrotoxicosis is the mode of production of exophthalmos. There is at present no satisfactory explanation either of the nature of the changes in the orbit which lead to exophthalmos, nor of the way in which these changes are associated with thyrotoxicosis. The difficulty of explaining the exophthalmos is enhanced by the fact, which is generally admitted, that the administration of thyroxine or of thyroid extract, whether experimentally to animals or therapeutically to man, does not as a rule lead to exophthalmos. The rarity of this event in man may be gauged from the fact that not more than about twenty instances have been reported. The development of progressive exoph-

thalmos in patients who have previously undergone subtotal thyroidectomy for thyrotoxicosis is a closely related phenomenon, since this may be precipitated by the administration of thyroid extract to correct post-operative hypothyroidism. The object of this paper is to report a new case of exophthalmos following the administration of thyroid extract. The significance of this sequence of events is discussed in the light of this and previously reported cases and of recent experimental work on exophthalmos.

AUTHOR'S CASE

An unmarried Hebrew woman, aged 38, was referred to me from Sir Stewart Duke-Elder's clinic at the Royal London Ophthalmic Hospital on May 14th, 1934. Since the age of 5 she had suffered from epileptic fits, which were mainly nocturnal, and occurred almost every night during her sleep, though in addition she used to have one or two every week during the day. Her menstrual history was normal.

In October, 1923, in addition to bromide and iodide she was given thyroid tablets, grs. 2, twice a day for three months. In 1926 she had a further course of thyroid extract for three months and again in 1928. In 1929 she again took thyroid extract until February, 1930. In October, 1930, she started to take $\frac{1}{2}$ grain of thyroid extract, and then 1 grain, twice daily, and had taken the thyroid almost continuously ever since. During the whole of this period she had been taking bromides almost constantly and occasionally Luminal. During the three and a half years before she came under observation she must have taken approximately 2000 grains of thyroid extract.

In the middle of April, 1934, the left eye was first noticed to be prominent. When she first attended the Royal London Ophthalmic Hospital her condition was as follows. Of somewhat retarded mental development. Rather obese. Weight 11 st. 6 lb. (Average weight 8 st. 10 lb.) Height 4 ft. 11 $\frac{1}{2}$ in. Thick, dark hair on scalp. Heavy eyebrows. Growth of hair on lips and chin, shaved. Thyroid not visibly or palpably enlarged. Pulse regular, rate varying between 90 and 104. Blood pressure 135/80. Fine tremor of hands. The left eye protruded 4 to 5 mm. in front of the right and the left upper lid was retracted. No orbital irregularity was discovered. The ocular fundi were normal and visual acuity was 6/6 in both eyes. Central nervous system, heart, lungs, and abdomen were normal. The urine contained a trace of albumin and no sugar.

The administration of thyroid extract was at once suspended. By July 23rd the patient's pulse-rate had dropped to from 80 to 84. The state of her eye at this time is shown in Figs. 1 and 2.

She was admitted to the London Hospital on Oct. 4th, 1934 (No. 41578). The exophthalmos had now diminished considerably (Figs. 3 and 4) and her weight was 11 st. 12 $\frac{1}{2}$ lb. Radiograms of the skull showed no abnormality. Her basal metabolic rate on Oct. 19th was plus 9.2 per cent. and on Oct. 21st plus 4 per cent. Her blood Wassermann reaction was negative. While in hospital she had six epileptic fits. She was discharged from hospital on Oct. 23rd, 1934, and has since been under observation as an out-patient. The exophthalmos steadily diminished (Figs. 5 and 6) until in April, 1935, the left eye was only 1 mm. in front of the right. The difference in November, 1935, was scarcely perceptible (Figs. 7 and 8). After the withdrawal of the thyroid extract her weight steadily increased until in May, 1935, it was 12 st. 8 lb., since when she has been on a reducing diet. Her epileptic fits have responded well to luminal and bromide, but she still has an attack occasionally.

In this patient, therefore, the unilateral exophthalmos, which followed the prolonged but intermittent administration of thyroid extract, subsided almost completely within a year of the withdrawal of thyroid. It is noteworthy that the patient showed signs of endocrine abnormality—namely, obesity and excessive hairiness.

* From the neurological department of the London Hospital, and the Royal London Ophthalmic Hospital.

FIGS. 1 and 2.—The patient on July 25th, 1934.

FIGS. 3 and 4.—Oct. 22nd, 1934.

PREVIOUSLY REPORTED CASES

Béclère's Case (1894).¹—Female, aged 34. Had been treated for myxœdema by means of thyroid gland. By mistake she took 92 grammes of thyroid gland in eleven days. After this she developed exophthalmos and a staring expression, tremor of the arms, tachycardia, instability of pulse, elevation of the temperature, insomnia, agitation, polyuria, glycosuria, albuminuria, and paraplegia. The paraplegia, in view of a history of previous hysterical symptoms, was regarded as hysterical.

von Nothhafft's Case (1894).²⁴—Male, aged 43. Suffered from increasing obesity and treated himself with thyroid. Within about five weeks he took nearly a thousand tablets of 0.3 gramme Burroughs Wellcome's thyroid preparation. During the five weeks he lost 28 lb. in weight, from 220 lb. to 192 lb. During the third week he began to develop symptoms. At the end of five weeks he showed moderate exophthalmos, with lid lag. His face was flushed and the whole skin moist. There was a gross tremor, most severe in the hands. The pulse-rate was 120. The thyroid was not visibly or palpably enlarged.

Lawford's Case (1900).¹⁰—Female, aged 34. Had suffered from myxœdema for five years. Thyroid extract administered, dose not stated. As she benefited greatly, the treatment was interrupted but was resumed 4½ years later. After one week the eyes became prominent and the exophthalmos steadily increased. She did not complain of palpitation and was not emotional. The thyroid gland was scarcely felt, so was not enlarged.

Ulrich's Case (1900).²⁵—Female, aged 46. Had suffered from myxœdema for ten years. On thyroid treatment (0.05 x 2) there was rapid improvement and her hair grew again, but she developed exophthalmos, tachycardia, excessive sweating, and progressive wasting, resembling a patient with Basedow's disease.

Stegmann's Case (1906).²⁴—Female, aged 14. Had suffered from her fourth year from slight swelling of the neck, which gradually increased in size. She was given

1½ Thyroidin tablets per day. She rapidly developed severe palpitations and the treatment was discontinued. There was, however, only temporary improvement and three months after taking the thyroid she began to suffer from palpitations and, a month later, protrusion of the eyes began to develop. Eight months after the beginning of the treatment her weight had fallen from 64 to 46.7 kg. She exhibited gross exophthalmos and a diffuse, soft, visibly pulsating enlargement of the thyroid, very severe tremor, and a pulse which was very irregular and lay between 130 and 150 in rate. The heart was slightly enlarged. Her general condition improved greatly following X ray irradiation of the thyroid.

Pulawski's Case (1912).²¹—Female, aged 47. Had had a goitre for 18 years. As it began to increase in size she was ordered to take thyroidin. During four weeks she took 38 tablets (Poehl). She began to lose weight and suffered from palpitations. Four months after beginning to take the thyroid she had slight exophthalmos and Stellwag's sign was positive. She was emaciated and nervous and tremulous, with a pulse-rate of 120. The goitre was firm but did not pulsate. The patient refused operation but improved slightly on medical treatment.

Holböll's Case (1927).⁵—Female, aged 46. Increased steadily in weight after the menopause. For 50 days she took thyroid gland tablets (Medix, strength No. 4, 1 tablet a day). She began to suffer from nervousness, tremor, and palpitation and, later, exophthalmos, sweating, and enlargement of the thyroid developed. The loss of weight was progressive. Four months after beginning to take the thyroid extract the typical picture of exophthalmic goitre was present. The pulse-rate ranged between 100 and 140. The basal metabolic rate was 157 per cent. She became delirious and died one month later. There was no autopsy.

H. U. Møller's Case (1928).¹⁶—Female, aged 49. Had been taking thyroid preparation for seven years. She developed unilateral exophthalmos, for which no local

FIGS. 5 and 6.—Dec. 31st, 1934.

FIGS. 7 and 8.—Nov. 28th, 1935.

cause could be found on ophthalmological and X ray examination. She also showed tachycardia, tremor, goitre, glycosuria, fasting hyperglycæmia (0.137 per cent.). The thyroid administration was discontinued. Six months later the goitre and exophthalmos persisted but the pulse-rate was normal. The diabetes proved to be of a very benign character.

*E. Møller's Case 1 (1930).*¹⁵—Female, aged 49. Artificial menopause induced four years previously with X rays, owing to uterine fibroids. After this there was some increase in weight and she began to take thyroid extract. In the course of six weeks she took between 110 and 120 thyroid gland tablets (Medix, strength No. 1, three tablets a day). She developed nervousness, insomnia, tremor, palpitation, dyspnœa, diarrhœa, profuse sweating, thirst, and faintness. Goitre appeared and exophthalmos was noted. She lost 21 kg. in weight during three months. The basal metabolic rate was 152 per cent. and the patient was regarded as a typical example of severe thyrotoxic goitre. She became delirious and later comatose and died seven months after beginning to take the thyroid.

Post-mortem examination. The thyroid gland was enlarged, without cysts or hæmorrhages. Microscopically, the follicles were of very unequal size. The epithelium was flat, cubical, or cylindrical. In most follicles papillomatous excrescences were found consisting of thin septa of fibrous tissue covered with flat or cubical epithelial cells. No colloid was found anywhere and there was no leucocytic or lymphocytic infiltration. Vascularisation was normal. The brain, cerebellum, and medulla oblongata were microscopically normal and sections from the cerebral cortex, optic thalamus and caudate nucleus, cerebellum, and from the borderline between the pons and medulla were all normal, except for a mild degree of hyperæmia.

*E. Møller's Case 2 (1930).*¹⁶—Male, aged 49. Developed myxœdema in 1913. From 1916 until 1924 thyroid extract was given in an average dose of 4 centigrammes daily. This removed all the symptoms and the patient was very well and able to work. In 1924, without any discoverable cause, palpitation, nervousness, feeling of heat, increased sweating, and tremor of the hands developed. The pulse-rate rose to about 90 and slight exophthalmos was noted. At the beginning of 1930 there was glycosuria. At this time there was bilateral exophthalmos with slight œdema of the eyelids and weakness of ocular convergence. Pulse-rate ranged between 90 and 100. There was slight rapid tremor of the hands. The thyroid was not markedly palpable. The urine was normal, except for an occasional, slight alimentary glycosuria. The blood-sugar was normal. The patient was nervous and restless. The basal metabolic rate was plus 78 per cent. The exophthalmometer measured: right 25 mm., left 24 mm.

*Moorhead's Case (1931).*¹⁸—Female, aged 54. In 1924 was considered to be suffering from myxœdema and thyroid extract was prescribed, with much benefit. At the beginning of 1926 the dose of thyroid extract was increased to grs. 12½ daily and this dose was taken continuously throughout that year. Early in 1927 it was noted that her right eye was much more prominent than her left. At this time the right eye was extremely prominent and showed well-marked von Graefe's sign, while the left appeared normal. The patient was extremely nervous and restless and suffered from insomnia and loss of weight. The pulse was rapid, the rate being 140. The thyroid gland could not be felt. The administration of thyroid extract was stopped and the patient was put to bed and treated with bromides. In two months the symptoms had largely disappeared and after six months the patient was practically well. As the general symptoms subsided the exophthalmos diminished but 18 months after the onset of hyperthyroidism the right eye was still somewhat more prominent than the left.

*Hurxthal's Cases (1931).*⁶—Hurxthal states that he was able to find 40 cases in which there seemed to be a history of dieting or the use of thyroid extract in patients suffering from exophthalmic goitre. Of this number, however, only 9 could be selected in which it was felt that there was no question as to the onset of exophthalmic goitre following one or other of these procedures. Of these 9 patients 7 had taken thyroid extract.

Hurxthal's Case 1.—Female, aged 33. In order to reduce weight took an unknown dose of thyroid extract for one year. Her weight fell from 180 to 130 lb. She developed typical exophthalmic goitre, with pulse of 92, basal metabolic rate plus 36. Subtotal thyroidectomy was performed and one year later weight was 162 lb., pulse-rate 68, basal metabolic rate plus 20.

Hurxthal's Case 2.—Female, aged 51. Took 1 grain of thyroid extract daily for six months. Weight fell from 164 to 139 lb. She developed exophthalmic goitre. Pulse-rate was 76, basal metabolic rate (after Lugol's solution) plus 19. Subtotal thyroidectomy was performed. One year later pulse-rate was 68, weight 146 lb., basal metabolic rate minus 6.

Hurxthal's Case 3.—Female, aged 43. Took an unknown dose of thyroid extract for five months, in order to reduce weight. Weight fell from 162 to 131 lb. She developed a swelling of the neck and presented a picture of typical exophthalmic goitre with pulse-rate of 108 and basal metabolic rate plus 45. Subtotal thyroidectomy was performed and later the weight was 138 lb., pulse-rate 78, and the basal metabolic rate minus 12.

Hurxthal's Case 4.—Female, aged 38. Took thyroid extract in unknown dosage for three months. Weight fell from 165 to 135 lb. She developed typical exophthalmic goitre, with pulse-rate of 118, basal metabolic rate plus 18. Subtotal thyroidectomy was performed. Basal metabolic rate one year later was plus 5, pulse-rate 92, weight 145 lb.

Hurxthal's Case 5.—Female, aged 19. For two months took one tablet of thyroid extract three times a day in order to reduce weight. Weight fell from 180 to 165 lb. She developed a typical exophthalmic goitre, with marked exophthalmos, a large hyperplastic thyroid gland; the basal metabolic rate was plus 19, the pulse-rate 104. Subtotal thyroidectomy was performed. Six months later pulse-rate was 58, weight 187½ lb. and the basal metabolic rate minus 1.

Hurxthal's Case 6.—Female, aged 55. Took 2 grains of thyroid extract three times a day for seven months and lost weight from 191½ to 158½ lb. This patient developed the typical picture of toxic adenoma of the thyroid with a small firm gland, containing small adenoma and no exophthalmos. Her basal metabolic rate was plus 36, her pulse-rate 106.

Hurxthal's Case 7.—Female, aged 54. In order to reduce weight first took a restricted diet for six months. She lost 20 lb. and was then given thyroid extract for about six months. Six months after stopping the thyroid extract she presented the picture of severe exophthalmic goitre, with congestive heart failure and auricular fibrillation. Her weight was 142 lb., her pulse-rate 116, and her basal metabolic rate plus 58. Subtotal thyroidectomy was performed in two stages and one year later her weight was 148½ lb., her pulse-rate 96 and regular, and her basal metabolic rate minus 1.

It will be seen that exophthalmos is specifically mentioned as being present in only 1 of Hurxthal's 7 cases. It is noted as having been absent in 1 case and in the 5 remaining cases the condition was said to be one of exophthalmic goitre or typical exophthalmic goitre. It may reasonably be presumed that exophthalmos was present in these cases also. Hurxthal states that with the exception of one patient, who was not operated on, the typical pathological picture of hyperplasia of the thyroid was found, the glands being in all cases enlarged clinically and diffusely hyperplastic.

In the 19 reported cases thyroid extract was taken for obesity in 10, for myxœdema in 6, for goitre in 2, and for epilepsy in 1. In most cases the administration of thyroid extract appears to have initiated a condition closely resembling if not identical with exophthalmic goitre, which persisted or grew worse after withdrawal of the thyroid extract. In one case, E. Møller's Case 1, it proved fatal; in Hurxthal's cases it was treated by subtotal thyroidectomy, and

in Stegmann's case it was relieved by X ray irradiation of the thyroid. Pathological changes in the fatal case and in Hurxthal's cases appear to have been those of typical exophthalmic goitre. In 2 cases no mention is made of enlargement of the thyroid, and in 2 other cases there was a goitre before thyroid extract was administered. In the remaining cases the thyroid became enlarged in 10, while no enlargement was noticed in 5. In 2 cases in which the thyroid was not found to be enlarged, Moorhead's case and my case, the condition differed from typical exophthalmic goitre in that the patient began to improve as soon as the thyroid extract was withdrawn and made a recovery which was complete except for very slight residual exophthalmos. In 3 of the 19 cases the exophthalmos was noted as unilateral.

RÔLE OF THYROXINE IN THE PRODUCTION OF EXOPHTHALMOS

Since a very large number of persons take thyroid extract for long periods, some even in excessive doses, without developing exophthalmos, and since thyroxine fails to produce exophthalmos when given experimentally to normal animals, it seems probable that some other factor than the ingestion of thyroid extract or thyroxine is necessary in order that exophthalmos may develop. Recent experimental work yields some support for this view. Justin-Besançon, Kohler, Schiff-Wertheimer, and Soulié,⁷ working with dogs, have found it possible to produce exophthalmos by means of various drugs which stimulate the sympathetic nervous system. These workers have shown that such drugs differ from one another in their relative influence upon the eye and upon other structures innervated by the sympathetic. Thus the least doses of substances of the adrenaline group which had a powerful vasoconstrictor effect led to only a feeble exophthalmos. On the other hand, other sympathomimetic drugs, such as ephedrine or ephedrone, caused a very marked exophthalmos in doses which produced a rise of blood pressure equal to, or even less than, those obtained with adrenaline. Other drugs, such as tyramine, phenylethylamine and paramethylethylamine, fell between these two groups in their relative influence on the arterial pressure and on protrusion of the eyeballs. The same workers were unable to produce exophthalmos in dogs by means of thyroxine, even when given in large and repeated doses sufficient to cause rapid emaciation and a marked tachycardia. They found, however, that thyroxine appeared to sensitise the eye to sympathomimetic drugs, and that when thyroxine was given either before or after the administration of such a drug it was possible to produce exophthalmos by means of a dose of a sympathomimetic drug previously inadequate to do so or to obtain a much greater degree of exophthalmos than could be evoked by the sympathomimetic drug alone. Labbé, Villaret, Justin-Besançon, and Soulié⁹ have investigated this synergic effect of thyroxine upon sympathomimetic drugs in a patient who, in order to reduce her weight, took 10 mg. of thyroxine daily by the mouth. The patient soon presented signs of hyperthyroidism: severe and rapid emaciation, tachycardia, insomnia, and rise of basal metabolic rate, but at no time was there exophthalmos. They were able to produce a transitory exophthalmos, however, by giving to this patient on one occasion ephedrine and on another occasion ephedrone in combination with thyroxine. The same workers claim to have produced exophthalmos in a patient suffering from spontaneous hyperthyroidism but

without showing this symptom by the administration of ephedrine, and they quote an observation of Sainton²² on a myxedematous patient who developed exophthalmos when treated with thyroxine and adrenaline in combination.

These observations suggest that thyroxine while unable to produce exophthalmos alone can do so in combination with a substance capable of stimulating the sympathetic.

RÔLE OF THE THYROTROPIC HORMONE OF THE PITUITARY IN THE PRODUCTION OF EXOPHTHALMOS

The discovery of the thyrotropic hormone of the pituitary has opened a new road of approach to the problem of the pathogenesis of exophthalmos. Marine and his collaborators¹¹⁻¹⁴ in a series of experiments first found that bilateral exophthalmos could be produced in rabbits maintained on a diet of alfalfa hay and oats by means of the daily intramuscular injection of methyl cyanide. In such animals the exophthalmos was associated with thyroid hyperplasia, but the same workers found that exophthalmos was more easily produced and more marked in rabbits from which the thyroid had been removed. They next succeeded in producing exophthalmos in guinea-pigs by means of the administration of the thyrotropic hormone of the pituitary and found that exophthalmos occurred as readily and usually earlier in thyroidectomised than in intact animals.

Marine and Rosen conclude from these experiments that "the exophthalmos was brought about by the stimulating action of the thyrotropic factor of the anterior pituitary and that the thyroid gland took no positive part in causation." They consider that thyroidectomy stimulates the anterior pituitary to secrete more thyrotropic hormone. They found that removal of the superior cervical ganglion of the sympathetic abolished exophthalmos, whether caused by methyl cyanide or by the thyrotropic hormone of the pituitary, and conclude from this that the thyrotropic hormone causes exophthalmos by acting through a nervous mechanism.

Friedgood⁴ has observed the development of exophthalmos in 9 guinea-pigs out of 30 injected with anterior pituitary extract. In the first period following the beginning of daily injection of the extract, a prompt increase in the basal metabolic rate, associated with an increase in the basal pulse-rate and a decrease in the basal weight, was observed. The basal metabolic rate reached its maximum between the seventh and fourteenth day of treatment. After this the animal passed into a second period distinguished by a striking refractory state or remission, during which the basal metabolic rate returned to normal or might even fall below normal. Although slight prominence of the eyes occurred in several guinea-pigs towards the tenth day of the experimental period, when the basal metabolic rate was approaching its highest level, the exophthalmos was much more marked when it developed after the animal had entered the refractory period, and a striking exophthalmos was seen only in those animals which were injected over a period of several months, and especially in those which finally developed abnormally low basal metabolic rates. Friedgood concludes that these experiments indicate that the exophthalmos is produced independently of the thyroid secretion which causes the elevation of the basal metabolic rate, and that the anterior pituitary extract is more capable of inducing exophthalmos when the animal is not under the influence of hyperthyroidism but rather in a hypothyroid state. Scowen and Spence²³ also observed exophthalmos in 3 out of

14 guinea-pigs treated with the thyrotropic hormone of the pituitary.

RÔLE OF HYPOTHYROIDISM IN THE PRODUCTION OF EXOPHTHALMOS

The observation that hypothyroidism might, in certain circumstances, predispose to the occurrence of exophthalmos seems first to have been made by Kunde,⁸ who noted that although exophthalmos could not be produced in dogs by feeding with thyroid and only questionably in normal rabbits, marked exophthalmos developed when thyroid was fed to rabbits which had been rendered myxœdematous by thyroidectomy. Marine and his collaborators and Friedgood, in the experiments described in the previous section, observed that hypothyroidism exercised a similar predisposing influence on the production of exophthalmos by methyl cyanide and the thyrotropic hormone of the pituitary. The rare occurrence in man of progressive exophthalmos developing after subtotal thyroidectomy appears to be in some respects similar. Burch² has recently reported one case of this, Zimmerman²⁷ 8 cases, Naffziger¹⁹ one case, and Earnest and Serger³ one case. Naffziger and Jones²⁰ have discussed the surgical treatment of the condition. All these cases have been observed in the United States. I have seen two examples in this country. This condition will not be discussed in detail now as it is proposed to do this in a later communication. Its interest, for the present purpose, lies in the association between the development of exophthalmos and hypothyroidism. The usual sequence of events is as follows. A patient suffering from hyperthyroidism, with or without exophthalmos, undergoes subtotal thyroidectomy. Several months after the operation progressive exophthalmos develops, associated with ophthalmoplegia and, in some cases, with papilloedema and visual failure. This may occur when the patient is suffering from postoperative hypothyroidism as indicated by a subnormal basal metabolic rate, and it has sometimes followed the administration of thyroid extract in an attempt to correct postoperative hypothyroidism. Progressive exophthalmos occurring during postoperative hypothyroidism, recalls the experimental observation of Marine and his collaborators, and Friedgood, that exophthalmos could be produced by the thyrotropic hormone of the pituitary in animals that had been deprived of their thyroid glands or during a phase of relative hypothyroidism. Nevertheless, in some instances, the development of exophthalmos appears to have been precipitated or accelerated by the administration of thyroid extract in individuals during the phase of postoperative hypothyroidism.

Since thyroid extract is commonly administered either for the relief of myxœdema or in the treatment of obesity, it is naturally in these cases that we should expect to find examples of exophthalmos appearing after the administration of thyroid extract. Such cases cannot afford statistical evidence that hypothyroidism plays a part in the production of the exophthalmos. Nevertheless, in view of the experimental and clinical facts just cited, it is probable that it does so.

UNILATERAL EXOPHTHALMOS IN THYROTOXICOSIS

The exophthalmos, in the patient reported in this paper, was strictly unilateral. It is a minor puzzle that an ocular symptom associated with a state of general intoxication should sometimes be unilateral. In two other reported cases of exophthalmos following the administration of thyroid extract—H. U.

Møller's and Moorhead's cases—this symptom was unilateral. Unilateral exophthalmos sometimes occurs in spontaneous thyrotoxicosis. It was also rarely observed by Justin-Besançon and his collaborators in their experiments with sympathomimetic drugs, and Friedgood states that in all his guinea-pigs in which exophthalmos was produced by the thyrotropic hormone of the pituitary, the symptom was unilateral at some stage.

CONCLUSIONS

It is clear that the rôle of the thyroid in the pathogenesis of exophthalmos is by no means simple. Certain conclusions, however, can be drawn from the experimental and clinical facts already described. (1) The administration of thyroid extract or thyroxine to normal animals and human beings is not, as a rule, followed by the development of exophthalmos. (2) Exophthalmos can be produced experimentally by the administration to animals of drugs which stimulate the sympathetic nervous system. (3) Thyroxine appears to facilitate the action of such drugs in producing exophthalmos. (4) Exophthalmos can be produced by the thyrotropic hormone of the pituitary both in intact animals and in animals from which the thyroid has been removed, and there is some evidence that this hormone produces exophthalmos more readily in the presence of hypothyroidism. (5) Progressive exophthalmos may develop spontaneously following subtotal thyroidectomy in man even when the basal metabolic rate is subnormal, or may be precipitated in such individuals by the administration of thyroid extract. (6) Very rarely the administration of thyroid extract for the treatment of myxœdema, the relief of obesity, or some other purpose, is followed by the development of exophthalmos, and an example of this is reported. (7) It is probable, therefore, that when exophthalmos follows the administration of thyroid extract this is not a direct result of the action of the thyroid extract, but is due to some other substance which in certain rare individuals is produced in response to thyroid extract. Experimental evidence suggests that this substance may be the thyrotropic hormone of the pituitary.

EARLY AMPUTATION FOR SEVERE CRUSHING OF LIMBS

A NOTE ON TWENTY CASES

BY LOTFY ABDELSAMIE, M.B. Cairo

LATE RESIDENT SURGEON, KASR-EL-AINI HOSPITAL

(From the Surgical Unit, Kasr-el-Aini Hospital, Cairo)

THIS paper is written with the object of encouraging very early amputation in cases where limbs have been severely crushed. The temptation to delay intervention is easily understood; the gravity of the injury dissuades the surgeon from advising the remedy of prompt amputation, even though the pulse be satisfactory and the patient's condition fair. If on the contrary the general condition is less favourable, there is unfortunately a still more plausible pretext for waiting. I have twice been persuaded to adopt this policy of delay, and I have watched the state of two patients, neither of whom was exsanguinated, change in a couple of hours—in spite of saline infusion and warmth—from "fair" to "moderate," and from "moderate" to moribund. Their deaths and the knowledge that others were dying in like circumstance led me to consider the possibility of saving life by very early amputation.

The theme is of course by no means new. Thirty-three years ago Harvey Cushing (Ann. of Surg., 1902, xxxvi., 321) made a clear pronouncement regarding primary amputation that is still admirably modern, but this teaching is far too often forgotten. I venture to give it fresh emphasis by the following review of a rather intensive experience.

In fourteen months (1933-34) I have collected 20 cases with severely crushed limbs, all of which were treated at Kasr-el-Aini Hospital by early amputation. Of these, 19 were consecutive cases in the surgical unit, and were amputated by me; one was operated on by my colleague, Dr. Zacharia, and is included through the courtesy of Dr. Abdel Wahab Mooro, F.R.C.S. This last—a striking case of double amputation—will be specially referred to below.

Of the 20 patients 2 died; one of them suffered from other fractures and a severe head injury; the other, a woman aged 50, had her thigh amputated. In this woman and in all the surviving cases, the dominant lesion was crushing of the limb; other injuries of small importance, except in one patient who had fracture of the contralateral femur.

The method of treating these cases at present employed in the surgical unit at Kasr-el-Aini has been gradually developed under the guidance of its director, Prof. A. K. Henry, from the experience summarised in the following paragraphs. I shall therefore describe it last.

DEFINITIONS

It is essential in the first place to define what is meant by severe crushing of a limb. Imbert in 1911 pointed out that many crushes carry in themselves little or no risk to life (Jour. de Chir., 1911, p. 365). Amongst these minor crushes he included those which affect the hand and the anterior half of the foot¹ Leriche in 1926 once more emphasised the fact that these injuries must not be called severe crushes—*grands écrasements*; he reserves this term for more proximal injuries which present the following five

characteristics: (1) laceration and extensive stripping of the skin; (2) pulping of the muscles; (3) lesions of important vessels; (4) lesions of important nerves; (5) comminution of bone. Each of the 20 cases in my series conformed to this description and I have grouped them as follows:—

Group I.—Severe crushes involving the entire foot requiring amputation in the leg (3 cases).

Group II.—Severe crushes in the leg or forearm requiring amputation at a more proximal level in the leg or arm (7 cases—2 of arm; 5 of leg).

Group III.—Severe crushes in the leg or arm requiring amputation in the thigh or arm, or double amputation of the leg (10 cases—1 of arm; 1 (double) of legs; 8 of thighs).

Causation.—The crushing injuries in this series were due to the following causes: tram-cars, 8; motor-cars, 4; falls from a height, 4; machines, 2; fall of a stone, 1; train accident, 1.

Age.—The average age of the twenty patients was 17½ years; fourteen of them were aged 13 or under.

Sex.—There was only one female in the series; she was aged 50.

GENERAL CONDITION OF PATIENTS WITH CRUSHED LIMBS

Pulse-rate on admission.—A striking feature is the number of cases that were admitted with relatively slow pulses, in spite of their severe crushes, and in spite too of their youth. Thus in 10 patients the pulse was under 100 on admission. (See Table.)

Group.	Pulse-rate on admission.		
	Average.	Maximum.	Minimum.
I. (3 cases) ..	98	109	92
II. (7 ,,) ..	95	110	74
III. (10 ,,) ..	96	120	70

Two time-intervals were recorded in each case: (a) the interval between the time of accident and the time of operation, and (b) the interval between the time of admission and the time of operation.

The *accident-operation interval* (a) was 3½ hours or under in all except three cases—two in Group I. with intervals of 5 and 4½ hours respectively, both of which came to operation with fast pulses, and one anomalous case in Group III. with an interval of 7½ hours. The average *accident-operation interval* in the entire series of 20 cases was just over 2½ hours.

The *admission-operation interval* (b) averaged just over 1 hour, with a maximum of 2 hours and 10 minutes, and a minimum of 15 minutes.

The *pulse-rate during the admission-operation interval.*—Observation showed that the pulse-rate during interval (b) increased in 10 cases, in spite of restorative treatment, remained unaltered in 3 cases, and diminished in 6 cases. (In one early case the preoperative pulse was not noted.) In one case of the ten, where the pulse-rate increased, the pulse, which on admission was 100, became imperceptible before operation. The average *rise* in the other nine cases was 24 beats, with a maximal increase of 73, and a minimum of 2. The average *fall* in 6 cases where the pulse-rate diminished was 9.8 beats with a maximal fall of 16 and a minimum of 2.

Note.—In two cases, though the pulse-rate observed immediately before operation was faster than it was on admission, there had been an *intermediate fall* in rate under the influence of restorative treatment. The best moment for intervention was therefore missed in these cases, though fortunately without fatal result.

¹ This distinction is essential. Prof. Henry, at a meeting of the Egyptian branch of the British Medical Association in 1930, showed five cases with tarso-metatarsal crushes—treated conservatively by local resection of the crushed tissues—which had run aseptic courses.

EFFECT OF DELAY IN AMPUTATION

It is shown above that the average admission-operation interval (b) was short—just over one hour. In three cases, however, this interval was unavoidably extended, as the theatres were all occupied. The effect of this enforced postponement was striking. The pulses, which had been relatively slow and favourable at the times selected for operation, rose in each case to an alarming frequency during the comparatively short period of delay. The following paragraph gives details of one such case.

GROUP III. (No. 22359).—Dr. Zacharia's case of double amputation. Male, aged 12. Tram-car accident, Dec. 9th, 1933. Crush of the middle and upper part of right leg; continuity only maintained by skin. Left foot stripped of soft tissues, also left leg to level of lower third. Pulse on admission 100 (Temp. 36.8° C.). Accident-operation interval 1 hour 50 mins. Operation was fixed for half an hour after admission. Pulse at this time was still 100 and of fair tension. Operation had to be postponed for an hour. During this hour the pulse became imperceptible. Under ether, disarticulation at right knee; amputation at the middle of left leg. Duration of operation 30 minutes. Pulse again became countable at 140 about 20 hours after operation. Re-amputation, right thigh, on Feb. 21st, 1934. Discharged, healed, after 80 days.

Two other "delayed," but ultimately successful cases—one of the patients, besides a pulped right foot and lower third of leg, had fracture of the left femur—showed similar alarming accelerations. Thus in three patients when amputation could not be performed at the time fixed, the pulse-rate rose respectively in 2 hours from 96 to 140, in 1½ hours from 102 to 175, and in 1 hour from 100 to "imperceptible."

It will be seen therefore that these cases of postponed amputation serve, though unintentionally, as control experiments. They suggest two conclusions regarding the early treatment of severely crushed limbs. (1) When the pulse is favourable the opportunity of amputation should be seized at once. (2) Amputation will give patients with fast, or even imperceptible, pulses a chance—I think their only chance—of survival, provided always that these signs are due primarily to the crushing injury of the limbs themselves and not to manifest hæmorrhage or lesions in other parts.²

IMMEDIATE EFFECT OF EARLY AMPUTATION

The immediate effects of the operation seldom cause alarm. As a rule there was only a small increase in the pulse-rate, and a slight fall in blood pressure. In the most serious cases, too, where amputation was performed whilst the pulse was already poor and fast, the condition was no worse after it. Thus the average increase of pulse-rate taken immediately after operation in eighteen cases was 16 beats with a maximum of 60 and a minimum of *minus* 20—the pulse-rate falling 20 beats after operation. Other large rises of 60, 45, and 40 beats were recorded, the last in the fatal case with head injury, while the first two occurred in cases where the *time of operation was prolonged to 40 minutes*. In these two patients the pulse-rates had fallen during the admission-operation interval from 84 to 70, and from 88 to 75. A slow pulse therefore is no excuse for slow surgery in a case of crush. Operation, however, is sometimes prolonged (1) by the presence of multiple injuries, and (2) by mistaking a crush for a mere compound fracture; time is then wasted over local

² One anomalous case already referred to had a long accident-operation interval, 7½ hours. During the hour between admission and operation the pulse-rate remained at 110. The case is mentioned to show that exceptions occur. Rare exceptions, however, are unpredictable and give no excuse for delaying amputation.

treatment till the surgeon discovers that injured vessels and nerves call for amputation.

The average blood pressures taken immediately before and after operation in fourteen cases were respectively 115/70 and 100/60, an average fall of 15/10.

In view of these facts we can regard early, rapid, and simple amputation in cases of severe crush as relatively shock-free.

Treatment of Severe Crushes

To obtain this benign effect in amputation for crush it is necessary to insist on three things: (1) restorative treatment before and during operation; (2) proper anaesthesia; and (3) early and rapid intervention.

VALUE AND LIMITATIONS OF RESTORATIVE TREATMENT

Restorative treatment must never be omitted; on the other hand, if the patient fails to show a quick and favourable response, it must not be allowed to delay amputation. In those cases, too, which are unfavourable, either because of the proximal level of the crush, or because they come too late to hospital, the patient should be taken at once to the operation room, which, we have learnt, need *not* be an orthodox theatre. Such patients often require treatment nearly as urgent as that for hæmorrhage. The following example shows that there is no place for any refinement that will cause delay.

A man was brought into another service with both thighs crushed. The pulse-rate on admission was only 75. The case was marked "for immediate operation," but in the 30 minutes which elapsed while the theatre was prepared the pulse became uncountable, and amputation failed to save him.

After this event orders were given in the surgical unit that cases with severe crush must be taken to the first room available. There they are at once put under an electric cradle and given a large subfascial infusion of saline. Morphine gr. ¼ to ½, or codeine gr. ½ to 1 is administered according to age. Simultaneously—and this we think vital—local anaesthesia with novocain is begun so that the limb shall be ready for the first incision 20 minutes from the moment the patient enters the hospital. During this time instruments can if necessary be flamed.

ANÆSTHESIA

We have come, in the surgical unit, gradually to rely on novocain infiltration in performing these amputations. Novocain alone was employed first in this series in a Group II. case on Feb. 9th, 1934. We use from 80 to 150 c.cm. of novocain in ½ per cent. solution, with 7 drops of 1/1000 adrenaline per ounce, or 30 c.cm. The infiltration must be given time to effect full analgesia, for no pain whatever must be caused by the operation. It is instructive to keep a finger on the pulse throughout one of these amputations in a "poor risk" and to note how any painful, unblocked, stimulus will tend to make it imperceptible. With full analgesia, on the other hand, the pulse often remains unaltered, and indeed will sometimes improve.³

Technique.—A wide, encircling, weal is made in the skin; this requires from 20 to 40 c.cm. of novo-

³ Since this was written improvement in pulse and blood pressure has been noted immediately after operation under novocain by my successor in the surgical unit, Dr. M. H. el Zeneiny, in a most unpromising case of double leg-amputation which recovered. Dr. Botros Salib, resident surgeon at Kasr-el-Aini Hospital, through the courtesy of Dr. N. Makar, F.R.C.S., in November, 1935, reports a remarkable case (1935, No. 20999) in a patient, aged 15, where an uncountable pulse became 150, and an unregistrable blood pressure, 90/50, after a double thigh-amputation which he performed under gas-oxygen anaesthesia, according to the "urgent" technique described in this paper. The child recovered.

cain solution. The needle is then directed towards the principal nerves, and at least 10 c.cm. is injected into the neighbourhood of each. This quantity (80 c.cm.) is in general sufficient for full analgesia. An adult thigh, however, may require more novocain—up to 120 c.cm.

If the patient is nervous he may have gas-and-oxygen just before sawing the bone. This was given in this series first to a Group III. case on June 25th, 1934. It is surprising how often the operation can be completed under novocain only without distressing the patient.

Intra-neural injections are made individually into the nerves before they are divided, and it is important to inject each nerve once more at a higher level, when it is drawn down from the face of the stump, before it is finally severed in the attempt to avoid terminal neuroma.

Difficulties arise when other wounds require cleansing and excision. In such cases we prefer to administer gas-and-oxygen (or, as a second choice, ether) *in addition* to the novocain infiltration described above.

I have pointed out that the resistance of a patient with severe crush may be extremely frail though his pulse be slow and his blood pressure normal; it will soon break down if the operation lasts much beyond half an hour. For this reason when there are multiple injuries more than one operator should work at the same time.

THE AMPUTATION

The amputation in order to be rapid should be simple, and in some of the earlier cases guillotine amputations were performed. Little more time, however, is required for a circular amputation in the thigh, arm, or forearm, and for a flap amputation of the leg.

It is essential, because of the hurried and therefore incomplete preparation of the skin, to use a separate knife for dividing the deeper tissues. A couple of catgut sutures approximate muscles and fascia. The skin is closed with a few Michel clips to avoid bearing infection in from without by sutures. The wound is drained with half a split rubber tube. A good dressing for the stump is the sterile boric powder recommended by Sir Robert Jones.

Conclusions

1. Severe crushing injuries of the limbs can be clearly defined and are to be distinguished from minor crushes. Major crushes carry in themselves a grave risk of early death if amputation is not performed.

2. These serious injuries are compatible for a brief period with slow pulses and good blood pressures.

3. A slow pulse and good blood pressure indicate the moment of choice for intervention. This moment will soon pass.

4. The lives of patients with fast or even imperceptible pulses can be saved by immediate amputation when these signs are due to the presence of crushed tissues in the limbs and not to grave injuries elsewhere, or to external hæmorrhage.

5. Amputation therefore should be performed at the very earliest opportunity in every case of severe uncomplicated crushing of the limbs.

6. On admission to hospital the patient is brought at once to the first room available for performing amputation.

7. Restorative treatment and novocain analgesia are to be administered *simultaneously*, and the patient's limb or limbs should be analgesic and ready for

amputation within 20 minutes of his arrival in hospital.

8. Other injuries requiring general anæsthesia (gas-oxygen) for their treatment should, if possible, be dealt with during the amputation by another operator, and every effort must be made to limit the operative part of the treatment to less than half an hour.

9. Amputation under full novocain analgesia is a benign measure that does not shock the patient.

GALLOP RHYTHM AND THE PHYSIOLOGICAL THIRD HEART SOUND*

BY CRIGHTON BRAMWELL, M.D. Camb., F.R.C.P. Lond.

SENIOR ASSISTANT PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY

DEFINITION

UNDER certain conditions three instead of two sounds accompany each heart cycle. The familiar "lūb dūp," then becomes either "lūb dūpp dūpp" or "lūb lūb dūpp." From its resemblance to the sound made by a galloping horse, this triple rhythm has been called "gallop." When the additional sound follows closely on the second heart sound (Fig. 1B) the gallop is termed "protodiastolic," but when it immediately precedes the first heart sound (Fig. 1C) it is termed "presystolic."

My object in this communication is to point out the importance of distinguishing between the two types of triple rhythm. They are fundamentally different from one another.

The one is physiological; the other pathological. Protodiastolic gallop is quite compatible with perfect health. Presystolic gallop, on the other hand, is a sign of grave prognostic significance. It has been called "the cry of the heart for help." It warns us that the last reserves have been called up, and that the heart is struggling against desperate odds.

PRESYSTOLIC GALLOP—CLINICAL FEATURES

Let me give some actual figures in support of this statement.

In a consecutive series of 1353 cardiac cases seen in private practice during the three-year period 1930-32, I noted the presence of presystolic gallop in 63 patients. Of these, 1 has been lost sight of, 55 are now dead, and only 7 are still alive. That, I think you will agree, is sufficient evidence of the gravity of this sign in prognosis.

Only 15 of these 63 patients lived for more than

* Based on a paper read at the section of medicine at the annual meeting of the British Medical Association at Melbourne, 1935.

eighteen months after gallop was first noted. Table I. shows the duration of life in these patients.

struck by the fact that all the survivors were between the ages of 47 and 68. It is not unexpected that the 5 patients over that age should have died, but it is rather surprising that not 1 of the 16 patients under 47 years of age should have survived.

The explanation of the very high mortality amongst the younger patients is that gallop rhythm may develop in association with several different types of heart disease (Table III.). Acute endocarditis and chronic Bright's disease with high blood pressure accounted for 10 of the 16 deaths amongst the younger patients in my series; whereas, amongst the

older patients, essential hypertension and coronary arterio-sclerosis were the conditions most commonly found. These are more chronic diseases, and this appears to be the reason why the immediate prognosis in patients with gallop rhythm is rather less grave in the sixth and seventh decades than during the earlier period of life.

Twenty-six patients in this series exhibited signs of heart failure with venous engorgement; 25 of these had regular heart action. This is a very significant clinical observation, for congestive heart failure is notoriously much more common in association with auricular fibrillation than with normal rhythm. The finding of normal rhythm in association with congestive heart failure, in these cases, suggests that contraction of the auricle is essential to the production of gallop, and that presystolic gallop is incompatible with auricular fibrillation. This hypothesis is corroborated by the fact that, if a patient with gallop rhythm develops auricular fibrillation, the gallop always disappears, but will recur if normal rhythm is restored.

MECHANISM OF PRESYSTOLIC GALLOP

Further corroborative evidence concerning the rôle of the auricles in the production of gallop is derived from experimental observations. All workers

who have studied this problem by means of graphic records have found that the third sound in gallop is always synchronous with auricular systole.

Fig. 2, which is taken from one of many similar records made from my own cases, serves to illustrate this point. The upper tracing is an electrocardiogram and the lower a record of the heart sounds. The vibrations of the first heart sound (1) correspond in time to the R wave of the electrocardiogram, those of the second sound (2) to the T wave, and those of the gallop sound (G) to the succeeding P wave.

In order to explain the part played by auricular contraction in the production of gallop rhythm, I must briefly refer to certain events which take

FIG. 2.—Electrocardiogram (unstandardised) and phonocardiogram from a patient with gallop rhythm, to illustrate the time relations of the first (1), second (2), and gallop (G) sounds to the R, T, and P waves of the electrocardiogram.

place during the cardiac cycle. For this purpose it is convenient to divide that portion of diastole which follows the opening of the mitral and tricuspid valves into three stages—early, middle, or late diastole. When the mitral valve first opens † the pressure in the auricle is much higher than that in the ventricle, and during early diastole blood is rushing, with considerable velocity, through the mitral orifice. During mid-diastole, the rate of blood-flow from auricle to ventricle is greatly reduced, and the pressure in both chambers rises very slowly as blood flows in from the great veins. The third and final stage of diastole is occupied by contraction of the auricle. When this occurs, there is a sudden rise in the auricular pressure, and the rate of blood-flow through the mitral orifice is again increased. It is important, however, to remember that by the time the auricle contracts the ventricle is generally so full that it is capable of accepting very little more blood. I would ask you to note especially, that the most rapid filling of the ventricle occurs during early diastole.

That is what happens when the heart is beating slowly. Let us now see how this is modified when the heart beats more rapidly. The three records in Fig. 3 were made on myself during the period of recovery from an inhalation of amyl nitrite.

The upper tracing in each record is an electrocardiogram, the lower one a sphygmogram. In the first record, the heart was beating at a rate of 130 per minute. In the second record, taken 30 seconds later, the heart-rate had slowed down to 110; and in the third record, taken four minutes later, it had returned to normal, and was beating at 73. In the corresponding diagrams, I have represented by black rectangles auricular and ventricular systole, as measured from the electrocardiograms. You will see that, when the heart-rate is 73, auricular and ventricular

† The same applies to the right side of the heart.

systole are separated by a time interval of more than three-tenths of a second, whereas, when the heart-rate is 110, the interval is reduced to about one-tenth of a second; and, when the heart-rate is 130, there is no interval at all, auricular systole following immediately on ventricular systole.

In other words, in the first record, the entire diastolic portion of the ventricular cycle is occupied by auricular systole, and, even in the second record, auricular systole occurs very early in diastole. Now what is the significance of this? It means that when the heart is beating quickly, the rate of blood-flow from auricle to ventricle, which normally is most rapid during early diastole, is still further accelerated by contraction of the auricle. This I believe to be a factor of primary importance in the production of gallop rhythm. The abnormally rapid rate of ventricular filling causes sudden distension of the ventricle. This sets its walls into vibration, and so produces a pre-systolic sound. It does more than that. It produces a palpable pre-systolic impulse, to which I shall refer again.

But that, is obviously not the whole story. If it were, every patient with tachycardia would exhibit gallop rhythm. A second factor is essential—namely, a lack of tone in the ventricular muscle. Whereas the healthy ventricle is able rapidly to accommodate itself to sudden changes in the volume of its contents, the muscle of the ventricle which is lacking in tone is unable to do so. If suddenly stretched, it will oscillate to and fro.

This association of heart failure with tachycardia accounts for the grave clinical significance of gallop. The appearance of gallop means that the stroke volume of the failing ventricle is reduced to such an extent that the heart is no longer able to maintain an adequate output per minute, except by increasing its rate.

To sum up, I believe that the additional impulse

FIG. 3.—Electrocardiograms and optical carotid pulse tracings taken during recovery from an inhalation of amyl nitrite, to illustrate the curtailment of diastole during the tachycardia; (a) 80 seconds after commencement of inhalation, (b) 110 seconds after commencement of inhalation, (c) 360 seconds after commencement of inhalation.

in presystolic gallop is produced by sudden distension of the hypotonic ventricle and the additional sound by vibrations of the ventricular wall, both these phenomena being the result of the abnormally rapid rate of filling of the ventricle, when contraction of the auricle occurs early in diastole.

Other hypotheses.—It has been suggested that gallop rhythm may be due either to partial heart-block or to bundle branch block. My observations lend no support to this hypothesis. In my series,

partial heart-block was present in only 1 of the 33 cases in which an electrocardiogram was obtained. Bundle branch block, on the other hand, was relatively common. It was present in 7 of these 33 cases. This association, therefore, appeared to merit further inquiry. As a control, I examined all the electrocardiograms taken in the 1353 patients amongst whom my 63 cases of gallop occurred, and I found that there were 9 cases of bundle branch block without gallop rhythm. Thus neither did the majority of patients with gallop rhythm exhibit bundle branch

FIG. 4.—Electrocardiogram and phonocardiogram, from a patient with advanced mitral stenosis. (1) First heart sound (SM) systolic murmur, (2) second heart sound, (3) third heart sound, (DM) diastolic murmur.

block, nor did the majority of those with bundle branch block exhibit gallop rhythm. That bundle branch block and gallop rhythm should often occur together is not surprising, for both are signs of grave myocardial damage. There is, however, no evidence of a causal relationship between these two signs.

ACCENTUATION OF PHYSIOLOGICAL THIRD HEART SOUND

Let me now turn to the consideration of the "protodiastolic" type of gallop—the type in which the additional sound follows closely on the second heart sound (lūb, düpp, düpp). The term "protodiastolic gallop" is a bad one, because the epithet "protodiastolic" is used by physiologists to describe that phase of the cardiac cycle which immediately precedes the closure of the semilunar valves, whereas the additional sound in protodiastolic gallop occurs not before, but about one-tenth second after, the closure of these valves. There is a second objection to the term protodiastolic as applied to gallop. When the heart-rate is rapid, contraction of the auricle takes place early in diastole (see Fig. 3). Presystolic gallop then becomes "protodiastolic" in time. Actually the additional sound in protodiastolic gallop is nothing more nor less than an accentuated physiological third heart sound. Much confusion would be avoided if it were so called, and if the term "gallop" were reserved for the presystolic variety.

Now what is this "physiological third heart sound"? In many perfectly healthy young people, three instead of two heart sounds can be heard. The third heart sound is rather faint, and occurs about 1/10th sec. after the second heart sound. It can be brought out by any procedure which increases the rate of venous return to the heart, such for example as exercise or elevation of the limbs.

Thayer † of Baltimore studied this problem both clinically in man and experimentally in animals. In a series of 231 healthy young persons whom he examined, Thayer found that a third heart sound

† Thayer, W. S.: Trans. Assoc. Amer. Phys., 1908, xxiii., 326; 1919, xxiv., 71.

was present in 65 per cent. He also demonstrated the presence of a similar sound in dogs. This sound corresponded in time to the sudden distension of the ventricles which occurs early in diastole. He suggested that it was produced by vibration of the valve cusps, set up by the first rush of blood from auricle to ventricle.

This type of triple rhythm is always best heard in the vicinity of the cardiac apex. It can therefore easily be distinguished from that due to a "split" second sound produced by asynchronous closure of the aortic and pulmonary valves, which is audible only over the base of the heart. The third heart sound is a perfectly normal phenomenon. It has no pathological significance.

To sum up, I believe that the physiological third heart sound is produced by vibration of the A.V. valves, whereas the gallop sound is due to the vibration of the wall of the atonic ventricle. Further, the physiological third heart sound results from an acceleration of the blood-flow from auricle to ventricle, when the rate of venous return to the heart is increased, whereas the gallop sound is due to sudden distension of the ventricle, when the auricle contracts early in diastole.

Now how can we distinguish clinically between presystolic gallop rhythm and an accentuated third heart sound? In the first place, the gallop sound is generally accompanied by a palpable diastolic impulse, whereas the third heart sound is not. The normal cardiac impulse is a single thrust. The gallop impulse is a double wave. This gives to the hand the impression of a damped oscillation of the chest wall. Secondly the sounds in gallop (lūb, lūb, dūpp) are almost evenly spaced; whereas the accentuated third heart sound (lūb, dūpp, dūpp) is obviously more closely related to the preceding second than to the succeeding first heart sound. Lastly, the accentuated third heart sound is frequently present in patients with auricular fibrillation, whereas fibrillation and gallop never occur together.

Mitral stenosis.—Fig. 4 is taken from a patient with mitral stenosis. It shows the accentuated first heart sound and the duplicated second sound characteristic of that condition. It will be observed that the first component of the second sound is synchronous with the end of ventricular systole as indicated by the T wave in the electrocardiogram, and that the second component occurs about 1/10th second later. This second component is merely an accentuated third heart sound; it bears no relation to the P wave in the electrocardiogram, as was the case with the gallop sound. On the other hand, it does bear a constant relation to the preceding second heart sound, since it is synchronous with the opening of the mitral valve which follows the closure of the semilunar valves by about 1/10th second.

Although mitral stenosis is the condition par excellence in which to listen for an accentuated third heart sound (or, as it is commonly called, a "reduplicated second sound"), I have never met with presystolic gallop in a patient with this lesion. The explanation of this incompatibility is twofold. In the first place, gallop rhythm occurs only when heart failure is present or imminent. Now heart failure, in patients with mitral stenosis, is almost always the result of auricular fibrillation. This complication, as we have seen, excludes the possibility of gallop. Even in those very rare cases of mitral stenosis with heart failure and normal rhythm, the conditions present are such as to prevent the development of gallop. As I have pointed out, rapid filling of the ventricle is essential to the production of gallop,

but rapid filling of the ventricle cannot occur when the mitral orifice is stenosed.

CONCLUSION

In conclusion let me once again emphasise the grave significance of presystolic gallop, and the importance of distinguishing it from that type of triple rhythm which is due to accentuation of the physiological third heart sound.

SONNE DYSENTERY IN A MENTAL HOSPITAL

By J. J. LAWS, M.R.C.S. Eng., D.P.M.

ASSISTANT MEDICAL OFFICER, HORTON MENTAL HOSPITAL, EPSOM, SURREY

OUTBREAKS of dysentery due to infection with *Bacillus dysenteriae* Sonne have been described with increasing frequency in many parts of the world since Sonne in 1915 demonstrated that this organism is a cause of the disease. Many of these outbreaks have mainly affected children,^{1,2} but one of them,³ in a hospital staff, was confined to adults and clinically showed considerable similarity to the outbreak at Horton Mental Hospital. A prominent feature of the Horton epidemic was its high infectivity among the patients, although no member of the staff was taken ill. The first cases occurred in three adjacent wards on the male side, but almost at once further cases of the same type manifested themselves in widely separated parts of the hospital, and efforts to control the spread of infection were unavailing. Strict isolation of cases was practised from the beginning and possible causes of propagation—such as contaminated food or water-supply and inadequate treatment of foul linen—were investigated with negative results. The origin of the infection could not be discovered. It may have been previously present in a mild or symptomless form, as in some of the cases in the outbreak described by Felsen and Osofsky.⁴ The epidemic lasted some six weeks—from the latter end of March, 1935, until the middle of May—and was followed by a further slight outbreak at the end of June and the beginning of July. In all 113 cases were recorded during the main epidemic, and bacteriological investigations were made on 75 of these.

It is probable that in an outbreak of such proportions, occurring among the insane, a number of mild or possibly symptomless cases were missed, and this may explain the wide spread of the infection. Reference to carriers among patients in mental hospitals is made by Gardner⁵ who, in discussing so-called "asylum dysentery" quotes the opinion expressed by H. S. Gettings "that carriers are the main source of infection." A questionnaire on carriers circulated by a research subcommittee of the Royal Medico-Psychological Association⁶ showed that ten hospitals recorded carriers of both typhoid and dysentery—three of dysentery only—in all 28 cases. Although the infection appears to have been of the Flexner type, the same may well be true of Sonne dysentery.

Clinically the disease, though acute at the onset, was relatively benign and there were no deaths from the dysentery itself, although it appeared to hasten the death of a number of previously debilitated patients. The principal points in the clinical picture were a sudden onset, mostly with a sharp rise of temperature, varying from 99° F. to 104° F. (60 per cent. of the cases); vomiting (23 per cent.) often with considerable prostration; and abdominal pain and

discomfort (20 per cent.). About 90 per cent. of the patients had diarrhoea commencing at the onset; the motions were numerous and small, containing mucus, and in 23 per cent. of cases traces of blood. As a rule the temperature dropped in 24-48 hours, and the acute symptoms subsided in 1-7 days. The acute stage was often followed by obstinate constipation as noted by Fraser and Smith¹ at Aberdeen. In a few cases the illness was somewhat longer, but in these it was not necessarily more severe; indeed, many of those of short duration had a sharper reaction. Recovery was usually rapid and complete.

This description of the clinical findings is essentially similar to that given by other authors. In their "severe adult type" Felsen and Osofsky⁴ describe a sudden onset, high temperature, vomiting, prostration, and bloody diarrhoea. In their general description of clinical manifestations Fraser and Smith¹ note a temperature of 99°-103° F. (53 per cent. of cases) for 24-48 hours, vomiting (94 per cent.), diarrhoea (91 per cent.), blood in stools (13.5 per cent.), and abdominal pain (32.1 per cent.). Cann and Navasquez³ describe giddiness and malaise, abdominal discomfort and diarrhoea, and pyrexia (never over 101° F.) with return to normal in 48 hours—a slightly milder type of the disease.

BACTERIOLOGICAL INVESTIGATION

Specimens of faeces were obtained from each patient and inoculations were made on plates of McConkey's medium. Most of the plates grew *Bacillus coli* in abundance, but certain of them showed small pale colonies of a non-lactose-fermenting type. These were picked off, sub-cultured into broth, and also used for inoculating sugars. Specimens from 16 cases were thus examined, and of these 7 gave positive fermentation and agglutination reactions. In the fermentation tests lactose did not show the typical reaction (acid without gas) until the seventh day, and saccharose not until the tenth to twelfth day. Agglutination was also somewhat delayed, and it was found necessary to subculture in broth several times before a positive result could be obtained, with titres varying from 1 in 500 to 1 in 1250.

In view of the fact that fermentation was a lengthy procedure and that one was apparently dealing with an outbreak of Sonne dysentery, further investigations were limited to plating on McConkey's medium, and agglutinations of broth cultures, as advocated by Gardner.⁵

In all some 75 cases (66 per cent. of total) were investigated by cultural methods, of these 22 (30 per cent.) showed the Sonne organism. The positive results might have been higher if it had been possible to make more than one culture in each case. About seven weeks after the commencement of the outbreak the decline in the number of fresh cases made it possible to undertake a second investigation, and a single specimen was again examined from 70 of the original cases. Only 3 of these gave a positive result—four weeks, three weeks, and one week after the onsets.

It is generally agreed that as a rule the organisms disappear rapidly from the stools. Cann and Navasquez³ say "a few days"; Fraser and Smith¹ state that of 53 cases 41 were negative in a week. Of the remainder, 4 were negative by the second week, another 4 by the third week, and 3 more by the fourth. Only 1 was positive for seven months.

In the early stages of the investigation serum agglutination tests were made on a few cases. Ten sera were thus tested within a fortnight of the onset, and nine of these gave a positive reaction with titres varying from 1 in 25 to 1 in 600. A more complete investigation was made later, at the same time as the second examination of faeces—seven weeks after the commencement of the outbreak. Of the original 113 cases 83 were examined, and of these 51 (60 per

cent.) were positive, 41 of them at a titre of 1 in 125 (the highest dilution used). In all agglutination tests standard suspensions and sera only were used.

THE SECOND OUTBREAK

As previously mentioned the second outbreak was small, being confined to a single ward. Cases had occurred there previously, but had always been transferred to isolation, and there had been no fresh cases, either in this ward or elsewhere, for about six weeks. Ten patients were affected during a period of three weeks. They all showed the usual clinical symptoms and were at once removed to isolation. Sonne's bacillus was isolated in only two cases, but clinically there was no doubt of the diagnosis in all the ten patients. The stools of the 48 patients remaining in the ward were also investigated—a single culture only being made in each case, with the interesting result that three hitherto unsuspected cases were found to be harbouring Sonne's bacillus.

Although these patients never showed clinical symptoms, precautionary measures were taken and the stools of each of them were examined again on eight separate occasions during the following six weeks. Two were found to be still positive at the end of a month; thereafter all three were negative. In view of this evidence of infection in patients showing no clinical symptoms, it was decided to carry out serum agglutinations on as many as possible of the 48 cases in the ward, all of whom might presumably have been exposed to the risk of infection. A total of 34 sera were tested and 25 of these (including the three culturally positive cases) proved positive in dilutions varying from 1 in 25 to 1 in 1250. As, however, a small dose (125 million organisms) of a prophylactic vaccine had previously been given to 13 of these 25 cases (again including the three with positive cultures) the value of these results is somewhat doubtful. It is of more significance that of the 21 cases not vaccinated a positive result was obtained in 12—nearly 60 per cent.

CONCLUSIONS

Sonne dysentery is a disease of high infectivity, usually acute in onset and of moderately benign course. Most cases soon become free from infection, but a small number continue to harbour the bacilli, while others pass organisms in the stools without having shown any clinical symptoms. Both these forms of carrier may play a large part in spreading the disease.

Agglutination of standard suspensions of Sonne's bacillus by patients' sera can be obtained in a large proportion of cases showing clinical symptoms, even if culture has proved negative, and also in some cases in which there is no clinical evidence of the disease. In the former type agglutination is valuable in confirming a diagnosis, while in the latter it is possibly useful in detecting carriers or latent cases.

I wish to thank Dr. W. D. Nicol, medical superintendent of Horton Mental Hospital, for his kind encouragement and for permission to publish these cases, and also Dr. S. A. Mann, of the L.C.C. Central Pathological Laboratory, Maudsley Hospital, for his help and advice.

SARCOMA OF THE DUODENUM

BY GERALD SLOT, M.D., M.R.C.P. Lond., D.P.H.

SENIOR PHYSICIAN, ROYAL WATERLOO HOSPITAL, LONDON, AND ROYAL HOSPITAL, RICHMOND; PHYSICIAN IN CHARGE, RHEUMATISM SUPERVISORY CENTRE, LONDON COUNTY COUNCIL; AND

M. H. FRIDJOHN, M.B. Dub., B.Sc.

CLINICAL ASSISTANT, ROYAL HOSPITAL, RICHMOND

SARCOMA of the duodenum is rare, and comparatively few cases have been reported. As Rolleston¹ has pointed out, sarcomata involve the duodenal tract more extensively than carcinomata; and in sarcoma dilatation due to softening by the growth occurs, whereas in carcinoma obstruction is commoner. Very few cases of primary sarcoma have been described and therefore it is difficult to form conclusions. We have discovered the following recent records:—

Strauss et al.² describe a lymphosarcoma of the duodenum located distally to the ampulla of Vater. The patient survived two years after a gastro-enterostomy and a course of deep X ray therapy.

In the radiographic diagnosis of duodenal tumours Brdiczka³ points out that of 84 cases of intestinal myoma, only 6 were found in the duodenum. He quotes a case of myosarcoma of the duodenum in a female of 60, who died suddenly from lung embolism a week after operation. The tumour was situated in the right epigastrium, was attached to the bulb of the duodenum, and was the size of a foetal head. There were no metastases, and the gall-bladder was not involved.

Pfundt⁴ reported a case of spindle-cell sarcoma of the duodenum occurring in a female aged 41. She had had pain in the right epigastrium for a few weeks, and the pain was almost continuous. She had lost 20 lb. in weight—there was no vomiting or nausea. Her general nutrition was good and there was no distension of the abdomen. A tumour the size of an orange was found in the right epigastrium and appeared to be attached to the liver. A blood count showed 10,800 leucocytes. At operation the tumour was found to be a large thick-walled tumour, filled with cysts, attached to both the gall-bladder and the pars superior duodeni. Processes of the tumour, 2–3 cm. long, were found infiltrating the lumen of the duodenum. The duodenal mucous membrane was normal, and after closing of the abdomen the patient made an uneventful recovery.

LaRoque and Lee Shiflett⁵ reported the case of a female, aged 48, who complained of a mass in the upper thigh. Various small nodules had been removed during the previous thirteen years. There was a history of previous gastric trouble consisting of gastric fullness, vomiting and pain, but no hæmatemesis. The patient was found to be emaciated and anæmic. The liver was large, and there was a palpable mass in the right upper quadrant. Radiography showed that the duodenal bulb was much dilated, and an abdominal operation revealed a hard tumour the size of a hen's egg inside the lumen of the duodenum. The pyloric portion of the stomach and the first three inches of the duodenum were removed. After temporary rallying the patient died suddenly from dilatation of the stomach. The tumour proved to be a spindle-cell sarcoma.

Libman⁶ has collected 54 cases of lymphosarcoma of the bowel—15 of which were in the duodenum. None of the patients were below ten years of age, and 9 between ten and twenty years. He states that sarcoma is very rare, and has not recorded any recoveries. Possibly its course may be delayed by X ray and radium therapy.

Andersen and Door⁷ recorded a case of a male, aged 37, who had had tarry stools for the previous seven weeks. This was associated with loss of weight, œdema of the lungs and feet, and a lump in the right side of the abdomen. No abdominal pains or fever. There was a tender swelling in the right upper abdomen which projected two inches below the margin of the liver; it was hard and irregular. This patient was not operated upon, and died six days after admission from shock following extensive hæmorrhage into the gastro-intestinal tract. At the autopsy

the tumour was found to involve the posterior aspect of the second portion of the duodenum and the posterior and inferior aspects of the third portion of the duodenum. The anterior surface of the duodenum was free. Histologically it was found to be a primary leiomyosarcoma; it had caused compression of the inferior vena cava and thrombosis of the iliac veins. The authors of this paper state that the only other case of leiomyosarcoma was reported by Salis in 1920.⁸ This case was that of a man, aged 40, who was found post mortem to have a large tumour attached to the duodenum above the duodeno-jejunal juncture. He had previously had an operation for gastric symptoms from which he recovered, leaving a tumour and fistula, and it was four months after the second operation for the removal of this tumour and fistula that he died.

Berstein records⁹ a case of myoma of the duodenal bulb, while Gehrig¹⁰ gives an account of polyposis of the duodenal bulb.

Our patient was a male, aged 38, and was first seen by one of us (M. H. F.) on Feb. 27th, 1934. He said that while dressing he had been seized with severe abdominal pain and had collapsed. There was no vomiting, but within a couple of hours he passed some large tarry stools. He had no previous history of ill-health and had never before suffered from any abdominal discomfort.

On examination he showed extreme shock; he was very pale and his pulse was hardly perceptible. Nothing definite was found on examination of his abdomen; there was no tenderness and no rigidity. On palpation per rectum nothing could be found, but proctoscopic examination revealed melæna. The heart sounds were normal and the blood pressure 100/70. He was first of all treated for shock with atropine and camphor, and heat was applied externally. Heart stimulants were given by mouth, and during the next three days his condition improved somewhat and the melæna diminished.

On March 2nd he was sent to the West London Hospital with a diagnosis of "bleeding duodenal ulcer." On admission he was given a blood transfusion—(14 oz., group 4). The next day he had much melæna. He was treated by rectal salines, followed by Lenhart's diet. During convalescence the patient complained of blurred vision in the right eye. Mr. H. P. Gibb reported: "both

FIG. 1.—The duodenum opened to show the tumour in its posterior wall, adherent to the pancreas.

discs have blurred margins—there is a large oval hæmorrhage over the right macula, and a smaller hæmorrhage on the nasal side of the right disc. In both fundi there are spots of choroidal disturbances, which may be the result of hæmorrhages which have cleared up." A barium meal showed a hypertonic stomach. The duodenal cap would not fill, and there appeared to be a small crater where the duodenal cap is usually situated. The evidence was suggestive of duodenal ulcer.

Blood counts.—In March a blood count showed: red cells, 1,400,000; hæmoglobin, 23 per cent.; colour-index, 0.82; white cells, 8000; marked polychromasia, with poikilocytosis and anisocytosis; nucleated red cells rare. The patient was given ferri et ammon. cit., grs. 40 t.d.s., and a blood count on May 4th showed: red cells,

4,000,000; hæmoglobin, 76 per cent.; colour-index, 0.95; white cells, 8000.

Course of illness.—Discharged in July, 1934, he was seen again later that month when his teeth were removed as a possible focus of infection. Between July and October he had no trouble whatever; he gained about $\frac{1}{2}$ st. in weight, and stated that he had never felt better in his life. But on Oct. 23rd, and until the end of the year, he complained of vague abdominal pain, which he described as "indigestion." This pain was relieved by alkalis. From the findings at the previous X ray examination the

FIG. 2.—Microscopical sections of tumour: low power and high power.

possibility of a small duodenal ulcer was still kept in mind, and early in November he was given Larostidin injections, 5c.cm. daily, for three weeks. Between January and March, 1935, his symptoms gradually abated. On March 8th he was seen again in a state of collapse, and his condition exactly resembled his first attack. He was again removed to the West London Hospital. On this occasion his hæmoglobin was 24 per cent., but it rose to 42 per cent. with a month's intensive iron treatment. A barium meal showed irregularity and irritability of the duodenal cap. The patient remained in hospital until May, when he was discharged owing to his developing a mild attack of scarlet fever. On discharge he was advised to return later for laparotomy. From May until August he was free of symptoms, but on August 14th he collapsed while walking in the street and was brought home. His condition was again similar to his previous one, and he was admitted to the Royal Hospital, Richmond. Here he was found to be extremely collapsed and suffering from shock and internal hæmorrhage. Nothing could be found on palpation of the abdomen. A blood transfusion was advised, and while preparations were being made the patient died.

Post-mortem examination revealed the body of a fairly well-nourished man. The heart and lungs were normal. The liver contained no secondary deposits. As will be seen from Fig. 1, there was a tumour the size of a small hen's egg at the junction of the first and second parts of the duodenum, adherent to the pancreas. The tumour was in the posterior wall of the duodenum and had ulcerated through the lumen. The mucosa was congested and red, and the bowel full of blood. No metastases or glands could be found. Microscopically, Dr. David Murray reported the tumour to be a spindle-celled sarcoma (Fig. 2).

This case is interesting in view of the temporary recoveries and the excellent condition of the patient between the attacks. Clinically the outstanding feature was hæmorrhage, and there was no vomiting or evidence of obstruction. No positive evidence of a duodenal lesion was obtained and the patient was well nourished at the time of decease.

We are indebted to Dr. Geoffrey Konstam for the notes of the case while at the West London Hospital.

SPONTANEOUS FRACTURE IN ACUTE AND SUBACUTE OSTEOMYELITIS

REPORT OF TWO CASES

BY R. C. TATHAM, F.R.C.S. Eng.

LATE SURGICAL REGISTRAR, MIDDLESEX HOSPITAL, LONDON

FRACTURE is a recognised though uncommon complication of chronic osteomyelitis, usually due to excessive removal of bone for cure of a chronic abscess or in sequestrectomy. But fracture in acute or subacute cases is exceedingly rare. Thus Capener and Pierce¹ in a series of 1086 cases of osteomyelitis found it in 18 (1.7 per cent.) and of these only 2 cases were classified as subacute and 1 as acute. The following cases therefore seem worthy of record.

CASE 1.—A boy, aged 14, was admitted to the Middlesex Hospital under the care of Mr. Pearce Gould on Oct. 30th, 1931, with a history of having eight weeks previously developed a painful swelling of the lower end of the left thigh and knee, thought at first to be tuberculous. After a few days a popliteal abscess had been opened and drained, and the pus from it showed staphylococci. There was no definite history of injury. On admission there was a wound on the inner side of the left thigh just above the knee discharging much pus; the knee was slightly flexed and there was varus deformity with great pain on attempted movement. The general condition was good and the temperature and pulse normal. Radiography (Fig. 1) showed a fracture through the metaphyseal region with impaction and angulation, and a general patchy rarefaction of the whole of the lower end of the shaft. Some periosteal new bone was visible proximal to the line of fracture. The deformity was corrected under general anaesthesia and the limb put in plaster with a window. The patient was returned to his local hospital on Nov. 26th, 1931. A letter from his doctor dated Oct. 3rd, 1935, stated that he was at work in a garage; no operation had been performed since leaving Middlesex Hospital, but a sinus was still present though repeated X ray examinations failed to show any sequestrum.

CASE 2.—A boy, aged 9, was admitted to Dudley-road Hospital, Birmingham, on June 6th, 1935, under the care of Mr. Parsons, with an acute painful swelling of the lower end of the left thigh of four days' duration. There was a history of mild injury while at school the day before the onset, but it was not sufficiently severe to prevent him running about at play afterwards. On admission (five days later) the pulse-rate was 106 and temperature 102.2° F. A popliteal abscess was opened and drained and the limb put up on a back splint with foot-piece and side splints. The lower half of the thigh remained extremely tender for the first week, but the local and general condition gradually improved, the temperature becoming normal on the eighteenth day after admission. X ray examination (Fig. 2) on the eleventh day showed a fracture with slight displacement through the metaphysis of the lower end of the femur, general patchy rarefaction of this region, and some periosteal new bone, most conspicuous on the inner

and popliteal surfaces. The wound continued to discharge, and on Sept. 27th a further radiogram (Fig. 3) showed a sequestrum, which on removal proved to be a portion of the cortex, the lower end being just above the line of fracture which was no longer visible. There was a massive involucrum.

In neither of these cases was there a history suggesting that fracture preceded the infection. In the first case fracture was noted eight weeks

then absorption is, of necessity, osteoclytic and slow, the bone being a dead structure. Further reference to the above cases will show that they were both of the less acute type, the first being at first regarded as tuberculous, and that the fracture occurred through a widespread area of rarefaction in the metaphyseal region. There is also a noticeable lack of new bone-formation in the region of the fractures (Figs. 1 and 2). Furthermore the after-histories show that sequestrum-

FIG. 1 (Case 1).—Radiogram of lower end of femur showing fracture through a diffusely rarefied area in the region of the metaphysis. Periosteal reaction slight and not related to fracture.

FIG. 2 (Case 2).—Radiogram of lower end of femur showing fracture with very little displacement through metaphyseal region. Slight but definite rarefaction. Some periosteal new bone posteriorly.

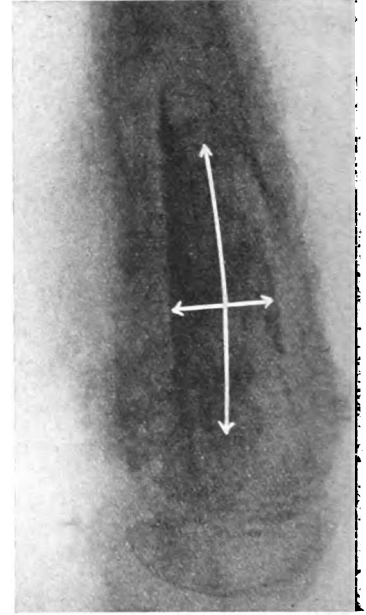

FIG. 3 (Case 2).—Radiogram of lower end of femur showing sequestrum (indicated by white lines) lying in a massive involucrum. Line of fracture not visible.

after the onset of the disease and in the second case on the fifteenth day of the illness—i.e., earlier than in any other recorded case. In both cases back splints had been applied after the initial drainage, which did not involve the removal of any bone. The exciting trauma must therefore have occurred while the limb was on the splint or after the splint had been removed for a dressing. There was no note of any knock or sudden bend, so that it must have been very trivial. In Capener and Pierce's earliest case fracture occurred at the junction of the middle and lower thirds of the femur eight weeks after drainage, and was due to a blow on the uncovered but supported thigh; the medulla had been drained. In the cases here recorded no bone had been removed for drainage.

When osteomyelitis follows its usual course there is simultaneous weakening of bone from vascular and osteoclytic absorption, and strengthening of it from periosteal new bone-formation; so that by the time the original bone has been absorbed sufficiently to allow of fracture enough new bone has been formed to prevent such an accident. If the rate of absorption outstrips that of new bone-formation, and if the absorption proceeds throughout the thickness of the shaft, then fracture becomes possible. The conditions necessary for rapid absorption are a high proportion of vascular tissue to bone and patent vessels. Such conditions are found in the metaphysis and in the more subacute type of case. Should all the vessels become thrombosed by the acuteness of the process,

formation was minimal and in Case 2 not immediately related to the fracture. Thus the clinical and X ray findings and after-histories support the explanation of causation which has been given.

My thanks are due to Mr. Pearce Gould, surgeon to Middlesex Hospital, and to Dr. F. W. Ellis, medical superintendent, and Mr. K. O. Parsons, surgeon to Dudley-road Hospital, for permission to publish the cases.

TWO CASES OF TWIN-LOCKING

By J. STANLEY COLEMAN, M.B. Lond.

LATE DEPUTY MEDICAL SUPERINTENDENT, FOREST GATE HOSPITAL, LONDON, E.

APART from certain features of interest, the rarity of this obstetric complication would be sufficient reason for placing these cases on record. According to von Braun¹ the condition occurred only once in 90,000 deliveries in Vienna.

CASE 1.—Mrs. A., aged 29, a 2-gravida, was admitted to the Forest Gate Hospital at 6.30 A.M. on Nov. 21st, 1934. Labour had commenced about an hour earlier with a sharp vaginal hemorrhage, on account of which she was sent into hospital. The last menstrual period began on March 1st, so that the pregnancy had advanced to about the thirty-eighth week.

Vaginal examination revealed an os that admitted two fingers, the cervical canal had not been taken up, and no placenta could be palpated around the margin of the os. A presenting vertex lightly engaged at the brim could

¹ Eden and Holland's Manual of Midwifery, London, 1925, p. 358.

be palpated with the fingers through the unruptured membranes. The pelvis was judged to be roomy, and on inquiry the patient told me her first infant weighed 12 lb. at birth, and the labour was quite normal. Abdominal examination was difficult owing to frequent strong contractions; over-distension of the uterus was noted but hydramnios was not present. Only one fetal heart could be heard all over the lower abdomen and only one breech palpated with certainty at the fundus. Between pains, however, I thought I could palpate a second head slightly to the left of the midline at the lower pole of the uterus. A tentative diagnosis of twins was made, both fetuses presenting by the vertex. A catheter specimen of urine showed a cloud of albumin.

Labour was allowed to proceed and twelve hours later vaginal examination revealed the os three-quarters dilated, the cervix thick all round with some oedema of the anterior lip. A fetal head was half engaged at the brim, extended, and lying in the left occipito-posterior position. Morphia and later chloral were administered and the patient obtained a little respite from the pains that continued strong and frequent. Fifteen hours later examination revealed no further advance and the woman was becoming exhausted. The abdomen was now very tender and any movement or palpation distressed the patient considerably.

At 9.30 A.M. on Nov. 22nd, 28½ hours after the onset of labour, chloroform was administered and a careful pelvic examination made. I found two heads firmly impacted at the brim. The foremost head was lying face to pubes in the extended position and a loop of cord was felt around the neck. The second head was firmly wedged under the chin, against the neck and upper part of the thorax of the first fetus. The back of the second fetus was in the midline anteriorly.

The cervix was first gently dilated to its maximum, the second head pushed up out of the brim, and the first head completely rotated and flexed as much as possible. I always use my left hand for the manoeuvre of manual rotation, so that I was able to apply the forceps without removing my hand from the uterus. The first head was gently drawn down to the vulva and delivered after removing the forceps, and it was soon found to be quite impossible to deliver the trunk, owing to the extreme tension on the cord and the loop drawn tightly around the neck which could not be slipped over the head. The cord was divided between forceps and the first fetus, a live female weighing 5 lb. 12½ oz., rapidly delivered. Sharp intrapartum hæmorrhage now occurred so I applied the forceps to the second head and delivered another live female weighing 5 lb. 13½ oz. ten minutes later. There was some post-partum hæmorrhage which was checked by rapidly expressing both placentæ from the uterus.

The case was one of binovular twins with two separate placentæ (one of the battledore variety) and no membranous fusion. The puerperium was uneventful and the patient left hospital with the vigorous twins twelve days later.

I would draw attention to the following points: (1) The difficulty of establishing firmly the diagnosis of twins without X ray examination. In my experience the diagnosis is often missed. (2) The frequency with which loops of cord around the fetal neck cause primary extension of the head leading to complications such as persistent occipito-posterior positions, "face" and "brow" labours and prolapse of an arm. In this case extension of the leading head allowed the second head to become impacted under the chin. (3) Intrapartum hæmorrhage after delivery of the first twin should be an indication for immediate delivery of the second fetus.

CASE 2.—Mrs. B., aged 27, a primipara, was admitted to the hospital on Nov. 16th, 1934, as a case of albuminuria of pregnancy. There was oedema of the legs and vulva and some puffiness of the face. The blood pressure was raised to 160/100 mm. of mercury, and the urine loaded with albumin. Some degree of hydramnios was noted and apart from the discomfort of the distended abdomen there were no symptoms. A diagnosis of twins had already been made and verified by X ray examination. The last

menstrual period began on March 3rd, so that on admission the pregnancy had advanced to about 37 weeks and the expected day of confinement calculated in the first half of December. The pelvis was judged to be roomy; external pelvimetry revealed normal measurements, and on vaginal examination nothing abnormal was noted.

With rest in bed, special diet, and mild eliminative treatment on classical lines, the general condition improved, the oedema completely disappeared, and the albuminuria diminished. The membranes ruptured suddenly on Dec. 5th at 10.30 P.M. and the patient went into labour. She was examined at 11.30 P.M., the os admitted two fingers, the cervix was not taken up, and a head was lightly engaged at the brim. The second vertex could easily be palpated per abdomen in the midline anteriorly. By 6 A.M. the first head was well engaged, the dilatation very slow (three fingers), and it was noted the vertex was extended and lying almost face to pubes. At 1.30 P.M. on Dec. 6th, 15 hours later, the os was fully dilated, the extended head was found impacted low in mid-cavity, lying face to pubes with marked moulding, the parietals overlapping the displaced frontal bones, and a large caput over the anterior portion of the left frontal bone. The pains were strong and frequent and with the thought that the fetus was probably not very big the patient was left for spontaneous delivery to occur.

By 4 P.M. it was manifest that the obstruction was more serious. The anus and vulva were oedematous, the patient much distressed, and the lower abdomen tender on palpation. There had been no advance at all and interference was obviously indicated. A general anæsthetic was administered and a careful pelvic exploration revealed the extension of the leading head to be due to a hand being doubled under the chin. The second fetal head was found entering the pelvic brim along with the lower part of the neck and upper part of the thorax of the first fetus. The back of the second fetus was in the midline anteriorly.

The second fetal head was pushed up and to one side, the leading head completely rotated and flexed as much as possible after dislodging the hand from under the chin. The whole manoeuvre was carried out with the left hand, so that the forceps could be applied without removing my hand from the uterus. The leading vertex was drawn down to the vulva and owing to the distorted (somewhat quadrilateral) shape of the head, bursting of the oedematous perineum seemed inevitable. Right lateral episiotomy was at once performed and the head quickly delivered. The birth of the first infant, a living male, weight 5 lb. 8½ oz., was followed by a sharp intrapartum hæmorrhage. The second bag of membranes was ruptured digitally and the forceps applied to the second head, which was gently drawn down to the vulva, and the delivery of the second living male infant, weight 6 lb. 14½ oz., effected. There was a fair amount of post-partum hæmorrhage, which ceased when the massive placentæ were expelled from the uterus eight minutes later. The episiotomy incision was accurately sutured with silkworm gut.

The placentæ exhibited partial fusion along their margin of contact for a distance of 4 in. by strong bands of connective tissue and placental substance. No large vessel passed over the fetal aspect of the line of fusion, all the main vessels terminating in each placenta some distance from the fused margins. There were two complete chorionic and amniotic sacs, but along the area of contact the two chorionic membranes had become loosely applied to each other, but could be separated easily by gentle traction. One of the placentæ was of the battledore variety. I regard the case therefore as one of binovular twins.

(1) In this second case the primary extension of the head appeared to be due to a hand and arm being impacted under the chin. This I have found to be a frequent complication in difficult deliveries due to extension and malrotation of the fetal head. (2) In both these cases the anæsthesia and manipulations were carried out with the patient in the left lateral position. By using the left hand to carry out the manoeuvre of rotation of the head the application

of the forceps is greatly facilitated and intra-uterine manipulation reduced to a minimum. (3) When the condition of twin-locking is suspected it is infinitely preferable to interfere early rather than to wait for the impaction to become very severe, when a destructive operation on the leading head would become necessary.

THE INHALATION OF COMMON PINS

BY J. MCFARLAND, M.D. Liverp., F.R.C.S. Edin.,
D.L.O.

ASSISTANT THROAT SURGEON TO THE ROYAL LIVERPOOL CHILDREN'S
HOSPITAL AND ALDER HEY HOSPITAL, LIVERPOOL

THE following case may interest bronchoscopists, especially as it raises debatable questions.

On Oct. 7th, 1934, a boy aged 13 inhaled a common pin, and a radiogram showed it lying head-downwards in a posterior bronchiole of the right lower lobe. The same day a bronchoscopy failed to discover the pin, nor could I see in the bronchial epithelium any evidence of the transit of a foreign body. No physical signs developed in the chest, and the only symptom was pain in the right hypochondrium, probably reflex in origin and due to irritation of the diaphragm. Several attempts were made to remove the pin under the fluoroscope, but without success, and after seven months there was no change except that the pin had moved downwards and outwards. The boy was quite well and but for a cough showed no physical signs. Apparently neither the pin nor the manoeuvres had affected him.

On May 8th, 1935, he coughed the pin into his mouth and brought it to hospital. It proved to be an ordinary common brass pin, tin-coated and about 1½ in. long. A small amount of mucopus adhered to it and there was a

little erosion of the tin coating. He has been quite well since.

In two other comparable cases the pin has remained in the lung for six and twelve months respectively, without causing any apparent pathological changes.

One is led to inquire about the state of the lung epithelium in contact with the foreign body during these seven months, and whether a pin could be coughed up without there being any infection present. It has been stated that sooner or later infection will supervene and that therefore every effort must be made to retrieve the foreign body. My own feeling, based on these three cases, is that where a foreign body of small cross-section passes to the utmost depths of the lung, it does not at first set up any dangerous processes. Unless the foreign body can be seen through the bronchoscope it is well to wait until low-grade infection has dilated the minute

Lateral and antero-posterior radiograms showing position of the pin.

passages, rather than risk injuring the tissues by seeking for it under the direction of an external observer.

I am indebted to my senior, Mr. P. Leathart, for permission to publish this case.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF NEUROLOGY

At a meeting of this section held on Jan. 16th the chair was taken by Prof. F. L. GOLLA, the president, and a paper on

The Spleen, the Liver, and the Brain

was read by Prof. B. BROUWER (Amsterdam). The relationship between these three organs, he said, could be viewed in a wider aspect since the introduction of the study of the so-called lipidoses. Since Kinnier Wilson had first described hepatocerebral degeneration, knowledge of the clinical syndrome had been extended, and it had been shown that the pathological changes might be widespread in the central nervous system. Various writers had reported families suffering from hepatocerebral degenerations in which some members had no lesions in the brain, and had suggested that the primary lesion should be sought in a damaged liver which produced or passed toxins having a special effect on the central nervous system. There were, however, still differences of opinion. Prof. Brouwer had, he said, had the

opportunity of studying three brothers suffering from this disease, with a classical clinical picture: extrapyramidal motor disturbances, brownish-yellow granular pigmentation of the cornea, the so-called ring of Kaiser-Fleischer, and mental symptoms. In two of them autopsy had shown hepatic cirrhosis, splenic enlargement, and symmetrical lesions of the corpus striatum. The neuroglia cells of Alzheimer had been seen. These lesions seemed typical of Wilson's disease, but there had also been a bilateral pathological change in the forebrain cortex: small cavities, increase of glia, and newly formed blood-vessels. The changes were chiefly in the frontal area, gradually diminishing towards the occiput, and strongly suggested a congenital inferiority.

The idea that the toxin in hepatocerebral degeneration was formed in the liver had been influenced by analogy with Kernikterus (icterus gravis neonatorum). In this condition there was usually erythroblastemia in the blood and liver and spleen. This was, however, secondary and not always present. It represented regeneration after destruction, the destruction having caused the icterus. The brain changes varied from case to case, but the globus pallidus and corpus subthalamicum were chiefly affected. Maternal

toxæmia had been proved to be the cause of this condition. In typical cases of Kernikterus the yellow coloration was not due to liver disease but to hæmolysis. The analogy with hepatocerebral degeneration was not, therefore, a sound one.

A case of hæmochromatosis had been studied by Prof. Brouwer's Institute. This rare condition was characterised by melanoderma, liver cirrhosis, and diabetes, and was almost confined to males. This patient, however, had also had disease of the brain: character changes, followed by confusion, restlessness, incontinence, and somnolence. After an attack the use of the hands and legs and speech had been impaired. He had also shown dysarthria, dysphagia, emotionalism, tremor in both arms, stiffness in the facial muscles, and hypotonia in limb muscles. There had been no pyramidal signs. At autopsy there had been the usual signs of hæmochromatosis, a typical Laennec cirrhosis, fibrosis of the spleen and pancreas, and the cerebral lesions of Wilson's disease. Two kinds of pigment were found in this condition: hæmosiderin and a brown melanin pigment derived from protein. At one time the diabetes and later the cirrhosis had been regarded as the primary factor; but Prof. Brouwer thought there was a disturbance of iron and protein metabolism, of unknown endogenous origin. The pathological changes were all coördinated with one another. Hæmochromatosis associated with pseudosclerosis was not Wilson's disease, but the two conditions could not be very different. Hepatocerebral degenerations probably belonged to that class of metabolic disturbances which were characterised by lesions in organs with congenitally poor resistance. The ætiological factor was unknown.

The question arose whether such disturbances could be limited to special organs. Relevant arguments were found in the "lipoidoses," the three principal ones being Schüller-Christian's disease, Gaucher's splenohepatomegaly, and Niemann-Pick's splenohepatomegaly. The first showed defects in the bones, especially of the skull and pelvis, and the cell deposit was cholesterol. In Gaucher's disease it was kersin and in Niemann-Pick's disease it was partly lecithin and partly phosphatide. Niemann-Pick's disease was associated with amaurotic idiocy and was characterised by the accumulation of an enormous quantity of large, pale cells filled with fine drops of lipid, the so-called foam cells, in liver, spleen, and other organs. There was a general disturbance of lipid metabolism. M. Bielschowsky had regarded amaurotic idiocy as a result of this disturbance. Prof. Brouwer described a case of typical amaurotic idiocy and the post-mortem findings, which supported Bielschowsky's view. The patient was a girl, aged 18 months, with classical symptoms: idiocy, commencing hypertonia of the extremities, and increase of the deep reflexes. In the macula the typical white area with central red spot was found on both sides. The child had had several epileptiform convulsions, developed contractures in the limbs, and died at the age of 2½. Autopsy revealed the typical findings; the nerve-cells of the cortex, basal ganglia, midbrain, pons, medulla, and spinal cord were all swollen and distended by lipid deposits. Myelinisation was retarded in all four lobes, in the cord, and in the thalamus, but almost normal in the hypothalamus, corpus striatum, and midbrain. Changes were very marked in the cerebellum; in many places the granule cell layer was considerably atrophied and there was increase of glia everywhere. It was obvious that normal

fibres might proceed from cells filled with lipid. The pathological changes were limited to the ectoderm, thus supporting Schaffer's theory that the fundamental process in amaurotic idiocy was a primary affection of the nerve-cells, but in the spleen of this case typical foam cells had been found, though without splenomegaly. During the last months of life the quantity of lecithin in the blood had increased in proportion to the cholesterol.

In conclusion, he said that all the diseases he had mentioned, except Kernikterus, were disturbances of metabolism, and such disturbances need not be general but might show a localisation in certain organs. It depended on the inborn factor which organ would suffer. Chemistry must take the lead in further researches on these subjects.

DISCUSSION

Dr. J. G. GREENFIELD asked where the poisons arose, and welcomed Prof. Brouwer's attention to the neglected corpus subthalamicum.—Prof. BROUWER replied that he thought the poison might be intestinal, but admitted as a research worker that he had seen several cases where the liver had been practically normal, and he did not really know.

Prof. A. MAYER thought that Prof. Brouwer's Kernikterus material might throw some light on the lesion of the globus pallidus appearing at or soon after birth described by Hallevorden and Spatz, and its identity with the status demyelinatus of C. and O. Vogt. He asked if there had been any evidence of birth trauma.—Prof. BROUWER replied that he was sure there was no birth trauma.

Dr. E. PARKES WEBER cited some cases of family cirrhosis where all the usual ætiological factors were absent; he thought such cases were a form of congenital developmental disease: inborn disease which either appeared at birth or was potential at birth and appeared later. Three diseases of this kind were associated with cirrhosis of the liver: Wilson's disease, hæmochromatosis, and generalised congenital developmental telangiectasia (Osler's disease). The most likely explanation of the cirrhosis in Wilson's disease was that it was a congenital developmental dysbiotrophy. Hæmochromatosis belonged to the same group as hæmatoporphyrinuria and alcaptonuria. Why Osler's disease showed cirrhosis was a puzzle, but it certainly did.—Prof. BROUWER observed that there were many cases of lipodystrophy without mental symptoms. He had no experience of Osler's disease.

Dr. GORDON HOLMES, proposing a vote of thanks, commented on the curious systematised susceptibility of parts of the nervous system and mentioned manganese and other poisonings. The primary agents must, he thought, be multiple.

TUBERCULOSIS ASSOCIATION

At a meeting of this association held at Manson House on Jan. 17th a discussion was opened by Dr. NOEL D. BARDSWELL on

After-care of the Tuberculous in London

The organisation of after-care in London differed, he said, from that elsewhere by reason of the enormous size of London and the unavoidable division of responsibility. Each of the London boroughs made its own arrangements, and in consequence considerable variation existed as to the character and scope of this provision. Although in the main London

was faithful to the voluntary principle, the care committees were tending more and more to become official bodies, with, e.g., a hitherto voluntary secretary replaced by a secretary employed and paid for by the borough. The Metropolitan Boroughs Standing Joint Committee had recently expressed the view that care committees should consist of eight borough councillors and seven other members representing voluntary charitable agencies operating in the borough. He doubted whether a care committee of this composition would prove as useful as one chiefly composed of individuals prepared to render personal service to particular patients. On the question whether a single officer or a committee was the better, he thought that when both were first-class there was probably little to choose, but he leaned to a committee with a good secretary, a committee having the advantage that it tapped more sources, spread responsibility, and had greater opportunity of raising funds in various ways. Care work, in the broadest sense of the term, was the determining factor in the future of most patients, but to be effective it must be continuous. There was often a hiatus of a year or more during a patient's stay in an institution. Much might happen in a home during this time. The services of a visiting almoner might prove a valuable link between the patient, his home, and those interested in his after-care. On the vexed question of funds for care committees the L.C.C., Dr. Bardswell said, had always taken the view that a financially aided care committee would merely be an additional relief agency, but although in principle he thought this was a sound view, assistance to be effective must sometimes be immediate, and a care committee should have command of a small fund—preferably raised by themselves—for this emergency work.

PULMONARY CASES

Not the least important extension of after-care facilities had been the establishment of the industrial settlements at Papworth and Preston Hall, but such settlements though valuable were of course no solution of the after-care problem, since only some 4 per cent. of the patients admitted proved suitable colonists. Work centres run on commercial lines had obvious limitations, but were useful within these limits; while the handicraft classes now to be found in 15 boroughs were one of the most pleasing features of after-care work in London. Woolwich and Deptford had gone further, and had instituted cookery classes for women patients and the mothers and wives of patients. Another growing and effective factor in after-care was the L.C.C.'s policy of rehousing overcrowded households which contained a case of active tuberculosis. During last year 33.5 per cent. of the households recommended for removal by the public health department at County Hall secured new accommodation. The principle of letting houses on a new estate to a tuberculous family was not universally approved. Recently he had addressed a conference on this subject at Oxford and was surprised at the amount of opposition aroused by the proposal, experienced public health workers in the county expressing horror at the suggestion that their nice new municipal cottages should be contaminated by the tuberculous.

Dr. Bardswell concluded with a brief review of the L.C.C.'s scheme for the boarding-out of children from an infected home, or to allow of a mother going away for treatment. On the average 150 children were away at any one time, 25 per cent. to remove them from risk of infection and 75 per cent. to allow

of a patient going to an institution. Other directions in which public authorities had in late years eased the burdens of care committees were by the provision of extra nourishment, of dentures, of beds and bedding, and clothes. Finally, he suggested that A.P. refills, even if no longer clinically effective, were an aid in after-care, inasmuch as they kept a patient in constant touch with skilled knowledge of tuberculosis—a most valuable thing.

SURGICAL TUBERCULOSIS

Dr. J. G. JOHNSTONE (Princess Mary's Hospital for Children, Margate), who followed, confined himself mainly to after-care in children who had suffered from tuberculous disease of bones and joints. It was generally agreed that at the present day a well-organised follow-up system in connexion with surgical tuberculosis was essential for several reasons: (1) Tuberculosis was a generalised infection which manifested itself in active processes at one or more sites, and, having been quiescent, might light up again at any time in the old lesion or elsewhere. (2) Recrudescence in the early stages generally arose insidiously, unknown to the patient, requiring a practised clinician to recognise its occurrence. (3) Arrest of the disease in the case of tuberculous bones and joints did not mean the final end-result. With the arrest of the disease, few cases retained full range of function in the affected part. Partial immobilisation and "posturisation" had to be maintained over a long period to prevent a recurrence of activity and to maintain the optimum position of the area relative to the rest of the body. Between 66 and 75 per cent. of cases of tuberculous arthritis resulted in osseo-fibrous ankylosis which, in the case of children, took several years to become organised and consolidated after quiescence. (4) To maintain the optimum position with relative immobilisation and relief from pressure or friction, some firm mechanical apparatus had to be worn, and this necessitated supervision, repair, and often renewal—depending on the site of disease, age of patient, and other factors—the appliances being eventually gradually discarded at the appropriate time. (5) Tuberculous disease of spine and hip might result in permanent disability from deformity or shortening, necessitating the constant provision of a spinal support or surgical boots. Such conditions left untreated resulted in chronic spinal arthritis in middle life from mere anatomical malalignment. (6) It was frequently necessary to contemplate surgical interference at some future date, and the choice of the proper time should be left entirely in the hands of the surgeon who had had charge of the patient during the active stages of the disease.

It was of vital importance, he said, that effective surgical after-care should be carried out by the surgeon undertaking the in-patient treatment, to ensure continuity in the programme of treatment extended over a period of years. Moreover, his experience at several hospitals working along different lines had taught him that effective supervision in the after-care resulted in cases being admitted at an earlier stage in reactivation, with minor deformities. It was noticeable that cases which came from areas with effective after-care organisation were in better condition than those from areas where arrangements were of an indifferent character. A very comprehensive system of after-care had been developed by the L.C.C. in connexion with cases of surgical tuberculosis—no small achievement in a city like London. Consideration of the after-care began

almost as soon as the patient reached hospital, when an environmental report was received. Notice was taken of the home conditions, and allowance was made in the ambulant period at the hospital before the case was recommended for discharge. The speaker described in detail the procedure followed in three groups of cases: (a) those discharged to their own homes within the administrative area of the L.C.C.; (b) those discharged to convalescent homes or other institutions; (c) those discharged to other areas outside the administrative area of the L.C.C. Ninety-five per cent. of the cases of tuberculous disease of bones and joints discharged to London from Princess Mary's Hospital, Margate, were supervised in their after-care from the central hospital. This after-care clinic was held at the County Hall every Monday. In spite of the steady increase in the attendance roll, there had been no increase in the incidence of reactivation, and there had been a reduction in the development of gross deformities requiring correction. The position was remarkable when compared with the state of affairs only a decade ago, when the percentage of readmissions was high and the disease and deformity well established. Though the after-care clinic entailed considerable time, trouble, and labour, it had proved well worth while. Any orthopaedic hospital failing to have a well organised and conducted follow-up scheme was, in his opinion, accomplishing only half its function to the community which it served.

Vocational training, Dr. Johnstone added, was a sound economic and preventive proposition, and he would like to see it extended to a greater number of cases. This country had not yet reached the American standard in the rehabilitation of the cripple into industry, but there were great possibilities.

LIVERPOOL MEDICAL INSTITUTION

At a meeting of this institution, held on Jan. 9th, with Dr. C. O. STALLYBRASS, the president, in the chair, a paper entitled

Some Aspects of Bronchial Carcinoma

was read by Dr. E. T. BAKER-BATES. After pointing out that this disease is recognised more often than it was 25 years ago, he gave reasons for doubting whether there has been a comparable increase in its incidence. The first symptoms, he said, might be hæmoptysis, paroxysmal dyspnoea, or those of pleural effusion or localised pulmonary infection, and in the early case there might be no physical signs. In diagnosis the position of the heart and trachea were of greatest significance. With collapse of the lung, which followed stenosis of a main bronchus, they were displaced towards the affected side—a most suggestive finding. Later, dullness on percussion, diminished breath sounds, and reduction in the hemidiaphragmatic movements were the commonest signs. Radiography might show nothing if the growth was confined to the lumen of the bronchus or if it was retrocardiac. Again the shadows cast by collapse of the lung and the suppuration following bronchial obstruction might obscure the picture. Lipiodol was useful in the early diagnosis and in pleural effusion after air-replacement. It indicated the upper margin of the growth and showed the extent of the intra-bronchial growth (rat-tailed bronchus). The outline of the growth was nearly always convex; fusiform narrowing was probably due to chronic inflammatory changes. Dr. Baker-Bates had never seen any dele-

terious effects due to the lipiodol. The value of bronchoscopy in the early diagnosis and treatment could not, he thought, be over-estimated. The technique had now been mastered sufficiently to permit of its being performed with ease and without discomfort to the patient under local anaesthesia, and it added a certainty to the diagnosis which could not be obtained in any other way, by giving information as to the site and extent of the lesion, and enabling tissue to be removed for section. If any successful treatment could be evolved, its success depended on early diagnosis; one should therefore be prepared to investigate with the bronchoscope all patients presenting any of the recognised manifestations of the disease. Patients with advanced bronchial carcinoma suffered from the mechanical effects of a blocked bronchus, and the introduction of radon seeds which would keep the lumen patent made their lives far more bearable by allowing bronchoscopic drainage and preventing suppurative complications. The duration of the disease depended upon whether the patient had a patent bronchus or not. If the bronchus was occluded the course was rapid, death occurring from inflammatory changes in the "drowned lung" which formed a suitable nidus for pneumonic consolidation and abscess formation. When the growth remained extrapulmonary the progress was slow, and the patient might live in comparative comfort for a couple of years. Deep X ray therapy often gave relief, especially where there were large mediastinal glands producing mediastinal obstruction, but it did not seem to influence the primary growth in the bronchus.

Dr. A. ADAMS said that since the foundation of the tuberculosis service, patients suffering from pulmonary diseases had been coming more and more to the tuberculosis officer for diagnosis, and the voluntary hospital now rarely saw them. This was well illustrated in the figures published by the department in Manchester, where in 1932 there were 138 deaths from cancer of the respiratory system and a record of 89 cases of pulmonary carcinoma given, almost all of bronchial origin. The Manchester area appeared to be the most fertile source of this disease in the kingdom, thus approximating to the mining districts of Czechoslovakia and Saxony. Severe hæmorrhage was a rare complication, but staining of the sputum occurred in about 40 per cent. of cases at some period. The symptoms and physical signs found in the chest were usually caused by occlusion of a bronchus or by pressure. Metastases in the central nervous system were commoner than the published reports suggested. The type of disease described by continental physicians as lymphangitis carcinomatosa had been missed by many clinicians, the X ray appearance being misread as miliary tuberculosis. The recent work of Dudgeon and Wrigley, showing how groups of malignant cells in the sputum could be rapidly recognised, was a valuable addition to the clinical examination. Lipiodol for demonstrating the presence of a growth should be used with great care as it might prevent a patient later being submitted to deep therapy treatment, and was usually not necessary for diagnosis.

Prof. HENRY COHEN emphasised that nearly a quarter of all cases had an acute pneumonic or pleuritic onset. Rarely the radiological features of miliary tuberculosis were so closely simulated by carcinoma that only by post-mortem examination could a diagnosis be established. Nearly 10 per cent. of all cases had a positive Wassermann reaction, though pathological examination proved the lesion to be

malignant; and the association of tuberculosis with malignancy was by no means infrequent. "Unresolved pneumonia" was a seductive though dangerous term, and whilst the radiologist might be justified in using it, the physician should recognise the possibility of an underlying carcinoma in all such cases. A special technique might reveal the presence of malignant cells in the sputum, though a negative finding was of no value. Three of the cases of proved bronchial carcinoma under Prof. Cohen's care had had as their presenting symptom intense lumbar pain, although there was no radiological evidence of metastasis; later the pain radiated up the spine to the neck. The possibility of metastases giving no radiological signs of their presence was offered as an explanation, though no opportunity for confirmation by the post-mortem examination had been afforded in these cases. The superior pulmonary sulcus tumour, described by Pancoast, was usually a bronchogenic carcinoma at the pulmonary apex. He had seen many cases of generalised metastases from a primary carcinoma of the bronchus so small that there was neither clinical nor radiological evidence of its presence during life. All the patients he had referred to surgeons had died within twelve months of operation—with one exception, that of a man with a pedunculated carcinoma removed from the right main bronchus, who was alive and well two years later. Both X ray treatment and radium had given very disappointing results.

Mr. H. V. FORSTER recalled Yankauer's suggestion that in all cases of hæmoptysis in which no tubercle bacilli could be found bronchoscopy should be carried out, and that the endoscopist should encourage the physician to look upon this useful direct method as one not carrying a great risk. As Dr. Baker-Bates had pointed out, the endoscopist could help to relieve pulmonary collapse due to bronchial narrowing, and he himself had been able once to remove to a considerable extent with punch forceps a growth involving the left main bronchus with restoration of ventilation. The question whether deep X ray therapy could be helpful seemed to have been answered favourably by many observers in America. Some patients had experienced relief for as long as five years.

Dr. P. H. WHITAKER emphasised the importance of screen examination in cases of early bronchial carcinoma. It was often possible to detect deficient air-entry before it became clinically apparent by noting limitation of diaphragmatic movement on the affected side. The obstacles to efficient irradiation were difficulty of access and the fact that a large enough dose could not be at present directed on to the tumour. This accounted for the poor results.

Dr. HOWELL HUGHES said that from a surgical point of view there were four main types of bronchial carcinoma; being classified according to radiographical and bronchoscopic findings. (1) Intrabronchial carcinoma, in which the early radiographical appearance was a slight increase in the shadow of one hilum, and later, with bronchial obstruction, a dense wedge-shaped shadow spreading from hilum to periphery. (2) Mediastinal, which spread from a large bronchus into the mediastinum, but not peripherally, giving increase of the mediastinal shadow. (3) Peripheral, which spread outwards, and might invade the chest wall, while mediastinal glands were not involved. Radiographically an almost rounded shadow was seen in the lung, making contact with the hilum. Pancoast's tumour described by Dr. Baker-Bates was probably of this type, and merely because of its position and size caused the complications described,

and so did not justify a separate group. (4) Parenchymal, which radiographically showed a rounded shadow in the lung distinct from the hilum, with late glandular involvement. In types 3 and 4 lobectomy or pneumonectomy might bring about cure, but in type 1 the most that could be done was to relieve obstruction by means of radon seeds.

Mr. COSBIE ROSS read a paper on Lipiodol in Surgery of the Biliary Passages.

NEW INVENTIONS

APPARATUS FOR CONTINUOUS ADMINISTRATION OF SALINE SOLUTION

THE accompanying drawing shows an apparatus I have designed for giving continuous drip intravenous saline, for use with Crookes's bottles of gum or glucose saline.

It consists of two corks to fit the bottles, each provided with a long and a short tube. When the bottle is inverted, saline runs out of the short tube, while the long tube allows air to flow in, thus preventing a vacuum forming. The short tubes are connected to a Y-piece, below which is an adjustable clamp and a glass visible-drip connexion. From here the saline runs down through a metal U-tube in a thermos flask, where it is heated to the required temperature before it reaches the vein. The whole apparatus is on a stand which places it at the right height above the bed.

The tubes and corks can be removed en bloc from the stand, boiled in a steriliser, and fitted to the bottles. Boiling water is put in the thermos, and the apparatus is ready for use. The two bottles are emptied alternately, the empty one being clamped off and changed for a full one; thus the administration of saline may be kept up for as long as is required.

The apparatus has proved very satisfactory in use, its advantages being that it is easy to sterilise (the contents of the bottles being already sterile), that it never runs out, and that the saline is administered hot. If necessary it can be used to administer saline rapidly instead of by the drip method, simply by unscrewing the adjustable clamp above the visible drip connexion.

It has been made for me by Jack Storey, Station-road, Ashford, Middlesex.

C. E. WATSON, M.R.C.S.,
House Surgeon, King Edward VIII
Hospital, Windsor.

ROYAL SANITARY INSTITUTE.—Mr. John Wilson, chief architect to the department of health for Scotland, will open a discussion on the sanitation and planning of flats at a meeting to be held at the institute (90, Buckingham Palace-road, London, S.W.) on Tuesday, Feb. 11th, at 5.30 p.m.

REVIEWS AND NOTICES OF BOOKS

A Text-book of Fractures and Dislocations

Third edition. By KELLOGG SPEED, S.B., M.D., F.A.C.S., Professor of Clinical Surgery, Rush Medical College of the University of Chicago. London: Henry Kimpton. 1935. Pp. 1000. 50s.

THIS book presents an exhaustive account of the subject of fractures and dislocations; for example, three and a half pages are devoted to fractures of the laryngeal cartilages. The pathology and mechanism of each fracture is dealt with at some length, and as the unusual types of fracture receive considerable attention, the importance of the work to the practising surgeon is obvious. Different methods of treatment of each fracture are considered and compared—e.g., every type of suture material and every incision used in repair of fracture of the patella is described. The author mentions in the preface that he has been at pains to avoid fads; but from the point of view of the surgeon faced with the immediate treatment of a case, a definite description of the method employed by the author, and evolved by his own experience, would have been helpful. The references in the text and at the end of each chapter to the work and writings of various surgeons should be of great use to the research student.

An individual feature of the book is the method of illustration by line drawings which are tracings from original radiograms. These are well drawn and are most convincing. It is interesting to find that in applying suspension traction for fractures of the femur, the author uses the body-weight of the patient as the extending force, and does not apply weights to the limb. This method, an excellent one in practice, seems to be too little used. Its great advantage is that it allows considerable mobility of the patient, and of the limb as a whole, without upsetting the line of traction or the finely adjusted suspension of the splint. All weights suspending the splint hang at the head of the bed, well out of the way. The section on operative treatment contains an excellent account of the methods of application of skeletal traction, with instructions for avoiding its two main dangers—infection and over-extension. There seems to be some ambiguity in the description of the angle of flexion advised in the treatment of supracondylar fracture of the humerus. An angle "never more than 60," and flexion "as far as possible" are mentioned in the same paragraph (p. 374). Full supination is recommended for this fracture, a position which Böhler and others have condemned on very definite grounds.

We can congratulate author and publishers on a work which is well-produced, clear and precise, and pleasant to read.

Die Differentialdiagnose chirurgischer Erkrankungen

By W. BRAEUCKER, Hamburg; H. F. O. HABERLAND, Köln; H. KLOSE, Danzig; and M. ZUR VERTH, Hamburg. Edited by H. F. O. Haberland. Berlin: Walter de Gruyter and Co. 1935. Pp. 1180. R.M.52.

THIS large book on surgical diagnosis is intended, the authors affirm, for students and practitioners. It may well prove to be too large a work to appeal to undergraduates, but on the other hand many surgeons will wish to possess it as a work of reference. It is well and simply written and easy to read, and deals systematically with the diagnosis of surgical

diseases of all parts of the body. The illustrations, over 450 in number and of high quality, include not only photographs of surgical affections but radiograms of diagnostic interest and very useful diagrams of methods of examination. The section dealing with the nervous system is particularly valuable in this connexion. An attractive and rather unusual feature of the book is the short epitome of treatment which follows the account of each disease.

The work is a creditable compilation of present-day surgical diagnosis.

Practical Zoology

By H. R. HEWER, A.R.C.S., D.I.C., M.Sc. Lond., F.L.S., Lecturer in Zoology, Imperial College of Science and Technology. London: Hutchinson's Scientific and Technical Publications. 1935. Pp. 118. 5s.

THIS book contains a set of detailed instructions for observation and dissection of the usual type-specimens used in an elementary course of zoology, together with an account of methods of fixation, preservation, section cutting, and mounting of specimens. There is nothing particularly original in the subject matter nor in the manner in which it is presented. Those, however, who are about to teach elementary zoology in universities or schools will do well to refresh their memories by a study of its pages and may find that it fits their ideas closely enough to enable them to base their course on it. To students working on their own this book should prove extremely useful.

1. Elementary Morphology and Physiology for Medical Students

Second edition. By J. H. WOODGER, D.Sc., Reader in Biology in the University of London. London: Humphrey Milford, Oxford University Press. 1935. Pp. 498. 12s. 6d.

2. Practical Biology for Medical Students

By C. J. WALLIS, M.A., Master-in-charge of Biology, University College School, Hampstead. London: William Heinemann (Medical Books) Ltd. 1936. Pp. 247. 12s. 6d.

1. The large number of books on elementary zoology which have appeared during the past twenty years may roughly be divided into two classes: those which describe the structure of a series of animals in entire isolation from one another (the majority), and those which deal with general principles but do not give sufficient facts to make those principles intelligible to the beginner. As an introduction to comparative morphology Dr. Woodger's book is one of the best we have seen. The structure of the types and the embryology of the vertebrates are well described with good illustrations, and the facts are coördinated and are given a real significance in relation to general principles such as adaptation and evolution. It is in fact a book which can be read with interest during a course of dissection. The emphasis is laid on morphology. This for beginners is probably advisable, and the author has not given as much life to his chapters on physiology as he has done to those dealing with structure. It is to be regretted that in the last theoretical chapter, which has been rewritten in the second edition, the evidences for the theory of evolution are not discussed in the light of the relevant facts which are all supplied in various places but not coördinated.

2. This is an improvement on other elementary practical books in that an attempt is made to illustrate the principles of biochemistry and physiology from animals as well as from plants. The experiments suggested are such as can be performed without complicated apparatus. It is to be regretted that simple experiments in animal physiology such as the action of cilia, muscles and nerves, fertilisation, growth, and regeneration are not included. The directions for dissection, preparation of slides, and observation of embryological material are good, but not better than those to be found in many other text-books.

Traité de physiologie, normale et pathologique

Tome X. (deux fascicules). Edited by G. H. ROGER, Hon. Professor of Physiology, and L. BINET, Professor of Physiology in the Faculty of Medicine, Paris. Paris: Masson et Cie. 1935. Pp. 1580 (2 vols.). Fr. 220.

ALTHOUGH this work consists of 11 volumes, that now issued, Vol. X., completes it, for the eleventh volume has already run into two editions. Vol. X. is the longest of all, and is divided into two separately bound parts, the second of which deals mainly with the special senses. Multiple authorship makes inappropriate any general criticisms; some of the articles would make books in themselves. It would almost be easier to review the Bible, which is at least divided into the Old and New Testaments. The subjects now treated are as follows: psychophysiology, cerebellum, pons and medulla, spinal cord, cerebrospinal fluid, cranial nerves, autonomic nervous system, physiology of skin, touch, speech, hearing, vision, taste, smell. The style and approach of the numerous authors are as various as their subjects, but the articles on the cerebellum and the autonomic system may be picked out as most in keeping with the modern physiological viewpoint. The former is based on phylogenetic as well as on experimental studies, and is as sound an account of cerebellar function as could be written in the present state of the subject. The latter provides an excellent historical résumé of the numerous generalisations which have been attempted from time to time on the function of the vegetative nervous system, besides giving a good account of its physiology. The bibliography of the article on the cerebellum is good, and the list of references to literature on the sympathetic and parasympathetic appears to us to be exhaustive.

The other articles, with the exception of that on speech which treats the subject historically and is extremely interesting, are dominated by the old "anatomical" tradition; they are encyclopædic but lack vitality. One must hasten to add that reflex action is dealt with in Vol. IX. of the series, and in a comprehensive work of this sort a place must be found for the bread and butter as well as for the cakes and ale. Although some of the sections make dull reading, this is often inevitable and does not detract from their value for purposes of reference. The well-illustrated and full account of the cranial nerves and their lesions is excellent, and is perhaps the most conscientiously written part of the book. The article on the cerebro-spinal fluid also contains much useful information, clinical and pathological as well as physiological. The remainder of the articles are no more, and sometimes rather less, than one would expect. The physiology of the skin is treated thoroughly and unimaginatively, but is misplaced, having nothing to do with the nervous system;

there is a separate section on the physiology of touch. If the skin article had been omitted and that on vision correspondingly enlarged (and treated as methodically), the balance of the book would have been improved.

Speaking generally, we can definitely recommend this volume as useful, particularly to those wishing to restore contact with the often neglected French literature. In places it is outstanding, and those who contemplate adding it to their library will be well advised to consult its pages on the subjects in which they are especially interested and be guided by their impressions after such a survey. Most of them will proceed to business.

Diseases of the Nose and Throat

For Practitioners and Students. By CHARLES J. IMPERATORI, M.D., F.A.C.S., Professor of Clinical Otolaryngology, New York Post-Graduate Medical School; and HERMAN J. BURMAN, M.D., Instructor of Clinical Otolaryngology to the Medical School. London and Philadelphia: J. B. Lippincott Company. 1935. Pp. 723. 35s.

THIS book is, as stated in the preface, written to supply answers to the questions with which the practitioner and senior student are constantly confronted, "what is the diagnosis of this condition and how shall I treat it?" The arrangement is unusual, in that symptoms, diagnosis, and treatment are placed first, and the pathology and causation of the diseases are considered at the end of each discussion; this has the advantage of enabling the busy reader to find the treatment recommended quickly, but it often makes it difficult to visualise the precise condition under discussion. For instance, the symptoms, diagnosis, and treatment of ulceration of the nasal septum are described, and at the end of the section we find, under the heading aetiology, that it may be caused by such general diseases as tuberculosis and syphilis which, however, have not been mentioned in the paragraph on treatment.

The book is arranged throughout in tabular form, which does not make for easy reading; indeed, it is obviously intended rather for quick and ready reference than to give the student a comprehensive knowledge of disease. This method is unsuited to teaching the characteristics and behaviour of such a protean affection as tuberculous laryngitis, or to giving real help in the diagnosis of cancer of a vocal cord. The arrangement of the work naturally makes for dogmatism and for errors of statement. Of malignant disease of the tonsil it is said that extirpation by surgery or electrosurgery is imperative; treatment by radiotherapy, not mentioned here, is discussed in a separate section of the book. Killian's operation on the frontal sinus is recommended as the external operation almost universally employed; in this country it has been largely replaced by a limited opening through the floor of the sinus with removal of the fronto-ethmoidal cells. In the treatment of chronic laryngitis, potassium iodide in doses of 15 drops is advised.

These criticisms are called for. But the important thing remains that the work is exhaustive in scope, covering concisely almost every disease and lesion of the throat and nose; the technique of methods of examination and treatment is well described and illustrated, and there is a good index. While it is hardly to be recommended to the student desiring to gain his first general knowledge of the speciality, it will be useful to him, and to the practitioner.

THE LANCET

LONDON: SATURDAY, JANUARY 25, 1936

KING GEORGE V

ALTHOUGH the final illness of His Majesty KING GEORGE V. was brief the country had been acquainted by regular bulletins of the ominous nature of his symptoms. All must have known from the very onset, medical men and public alike, that the issue might be the gravest, taken in connexion with his serious illness of seven years ago. We then had laid before us, in regular and candid statements, the story of a brave man's struggle, now advancing, now decliping back, now reaching a point when victory might reasonably be expected, and now falling to the level when nothing but defeat could be anticipated. The story, then unfolded to us with pathetic clearness, none can have forgotten, and the wonder has been that the survivor of such an ordeal should have been able to face the responsibilities of a real and active monarch, one who lived up to his own ideal as father of his people. Great worker and great sportsman as the KING was he met with anxious conscientiousness his multifarious engagements despite his physical delicacy. He lived and he has died a great King, and not only is this the knowledge of his sorrowing subjects to-day, but it will be the certain verdict of posterity when the vast events of his reign are seen in their proper perspective. It is a fine and consoling reflection that the occasion of his jubilee offered a unique opportunity for a demonstration of genuine affection and admiration from all classes, and his last broadcast, put the seal upon those feelings of love which were felt for him as a man. The KING spoke, with obvious emotion, of the personal link existing between himself and his people. "I am thinking," he said, "not so much of the Empire itself as of the individual men, women, and children who live within it, whether they are dwelling here at home or in some distant outpost of the Empire." His closing words were: "I send to you all, and not the least to the children who may be listening to me, my truest Christmas wishes, and those of my dear wife, my children, and grandchildren who are with me to-day." The message was heard throughout the world, and drew for the millions who heard it a picture of the great ruler as one who cared for his subjects as a father.

KING GEORGE V. was born on June 3rd, 1865, at Marlborough House, and succeeded to the throne on May 6th, 1910, being crowned at West-

minster Abbey in June of the following year. He was the only surviving son of his father, an elder brother, the Duke of Clarence, having predeceased that father. For a brief period he made use of the ancient royal title of Duke of Cornwall, until, after a fitting interval, he became Prince of Wales. Before he was heir to the throne he remained a working officer in the Royal Navy; his record in the Senior Service was that of a capable and strenuous officer, and he never lost his deep love of the sea. There is no doubt that the devotion to duty and the *bonne camaraderie* which distinguishes the personnel of the Navy counted for much in the manner in which the KING met his responsibilities and filled his post as the National Chief, for rectitude, simplicity, and sympathy formed his daily expression of conduct. Assuredly in the dealings of his kingdom with other countries these plain characteristics of our ruler played an effective part. He may not have had the intimate knowledge of the Royal circles of Europe which made his father so conspicuous a figure in continental politics, but he was as free from party bias as KING EDWARD, and as firm in the times of political unrest prevalent at his accession to the throne as his father had been before him, as respectful to the constitution and to the authority of Parliament, and as sound in his knowledge of affairs. When all political dissensions became of secondary importance to the nation by comparison with the world issues in which the war involved the Empire, KING GEORGE, in public and private capacity alike, proved himself a veritable leader and example. He was throughout unsparing in his efforts, loyal to his advisers, and a sharer practically in the anxieties and privations of his subjects. Thus in the third period of his reign he reaped a splendid harvest of personal affection from his subjects who year by year and even day by day grew to have a better understanding of their KING. We all knew that he was a good man, and it must surely add poignancy to our grief to recall that this patriot in the largest sense had so intimate a love for England. The KING's love of England, English scenes, English sports, and his English domestic life endeared him to his subjects in a very particular sense. It has been well known to his medical advisers for some years past that he could have enjoyed more certain health and probably prolonged his days by spending the winter months at warmer and more sheltered places than his London or his Sandringham homes, but the KING remained in England not only from that sense of duty which made him the most serviceable of monarchs, but because the Norman castle, which gives to the Royal House its present name, and the heaths and marshes of Norfolk made an appeal to him more urgent than the balmier prospects of the continental health resorts could offer. He did not avail himself of climatic advantages which are only open to a small

proportion of his fellow Englishmen, and in their memory of him this will count.

To the profession of medicine KING GEORGE V. was always a sterling friend, and although his name is not associated, as is that of his father, with any medical movement of a significance comparable to the foundation of King Edward's Hospital Fund, it has been abundantly apparent that in deed as in will he realised the importance, in all the social history of to-day, which underlies medical service. And his deep interest in the voluntary hospitals of the country was manifested in the ægis which he extended to the voluntary hospital movement, where he carried on his father's work, and in the fact that during his reign it became an established tradition that members of the Royal Family should be heads of hospitals, and that the Royal Family should take part in a practical manner in all developments of medical charity.

THE CAUSES OF VARIATIONS

THE discovery and use of cabbages which would stand the winter in northern climates was an event of a sanatory importance comparable to that of the invention of vaccination against small-pox. When there were no winter greens available for man and no turnips or swedes to provide fresh meat, the population must have come to the early spring in poor trim, for scurvy and near scurvy must have been the common lot and dovecots were only for the few. The first flush of edible green in the countryside is still often welcomed by nibbling the hawthorn buds on the roadside though perhaps those who do it know the reason for their ritual as little as the cook knows why there should be greens of some sort every day. With his unerring instinct for what is good, man seized on the cabbage and has grown it in one form or another as universally as he has the potato, partly for himself and partly for his animals. And many varieties there are—spring cabbage, curly kale, cauliflower, brussels sprouts, kohlrabi, and the rest. All of them breed true to seed and with ordinary luck we can have kale or broccoli at will, which means that all this variation is due to germinal changes and not to environment or special methods of cultivation. They are all in fact sports, or as we say nowadays mutations, of the plain wild *Brassica oleracea* which lives here and there on our southern coasts and behaves in winter like any natural biennial plant.

And in the eighteenth century, along with the introduction of cabbages and turnips and the depopulation of dovecots, began the revolution of thought which led men to suspect that they lived in a moving world and not as they had supposed in fixed and settled surroundings which had nothing more to expect than the crack of doom. They began to see change and infer it and to be curious about its nature and causes. Their thoughts crystallised once about the origin of species and have crystallised again in this century from MENDEL'S discovery of unit characters and alternative inheritance. At the moment there is a pretty

general consensus of opinion that many of the features of animals and plants are primarily determined by specific particles in the chromosomes, and there is abundant evidence that the sudden heritable changes, which are always found if large populations of live organisms are closely examined, are due to changes in these genes. Mutation is a plain fact of nature, and there is no visible end to the possibilities which would be to hand if its occurrence could be brought under control. It would indeed be strange if people were not acutely interested in trying to discover the causes of germinal changes, in the hope of promoting good things such as brussels sprouts and of preventing evil things such as idiots. Our readers will therefore perhaps be interested in a paper which Mr. HAMSHAW THOMAS, F.R.S., of the Cambridge botany school, gave to the Linnean Society, printed in the last two numbers of *Nature*. The particular point which he discusses is the possible influence of the penetrating radiations known as cosmic rays which pour on to the earth out of space and take origin very possibly in the annihilation of matter. That this kind of influence can cause mutational change was established when MULLER obtained heritable variations by the action of X rays. But whether short wave-length radiations have any special action apart from their ability to penetrate cells and, by virtue of their small size, to injure only a limited part of a cell, is uncertain; it is perhaps generally true that if many cells are knocked about by any harmful agent a proportion of them will suffer only that particular local damage required to produce a mutation. Be that as it may, and admitting the probability that HARRISON brought about germinal changes by feeding caterpillars with poisonous salts, the influence of radiation is an attractive suggestion. Experiments in which animals have been more or less shielded from cosmic rays by being kept as far as may be in the bowels of the earth have so far given no clear answer; negative results of observations which are in the evolutionary sense of momentary duration are of no great weight. Cosmic rays are few and far between; many of any chromosomal injuries which they may inflict would be incompatible with life and in any case only a minute proportion of germ cells give rise to individuals sufficiently adult to show their characteristic features. Dr. HAMSHAW THOMAS appeals to evidence of another kind. It being known that the intensity of cosmic radiation increases greatly with altitude so that there is about ten times as much at 20,000 feet as at sea-level, he points out that there are many more kinds of plants on mountains than on plains, they they are more variable and include a larger number of peculiar local species. Thus Costa Rica, largely mountainous and only half the size of Florida, contains as many species of plants as the whole of the south-eastern United States; there are 60 varieties of wheat in Afghanistan and only 12 in Italy, and many more mountain than low-land species of primula, while several naturalists have remarked on the abundance of endemic species on mountains.

Of these facts there are obviously other possible explanations, but Dr. THOMAS's suggestion that an abundance of cosmic rays is responsible for an excess of variation needs further examination and, if possible, experiments on a large scale. If there is much in it, it would probably be apparent in a thorough study of the high Andes where there is a considerable human population, partly native, partly immigrant, which badly needs examination against the background of Western medicine. The question is one of great theoretical and practical importance, and it is perhaps not too much to hope for a more or less permanent commission to be established there to see what can be ascertained about the variability of men, animals, and plants, and to make a thorough study of the medical position there. It is true that cosmic radiation is not as abundant in Peru as it is further north, but the presence of a considerable indigenous population well outweighs this disadvantage. Man is far better known than any other animal, and careful observation should be able to determine whether he is more liable to mutations in the Andes, possibly also in Tibet, than elsewhere. And where man lives experiments can be made, though in this connexion where great numbers and long times are involved observation may be more likely to find an answer.

A NEW PUBLIC HEALTH CODE

THE statute book is, in CROMWELL's phrase, an ungodly jumble. More than any other department the Ministry of Health labours to remove the reproach. Not long ago the departmental committee, which it had appointed under the chairmanship of the late Lord CHELMSFORD, produced the admirable code which became the Local Government Act of 1933, re-writing in modern language and compendious form a mass of confused and overlapping enactments. And now the same committee, under the experienced guidance of Lord ADDINGTON, has produced another big Bill (Cmd. 5060; 3s. 6d.) which forms a draft code of the existing laws of public health. Overhaul of our health legislation was indeed overdue. The principal act of 1875, parent of a scattered progeny, was itself descended from acts of 1848 and onwards which it all too faithfully reproduced. Much has happened in Whitehall and in the countryside since those early years when panic over an epidemic of cholera was one of the chief motives of legislation. Prevention, and not merely cure, of disease is now the accepted policy. The individual's health is recognised as the community's concern. Slum clearance, water-supply and sewerage, maternity and child welfare, and school medical services are related parts of a national effort. Comparison of ancient and modern statistics of cholera, plague, and small-pox, typhoid, diphtheria, and tuberculosis, is a sufficient reminder of progress. In the statutory structure of public health over the same period the central and local authorities have been transformed. The Ministry of Health has replaced the Local Government Board of 1871. Boards of guardians

are gone. Popularly elected county councils, created in 1888, now form, with county boroughs, fewer and bigger units; with ampler resources, a wider outlook and a rational re-allotment of institutional facilities, they administer public health in the spirit of social service rather than of poor relief. A principal act of 1875 was hardly fit to govern such developments.

The departmental committee was directed not only to frame consolidating legislation, but also to consider what amendments would facilitate their work and would secure simplicity, uniformity, and conciseness. Fifty-year-old clauses will not stand literal reproduction to-day. The 1875 Act, for instance, contained no fewer than four differently expressed provisions as to power of entry. Pure consolidation would dictate the separate re-statement of each in the new code, but common sense will substitute one uniform provision for four. Elsewhere a handful of random examples will show the opportunity for unobtrusive modernisation. Section 134 of the 1875 Act enabled regulations to be made for speedy interment of the dead and house-to-house visitation in times of formidable epidemic. No such regulations have been made for many years, and the section can clearly be dropped. Nor is it necessary to reproduce Section 138 whereby poor-law medical officers and other doctors who attend patients on board ship (under regulations prescribed by Section 130) can recover charges from ship-owners; the provision is a dead letter. An enactment of 1907 forbade the connexion of drainage with a rain-water pipe; modern sanitary practice is against connecting a rain-water pipe with a sink; the new clause incorporates a restriction to this effect. The 1875 Act, as already noted, was itself framed out of a group of earlier statutes. Perhaps this is why it uses, without definition, sets of alternative phrases abhorrent to the modern draftsman. It speaks of "infectious disease," "fever or other infectious disease," "infectious disorder," "dangerous infectious disorder," and "dangerous infectious disease." The Customs Act of 1876 uses the phrase "highly infectious distemper." The Infectious Disease (Notification) Act of 1889 contains a catalogue, it is true, of specific "infectious diseases"; but the vocabulary of the acts is needlessly confusing. The new code uses simply the two phrases "infectious disease" and "notifiable disease." Incidentally, in re-stating the list of "notifiable diseases" from the 1889 Act, it omits to specify the fevers therein described as "continued or puerperal"; the "continued fever" was an old term, covering undiagnosed pyrexias, which is nowadays of little significance, and "puerperal fever" is left, for administrative simplicity as well as on medical grounds, to be governed by regulations such as those whereby in 1926 the Minister made puerperal pyrexia notifiable. On the whole the committee, composed of members with legal and administrative rather than medical qualifications, has refrained from stiffening the law in directions where medical opinion might have recommended it. The committee found its hands full enough without pursuing

medical questions. It leaves the general improvement of the law to future parliamentary effort.

The new code consists at present of 334 clauses. Had it dealt with every aspect of what might popularly be regarded as public health, a thousand might have been required and an unwieldy document would have resulted, with multiplied vulnerabilities. The project excludes housing, mental treatment, midwives, burial and cremation, building lines and open spaces, and those unrelated Home Office topics which have been grouped in public health acts of the past. It confines itself to strictly public health provisions in relation to the prevention and treatment of disease—i.e., as regards environment, the arrangements for drains and sewers, water-supply, buildings and the abatement of nuisances, and, as regards personal hygiene, arrangements for hospitals, maternity centres, and the like. The draft bill covers the Canal Boats Acts, the Baths and Washhouses Acts, the Maternity and Child Welfare Act, 1918, the Nursing Homes Registration Act, 1927, and the infant life production provisions which are the sole surviving part of the Children Act, 1908. Its plan and its limitations, and the details of its proposed changes, are set out with well-reasoned justifications in the blue-book (Cmd. 5059; 2s.) which accompanies the bill. One final word of

warning we respectfully add. Under technical parliamentary rules a bill which is purely consolidation cannot be amended. The process of consolidation with amendment is usually performed by framing one bill for consolidation and another for amendment, the latter being passed first and then swallowed up by incorporation in the former. This process was not adopted with the new Public Health Bill if for no other reason than that the separate amending bill would have been distracting in its complexity and unintelligible in its terms. As the new bill includes a modicum of amendment along with pure consolidation, it is open to any member of Parliament to propose further amendments. If such a right is exercised on a large scale, the bill is doomed, and all the disinterested labours of its expert authors will be lost. The same situation arose over the parallel Local Government Bill in 1933, but private members nobly refrained from sabotage and the code was successfully passed into law. Those who are not satisfied with the new public health code should hold their hands and effect their amendments by separate bills in the future. Amendment indeed will be far more easy once this clear code receives the Royal Assent. To choke it to death now by excessive alteration would be a crime against public health administration.

ANNOTATIONS

STAMMERING

ANY defect of speech is a serious handicap to a school leaver in search of employment. Stammering is far the commonest of speech defects; about one child in a hundred stammers, four times as many boys as girls. The stammer differs from other speech defects in two respects: under certain conditions no stammer is apparent, and it does not respond to the usual speech-training methods—suggesting that a stammer must be more than a mere defect of speech. Regarded as a speech defect it is essentially an interference with the coördination of the muscular articulatory mechanism, associated with some disturbance of respiration, particularly, according to Seth and Guthrie, of the synchronisation of thoracic and abdominal breathing. Its more obvious manifestations take usually one of two forms: the "clonic," popularly known as the stutter, in which the sound to be produced is repeated several times; and the "tonic" in which a silent period, long or short, precedes utterance of such sounds as give difficulty. The "tonic" form may be accompanied by spasmodic contractions of the muscles of face, lips, larynx, or even limbs, which appear to take the place of the articulatory contractions of the stutter.

Many theories of causation have been advanced, but there is a growing convergence of opinion to-day towards the view that stammering is in essence a neuropathic condition and as such therefore may be attributable to many causes. It cannot have escaped the observation of any students of the condition that stammerers are usually nervous children. A special inquiry¹ among Manchester school-children, initiated by Dr. H. Herd, revealed the frequency of neuropathic symptoms such as

excitability, irritability, abnormal fears, enuresis, night-terrors, nail-biting; 41 of 53 stammerers were of a very excitable type. These symptoms are not the result of the stammer, but are parts of the stammering syndrome. Stammering, then, is not merely a disorder of speech, but a disorder of personality, an emotional disturbance. Stammerers are, in fact, one type of "difficult child." As is shown in a Rochdale inquiry,¹ it is the child who lives in an "atmosphere of over-solicitude" whether through his place in the family, through illness, or other cause who, when some crisis (to him) occurs in his life—the arrival of a baby sister or brother, change of school or teacher, fright, loss of a parent, family disharmony—fails to adjust normally and may develop a stammer, just as he may develop asthma.² There may, in addition, be some inherited neuropathic tendency, difficult often, however, to separate from the environmental influence of a neuropathic parent.

Realisation of this wider aspect of stammering involves some enlargement of the scope of treatment beyond the mastery of vowels, of consonants, and their combinations. The methods of a child guidance clinic may have to be employed in order to deal with possible maladjustments and to elucidate the subtle psychological factors, if such there be. In the solution of these matters the parent and the teacher may have a large part to play. So far as the individual child is concerned, the first essential is the production of self-confidence; its lack is characteristic of the stammerer and the inferiority complex is most manifest in the presence of strangers. This defect must be steadily overcome by the suggestion of the teacher. Next in importance to suggestion is relaxation, the significance of which is apparent

¹ Quoted in "The Health of the School Child" (report of the C.M.O. of the Board of Education for the year 1934), p. 101.

² THE LANCET, Jan. 11th, 1936, p. 96.

from the tenseness of effort displayed by the stammerer in his struggles to speak. Natural speech should proceed in an easy flow. The act of speech should be more or less unconscious; there should be no sense of strain, no tensely contracted muscles. The habit of general muscular relaxation can be fostered by exercises alternating with short periods of complete rest. The older method of speech therapy involved a too intense concentration of effort on the production of sounds and contradicted the principle of relaxation. For this reason some authorities have dispensed with any specific speech training and have concentrated, if the use of the word is allowable, on relaxation. This treatment has been advocated and practised by the London education authority with considerable success under the control of Dr. E. J. Boome. The careless habits of speech, however, that many stammerers develop do justify some practice at least in correct speech in the form of reading along with others, or reciting in dramatic form, conditions under which a stammer naturally tends to disappear. Parents and teachers must cooperate if a satisfactory result is to be reached and retained; education authorities should modernise their methods of treatment in accordance with recent knowledge, invoking the help (see p. 225) which the Central Association for Mental Welfare offers.

SUPPLY OF BLOOD-GROUPING SERA

FOR an efficient and safe transfusion service it is necessary to determine quickly and accurately the blood group of prospective donors. In practice this requires stock sera against which the grouping can be tested, but so far the blood-grouping sera on the market have for the most part been unstandardised as regards potency, and the expense has militated against their general use. For these reasons it has been the custom of various independent laboratories to make their own stock blood-grouping sera from Group 2 (A) and Group 3 (B) individuals, any member of the staff, whose blood was of either group, being considered a convenient source of supply. The amount of isoagglutinins, the responsible factors in such sera, has not, with rare exceptions, been estimated. Dr. H. F. Brewer, medical officer to the British Red Cross Blood Transfusion Service, working on the blood donors of this organisation, has found a normal variation ranging from 1 in 2½ up to 1 in 800 in the titre of the α and β isoagglutinins in the sera of Group 3 (B) and 2 (A) donors respectively. Repetition at intervals of the titre estimations on batches of donors proved that the titre of isoagglutinin content for the serum of a particular donor is practically constant. A point of interest is that the average titre of the α isoagglutinin in Group 3 (B) serum is higher than that of the β isoagglutinin in Group 2 (A); this has also been pointed out by K. Kettel, and applies to the α and β isoagglutinins present together in the serum of Group 4 (O) individuals. The isoagglutinin titre of grouping serum gradually deteriorates with storage, and obviously the higher the initial titre the longer will be the period during which it can be used; a serum with an isoagglutinin titre of 1 in 200 will maintain a satisfactory potency as regards agglutination for a period of six months, even at room temperature. If the initial titre should be less than 1 in 25, it may deteriorate within this time to such an extent that it fails to clump red cells containing the homologous isoagglutigen, and an error in blood grouping will result.

In an attempt to make a supply of grouping sera

of high titre and of cheap price generally available throughout the country, the Red Cross Transfusion Service has arranged to provide free to Messrs. Burroughs Wellcome and Co. serum in bulk from Group 2 and Group 3 donors specially selected on account of their high isoagglutinin titre (1 in 200 or above); such serum will be put up in capillary tubes each containing about 0.1 c.cm. and packed by the firm mentioned at a cost just sufficient to cover expenses, and will be distributed from the Blood Transfusion Service, 5, Colyton-road, East Dulwich, London, S.E.22 (Tel.: Forest Hill 2264), to whom application can now be made. The price is 6s. per dozen pairs of capillary tubes if supplied to hospitals, medical practitioners, and provincial services affiliated to the London service; 12s. per dozen pairs to non-affiliated hospitals and others. Instructions about blood-grouping technique will be enclosed. The scheme should facilitate blood transfusion generally by rendering blood grouping more readily available and more accurate. At the present price it may be practicable for every medical practitioner and medical institution to keep a supply and replenish it when there is any risk of staleness. Undue calls on Group 4 (O) ("universal") donors should now diminish.

THE SURGERY OF THE SYMPATHETIC

A BRIEF report of the Tenth Congress of the International Society of Surgery appeared from a correspondent in THE LANCET of Jan. 11th.¹ In this report mention was made of the plea put forward by Prof. Archibald Young, of Glasgow, for the consideration of peri-arterial sympathectomy in properly selected cases, Prof. Young contending that though the discussion before the Congress was nominally restricted to the surgery of the lumbar sympathetic it would have been more profitable if it had been extended to include the results obtained by numbers of surgeons from peri-arterial operations in the limbs and on the inferior mesenteric artery, and also to review their experience of presacral neurectomy. He repeated the claims which he has formulated elsewhere for peri-arterial neurectomy which in his opinion had suffered undeserved neglect, stating that in his hands the operation had yielded satisfactory results in 65 per cent. of cases. Turning to lumbar ganglionectomy he stated that in his experience the operation had given excellent results in Raynaud's disease, and that more was to be expected of it in arteriosclerosis than in thrombo-angiitis obliterans. He had experienced striking success in a few cases of chronic arthritis and this encouraged him to advocate lumbar ganglionectomy though the patient may be bedridden. He also referred to the treatment of Hirschsprung's disease and of painful conditions of the bladder by operations closely allied to lumbar sympathectomy.

AVERTIN ANÆSTHESIA IN CHILDHOOD

EVIDENCE of the interest taken in Sweden in Avertin anaesthesia will be found in four papers published in *Nordisk Medicinsk Tidsskrift* for Dec. 21st. It was in August, 1932, that avertin was first adopted by the large children's hospital, Kronprinsessan Lovisas Vårðanstalt, and between this date and the end of October, 1935, it has been used in 1250 cases without mishap and with excellent results. Its administration in an enema saves the child from the struggling and the psychic disturbances which

¹We take this opportunity of mentioning that the official representative of the Royal College of Surgeons of England at the congress was Mr. C. H. Fagge.

sometimes follow the application of an ether mask to the face, and the profuse bronchial secretion evoked by ordinary ether anaesthesia is also avoided. Ether is not, however, totally dispensed with in this hospital, and a little is usually given (from 10 to 30 c.cm.) after consciousness has been lost under avertin. Dr. Einar Perman, who provides this information, states that avertin was first used only in exceptional cases and when lesions of the respiratory tract contraindicated ordinary inhalation anaesthesia. Its advantages, however, soon became so evident that it has now been adopted as the standard anaesthetic for children, who do not react to it with the psychic upsets occasionally seen in adults. Avertin is now used for all circumcisions and operations for hernia and mastoid disease. In many cases of empyema difficult to locate, the exploratory punctures as well as the operation itself are performed under avertin, which has also proved valuable for cystoscopic examinations. In another paper, Dr. Georg Bremer reports from the same hospital his observations on avertin anaesthesia in dentistry. He has found avertin the solution to the problem of the child under school age requiring unavoidably painful dental treatment. His experiences in this field since the beginning of 1934 concern two-score children and a couple of young adults whose mental condition would have been a contraindication to any dental operation carried out with only a local anaesthetic. The remaining two papers describe the treatment of tetanus with avertin—a method familiar in this country through the writings of L. B. Cole¹—and the temperature of the skin during avertin anaesthesia.

THE PHYSIOLOGY OF FERTILITY

RECENT analyses of population trends suggest that reproduction, not only in England and the rest of North-West Europe but also in other regions inhabited by Europeans, is proceeding at a dangerously slow rate, and that unless a pronounced increase in the number of births occurs before long, the relevant populations will be considerably diminished and their age constitutions greatly altered. In an address delivered to the Eugenics Society on Tuesday last, Dr. S. Zuckerman suggested that this fact puts a completely different complexion on the usual view that is taken of man's fertility. Even allowing for full working capacity, the human reproductive machine does not compare favourably with that of most other vertebrates, for even apart from specially designed contraceptive measures, many normal and pathological factors militate against a higher fertility. For example, the childbearing period in woman forms a relatively short part of her total life compared with that of most other mammals.

The normal limiting factors to the process of conception itself, said Dr. Zuckerman, are not conducive to a very high fertility. Ovulation both in man and in old-world primates, it is now believed, occurs at some time during the middle period of each menstrual cycle. Occasionally, too, and for reasons not yet understood, ovulation may fail to occur in otherwise normal menstrual cycles. There are no data regarding the viability of the ovum of any primate, but if investigations on lower mammals are any guide, the human ovum does not live more than a matter of some hours. Sperms are also short-lived, and unless the male and female gametes meet within a fairly brief critical period conception during any given cycle is impossible. Man and most of his

fellow old-world primates do not experience, as do most other mammals, a sharply demarcated oestrus which would ensure that insemination occurred at the most favourable time for conception, and it would almost seem that an increased frequency of coitus is the primate mechanism which replaces from this point of view the oestrus of the lower mammal. Discussion still continues on the question of the occurrence of a "safe period" in the menstrual cycle; the balance of clinical evidence seems to be in its favour. Dr. Zuckerman pointed out that in the absence of any available sign of ovulation in man, the further analysis of the "safe period" into its two components, the period of viability of the sperm and the period of viability of the ovum, is clearly impossible. Such an analysis is at present being conducted on monkeys which in their sexual skin cycles provide a clear external index of the occurrence of ovulation. The data so far collected do not provide any information on these two particular points, but clearly support the idea of only a limited period of fertility in each menstrual cycle.

DILATATION OF THE URETERS

A LEADING article in our last issue described some recent investigations into the cause of dilatation of the ureters during pregnancy. It appears that Traut and McLane¹ have also been studying the tone of the ureters during pregnancy using, like Baird, a modification of the hydrophorograph originally introduced by Trattner.² Their conclusions agree with those of most other workers. They found a definite atony of the ureters, beginning in the third month of pregnancy and reaching its peak in the seventh and eighth months. During the last month there seemed to be a definite return of muscular irritability as expressed by peristalsis and response to stimulation. They ascribe the dilatation of the ureters partly to the pressure of the gravid uterus and partly to this atony, which they believe to be due to some hormonal factor.

VITAL STATISTICS FOR 1935

THE Registrar-General has issued a provisional statement of the figures for birth-rate, death-rate, and infant mortality for the year 1935.

—	Birth-rate.	Death-rate.	Infant mortality-rate.
England and Wales ..	14.7	11.7	57
121 county boroughs and great towns, including London ..	14.8	11.8	62
140 smaller towns ..	15.1	11.4	55
London (administrative county)	13.1	11.3	58

The smaller towns are those with estimated resident population of 25,000–50,000 at the 1931 census. The birth- and death-rates for England and Wales as a whole are calculated on the estimated mid-1935 population, but those for the towns aggregates and for London are calculated on the estimated mid-1934 populations. The birth-rate is based on live births, the death-rate on crude deaths.

The birth-rate for 1935 is 0.1 per thousand below that of 1934 and is 0.3 above that of 1933, the lowest recorded. The crude death-rate is also 0.1 below that of 1934, the only years with a lower or similar record

¹ THE LANCET, 1935, ii., 246 and 256; Quart. Jour. Med., 1935, iv., 295.

² Traut H. F., and McLane, C. M.: Surg., Gyn., and Obst., January, 1936, p. 65.

³ Trattner, H. R.: Jour. of Urol., 1932, xxviii., 1.

being 1923 (11·6), 1926 (11·6), 1928 (11·7), and 1930 (11·4). The infant mortality-rate is the lowest recorded, the previous record years being 1934 (59) and 1930 (60). The rates are provisional and are issued for the information of medical officers of health, but they are not likely to require substantial modification.

TUBERCULOSIS IN HOSPITAL EMPLOYEES

THE investigations of Scheel and Heimbeck at the Ullevaal Hospital in Oslo have stimulated statistical investigation in other hospitals whose employees have shown a disquieting tendency to develop tuberculosis. The latest report¹ on this subject comes from the tuberculosis hospital of Söderby, Stockholm. Its medical superintendent, Dr. A. Gullbring, has found that between 1918 and the middle of 1935 there have been 45 cases of tuberculosis developing in a staff of 2016—an incidence of 2·2 per cent. While this rate was 2·6 per cent. (40 out of 1525 persons) among the staff in direct contact with patients, it was only 1 per cent. (5 out of 491 persons) among the administrative staff. Since 1928 new members of the hospital staff have been tested with tuberculin (Mantoux's test), and 20 per cent. of the 484 persons thus examined have been found to be tuberculin-negative. All the negative reactors tested at a later date showed a positive reaction. Of the tuberculin-tested employees, 19, or 3·9 per cent., have since developed tuberculosis, including only one belonging to the administrative staff. A comparison of the originally tuberculin-negative employees with the originally tuberculin-positive employees showed that the subsequent tuberculosis-incidence was 8·4 per cent. among the former and 2·8 per cent. among the latter—an observation confirmatory of the Scheel and Heimbeck teaching that the tuberculin-negative probationer is much more likely to develop tuberculosis. It may be noted in passing that in another Swedish hospital, the Serafimer Lasaret, the practice has now been adopted of inoculating with BCG those of the hospital staff who are found to be tuberculin-negative. Valuable data should, therefore, soon be available wherewith to control the claims made on behalf of BCG inoculation of tuberculin-negative nurses by the authors of the Ullevaal experiment.

RUDYARD KIPLING

RUDYARD KIPLING was in every sense of the word a patriot; all classes of society from the highest to the lowest recognised his deep devotion to our country and admired his heartfelt expressions thereof. That some could not go the whole way with him proves the difficulty that will arise always when the claims of fervent nationalism clash with the international spirit; but pause to any criticism is given here in Kipling's case by the tributes to his genius and to his fiery love of humanity paid by the press of the civilised world. Where Kipling will stand in the estimates of an extended future no one can say exactly, but he must long remain a great figure. And this position has been definitely allotted to him by the decision that he should be buried in the Poets' Corner of Westminster Abbey. Kipling was passionately poetical while replete with exact knowledge of many material things; he was deeply moving and quite slangy; he was a master of the English language and original, even unprincipled, in his use of it; he was a brilliant story-teller, the

most widely read poet of his day, and unsurpassed as a journalist.

It is fitting to record from his own lips his attitude towards medicine. In an address delivered to the students of Middlesex Hospital the following passage occurs: "Every sane human being is agreed that this long-drawn fight for time which we call Life is one of the most important things in the world. It follows therefore, that you, who control and oversee this fight and you who will reinforce it, must be amongst the most important people in the world. . . . In all times of flood, fire, famine, plague, pestilence, battle, murder, or sudden death, it will be required of you that you report for duty at once, go on duty at once, and remain on duty until your strength fails you or your conscience relieves you, whichever may be the longer period. This is your position. These are some of your obligations. I do not think they will grow any lighter." On another occasion, addressing the guests at a Hunterian banquet at the Royal College of Surgeons of England, he said: "Your dread art demands the instant, impersonal vision which in one breath, one beat of the pulse, can automatically dismiss every preconceived idea and impression, and as automatically recognise, accept and overcome whatever of new and unsuspected menace may have slid into the light beneath your steadfast hand. But such virtue is not reached or maintained except by a life's labour, a life's single-minded devotion." It was thoroughly characteristic of Kipling that the main thing which impressed him in the life of those who follow the calling of medicine was the claim made at all times and all places for the discharge of duty, for over and over again in prose and verse Kipling delighted to draw and extol the virtues of selflessness and resolution.

It is fitting for members of the medical profession, who know from experience the keen anxiety attached to the care of a patient whose cardiac reserve is slight and whose duties are onerous, to voice the gratitude of the Empire to Lord Dawson of Penn, on whom for eight years a heavy burden has fallen. It must have been due in no small part to his constant unobtrusive watchfulness as well as to his clinical wisdom that these years were for King George years of joyous fulfilment.

THE official proclamation of King Edward VIII. was made on Wednesday morning in pursuance with the Order in Council and in accordance with precedent. The proclamation was first read by Garter Principal King of Arms at the balcony in Friary Court, St. James's Palace, when a procession was formed and, flanked by the Royal Horse Guards, moved by way of the Mall and the Admiralty Arch to Charing Cross where the proclamation was again read by Lancaster Herald. On the site of Temple Bar a barrier marked the boundary of the City of London and at the corner of Chancery-lane the proclamation was read for the third time after formal admission to the City with the Lord Mayor in attendance. The procession then proceeded to the Royal Exchange where the proclamation was read for the fourth and last time.

KENT COUNTY OPHTHALMIC AND AURAL HOSPITAL. The extensions to this hospital, which was founded at Maidstone in 1847, are being opened to-day, Jan. 24th. A debt of £10,000 on the new aural wing which was opened in 1930 has still not been cleared and the hospital now carries a total debt of £15,000.

¹ Nordisk Medicinsk Tidsskrift, Jan. 4th, 1936, p. 14.

THE KING'S LAST ILLNESS

The following statement is based on authority :—

“THOUGH it is understood that for some weeks His Majesty KING GEORGE'S health had not been altogether satisfactory the KING was able to go out and in fact rode on his pony for a short time on Wednesday, January 15th. On Thursday, the 16th, the KING showed signs of a mild catarrh which soon began to abate. The ‘disquiet’ expressed in the bulletins of Friday and Saturday arose from evidences of cardiac insufficiency. The margin of cardiac reserve has in recent days been narrowing. This illness therefore arose from within and was in the nature of a culmination. It was thus not comparable to the invading streptococcal septicæmia localising at the base of the right lung from which KING GEORGE suffered eight years ago. It is true that that illness placed heavy burdens on the heart which may have had a causal relationship to this last illness. It is a remarkable achievement that KING GEORGE recovered from septicæmia and reigned over his Empire seven years through times which have been eventful and sometimes anxious.

“This last illness showed that the body carried through its work till its powers were ended and then came to rest after an illness short, and peaceful in its close.”

HIS MAJESTY KING GEORGE V. BEING RECEIVED BY SIR AUSTEN CHAMBERLAIN,
CHAIRMAN OF THE GOVERNING BODY, ON THE OCCASION OF THE OPENING OF
THE BRITISH POSTGRADUATE MEDICAL SCHOOL ON MAY 13TH, 1935.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXV.—THE PROGNOSIS IN DEAFNESS

II

(Concluded from p. 160)

Otosclerosis

THERE remains for consideration among the varieties of deafness attributable to lesions in the middle ear the important group of cases classed as otosclerosis; this is more common in females, is frequently hereditary, and is characterised by formation of new bone on the inner tympanic wall occluding the fenestræ, and, clinically, by the signs of middle-ear deafness with, at first, a strongly negative Rinné, good or increased bone-conduction, and marked loss of low tones, with a normal drum and Eustachian tube. Later there is often degeneration of the internal ear, but these patients, like other sufferers from middle-ear disease, rarely become completely deaf. Here, too, progress is not downwards along an even slope, but there are long stationary periods, often with a step down as the result of an illness, and sometimes an improvement with betterment of the general health. It happens not infrequently that otosclerosis is associated with some degree of chronic catarrhal otitis; in these cases attention to the hygiene of the nose, throat, and Eustachian tubes may be expected to give some improvement of hearing. Pregnancy has a peculiarly bad effect; although the hearing tends to improve again after delivery, it usually remains at a lower level than before, and it is sometimes advisable to induce abortion. Many forms of treatment have been tried and abandoned. A few otologists recommend a method of treatment by sonorous vibrations, introduced by Zünd-Burguet, in this affection as well as in chronic catarrhal otitis, but the results appear to be evanescent, and it has not been generally adopted. The late Dr. Albert Gray has employed weekly injections of thyroxine through the membrane into the tympanum with some encouraging results. Of surgical measures one, which holds out a faint hope for the future treatment of otosclerosis and of severe fibrotic occlusion of the fenestræ, consists in opening the bony labyrinth at the external semicircular canal, or in the region of the fenestræ, and covering the fenestration so made with a thin graft. In this way the hearing has certainly been improved, but there has been much tendency to relapse, due probably to the difficulty of keeping the opening patent and the graft from becoming rigid. Perhaps more lasting results may be obtainable by modification of the technique, but it must at present be acknowledged that no treatment has as yet any proved and lasting effect on the progress of this disease.

Nerve-deafness

This includes deafness caused by lesions of the labyrinth, the auditory nerve, or the nerve-paths to the brain, and is irremediable in a large proportion of cases, though not in all. Certain drugs cause deafness of this type; of these quinine and salicylates are the most important, and cause tinnitus at the same time. The hearing recovers when the drugs are withdrawn, but permanent impairment may follow continued large doses of quinine. Lead, mercury, and carbon disulphide may all produce deafness, while excessive use of alcohol and tobacco have a deleterious effect. Many instances of severe deafness following the administration of the salvarsan group

of drugs have been recorded; when syphilitic nerve-deafness is present salvarsan should be withheld until it has responded to mercurials. *Syphilis* causes nerve-deafness by affecting the cochlea and auditory nerve, and by producing basal meningitis; it may appear as early as the secondary lesions or as late as the development of tabetic symptoms. Improvement may follow early and thorough treatment, but often the disease progresses rapidly, and sometimes to complete loss of hearing; congenital syphilis is one of the commoner causes of deaf-mutism. *Epidemic cerebro-spinal meningitis* is accompanied by nerve-deafness with a frequency which varies in different epidemics from 4 to 30 per cent. and is a common cause of deaf-mutism; it is usually permanent but occasionally the patient recovers. *Toxic deafness* is common in enteric fever, but disappears during convalescence. Nerve-deafness is a rare complication of mumps; it is complete and incurable but, fortunately, usually unilateral. Measles, also, beside causing the common middle-ear infections, is an occasional cause of incurable bilateral nerve-deafness, probably of meningitic origin. Myxœdema has a bad effect on the hearing; any form of deafness in patients with hypothyroidism may be improved by thyroid extract. The patient with deafness resulting from traumatic *concussion* frequently recovers within a few days or weeks, but any impairment remaining after that time is likely to continue. The deafness due to fracture of the base of the skull is, of course, permanent.

Occupational deafness from prolonged exposure to noise is common in certain callings, such as riveting or machine-gunning; when established, it tends slowly to advance in spite of removal from the cause, and is only curable by change of occupation at an early stage. The single loud sound of an exploding shell was a frequent cause of deafness during the late war; improvement usually occurred during the first few weeks but some degree of deafness often remained. Allied to this is the condition called "*shell-shock*" deafness, the victim having been in action or buried by an explosion and becoming and remaining totally deaf. Probably he will have been deafened by labyrinthine concussion which recovered, but a psychic deafness persists. In such cases the hearing can be restored by appropriate psychiatric treatment, but it is difficult to distinguish sufferers from psychic deafness from those who have received organic damage of the cochlea. It is usually held that there is a probability of a physical lesion if the vestibular reactions are greatly diminished, but that the deafness is functional when these are approximately normal. True *hysterical deafness* is uncommon; it may be suspected when responses to testing are anomalous and, though it is curable, it may prove very obstinate. *Senile deafness* is a degeneration of the internal ear, characterised by relatively greater loss of the high notes, and of sharp sounds, such as the tick of a watch, compared with the continuous tone of a tuning-fork; it may begin prematurely at any age over fifty, especially in males. All deafness in old people is not, however, necessarily due to their age; they may suffer, like others, from cerumen or Eustachian catarrh, amenable to treatment.

Hearing Aids

Hearing aids have a bearing on prognosis in that they make conversation possible for many sufferers

from advanced deafness. Those with middle-ear deafness can always be helped by such means so long as secondary degeneration of the cochlea is not serious; hearing aids are therefore most useful to patients with middle-ear deafness, especially otosclerosis, who have good bone-conduction, and for them the more recently introduced electric aids with bone-conduction receivers are particularly suitable. It is generally possible to tell these patients that they will remain able to hear conversation by

means of a suitable apparatus. On the other hand, severe tinnitus is apt to be made worse by the use of electric aids, and these are in general less suited to patients with senile deafness than is some form of trumpet or, for the severest forms, the old-fashioned conversation-tube.

HAROLD BARWELL, M.B., F.R.C.S.,

Consulting Surgeon for Diseases of the Throat
and Ear to St. George's Hospital.

SPECIAL ARTICLES

TRACHOMATOUS CONJUNCTIVITIS ITS SURGERY AND PATHOLOGY*

BY A. F. MACCALLAN, C.B.E., M.D. Camb.,

F.R.C.S. Eng.

PRESIDENT OF THE INTERNATIONAL ORGANIZATION AGAINST
TRACHOMA; OPHTHALMIC SURGEON IN CHARGE OF
OUT-PATIENTS, WESTMINSTER HOSPITAL

DURING the last thirty years trachoma has become a comparatively rare disease in London. Ophthalmologists can realise with difficulty that the stigmata of the disease are borne by as many as half the inhabitants of the globe. For it is practically universal among the Mongolian and Semitic races, and among the Red Indian tribes; it is also widely spread among the Caucasians of India, and among the Malaysians. Nevertheless, our knowledge of the aetiology of trachoma is incomplete; the clinical diagnosis may be impossible in the absence of bulky and expensive apparatus, and no aids are to be obtained by means of chemical or microscopical tests; while the treatment has not improved during the last thirty years.

Pathological Anatomy

The response to attack by the virus of trachoma is a generalised flooding of the subepithelial tissue of the conjunctiva with lymphocytic cells. Typically, there are in addition special aggregations of these cells, which have been called follicles; however, in some cases no such follicles are to be differentiated from the general exudate of lymphocytes (Mikhail). The follicles, when present, differ in no way from similar aggregations of cells which appear in the condition known as follicular conjunctivitis. The conjunctival epithelium first proliferates, and then becomes villous; or it ulcerates and becomes replaced by scar-tissue epithelium.

The numerous underlying sebaceous or meibomian glands are at first affected by simple blockage of ducts and dilatation, the result of pressure by the cellular infiltration. Later the ducts become strangulated by the developing connective tissue, which begins to take the place of the lymphocytic exudate. The result is the appearance on the surface of the conjunctiva of numerous bleb-like excrescences, which burst on pressure, giving vent to gelatinous matter, the retained secretion of the sebaceous glands, with numerous cells. These bleb-like excrescences by all trachomatologists up to the present time have been looked upon as the follicles, described above, which have become dilated. There is no evidence that such dilatation occurs, nor has anyone ever observed such a phenomenon to develop. It

would be impossible for such a metamorphosis of the follicles to occur. Mikhail also has observed the dilatations of the ducts of the meibomian glands, but has not connected them with the bleb-like excrescences of the second stage of trachoma.

The whole process, for the description of which I am indebted to Pulvertaft, is a chronic progressive inflammatory change, almost certainly due to a secondary infection of the subepithelial tissues, following a primary epithelial lesion. The difference between other forms of conjunctivitis and trachoma is that the effect of the virus is much more lasting in trachoma, leading to this enormous subepithelial exudate, which penetrates to the tarsus, and via the fornical conjunctiva to the upper corneal limbus. The natural end of this severe exudate is its transformation into cicatricial tissue, thereby differentiating trachoma from other forms of conjunctivitis. The involvement of the tarsus in the cellular exudate, and the subsequent cicatrization which occurs, leads to thickening of this boat-shaped structure, and so to entropion. The trichiasis which accompanies the entropion is due to the development of supernumerary lashes by offshoots from existing hair follicles. This new development is caused by the hyperæmic condition of the lid margin which always occurs in serious cases of trachoma.

The hypertrophy of the superficial conjunctival epithelium leads to the appearance of numerous polygonal areas, which form a papillary hypertrophy. This is the result of irritation and is present in all forms of long-continued inflammation of the conjunctiva.

PANNUS

The term pannus was originally applied to the cloth-like opacity which the cornea of an inveterate case of trachoma exhibited. Completely ignorant of the pathology of the disease the surgeons of a former day used to attempt its removal. We now understand the term pannus to apply to an infiltration of the clear cornea by a cellular exudate, which is accompanied by the vascularisation of a previously avascular tissue. This may be observable only by optical magnification, or may be obvious to the naked eye. Following the primary epithelial lesion of the conjunctiva by the trachoma virus, whatever its nature may be, there is an infection of the subepithelial tissues to which response is made by a widespread inflammatory exudation. This spreads from the site of origin, near the retrotarsal fold, to the fornix, travelling beneath the epithelium, and from the fornix proceeds to the upper part of the limbus of the cornea. In this area pannus appears, which in early trachoma is the only pathognomonic sign of the disease.

Mikhail has made it quite clear that the changes at the upper corneal limbus occur in this way, and

* Abstract of a Hunterian lecture delivered at the Royal College of Surgeons of England on Jan. 17th, 1936.

cannot therefore be exercised in endeavouring to achieve this end.

General Principles of Bacteriological Grading

Since the taking of representative samples is difficult, since the results of any one sample are affected largely by the time-temperature conditions under which it is taken and held, and since atmospheric temperature plays a very important part in determining the number of bacteria present, it is concluded that the cleanliness of the milk of any given producer should be judged, not on the basis of one or two samples taken at some particular season, but on samples taken frequently and regularly throughout the year. Whatever test is used, separate standards should be laid down for summer and winter, and penalisation should not be practised so long as a given proportion of samples, such as 75 per cent., conform to these standards. What is required, therefore, for the routine bacteriological grading of milk is a simple inexpensive test, with a small experimental error, which can be used on a large scale by relatively unskilled workers.

Bearing these general principles in mind, it is concluded that, though undoubtedly of use for certain special purposes, neither the sediment test, the leucocyte count, the titratable acidity, the H-ion concentration, the increase in acidity, the bromthymol blue test, the keeping quality test, nor the laboratory pasteurisation test can be regarded as suitable for the routine grading of milk.

THE COLIFORM TEST

None of the three premises on which the use of this test for the control of water-supplies is based holds good for milk. With the possible exception of its employment on empirical grounds for Certified milk, there seems, therefore, to be no justification for the use of either the coliform test or the *coli-aerogenes* ratio test in the grading of raw milk.

For pasteurised milk, on the other hand, the coliform test may be of some value. It may serve as an index of the efficiency of the processing, if performed on freshly pasteurised milk, or as an index of the subsequent contamination or exposure to unsuitable temperatures, if performed on the bottled milk at the time of delivery to the consumer. The experimental error of the test is, however, very large, and on this account the results should preferably be reported, not in absolute numbers, but as above or below an arbitrary standard.

THE BREED SMEAR METHOD

This method has not received in this country the attention it deserves. It is in the rapid grading of milk that the method finds its greatest value. There is no other test that enables a differentiation between clean and dirty milks to be made so rapidly—within a few minutes—and the test is, therefore, of inestimable service at collecting stations where milk from individual farms is bulked preparatory to dispatch to the large towns in rail or road tanks. The test is of considerable assistance to farm inspectors and agricultural advisers, because it so frequently enables a distinction to be drawn between the various faults of production to which any given milk is subject. It can be used as a control to the plate count, or as a substitute for it. As a general test, however, for the routine examination of large numbers of milks, the Breed smear method is, we believe, less suitable than the modified methylene-blue reduction test that we have described.

THE PLATE COUNT TEST

Ostensibly this test measures the numbers of bacteria in milk, but in fact it does not. On account of the difference between various species of bacteria in their nutritional, respiratory, and temperature requirements, on account of the fact that many organisms may be dead, and most important of all on account of the gross irregu-

larity in the distribution and clumping of the organisms in the milk, the plate count merely registers the number of bacterial units capable of multiplying under the particular conditions selected. Since the average number of bacteria per clump is variable from one milk to another, and from time to time in the same milk, and since these clumps may disintegrate to a quite uncontrollable extent during the process of dilution, it follows that the figures yielded by the plate count are arbitrary, not strictly comparable from milk to milk, merely approximate, and have no real significance.

The technique is complex, is difficult to standardise, and requires highly skilled workers. Even under favourable conditions, with the method standardised as far as possible, the experimental error is very large, and on any one count an allowance of ± 90 per cent. may have to be made. Even this margin of error will not include all results. Besides demanding costly apparatus and a delay of at least two days in the result, the plate count seems to afford no better index of the sanitary conditions of production or of the keeping quality of the milk than the Breed test or the modified methylene-blue test. It is therefore recommended that the plate count test should be discontinued as a method of grading ordinary raw milk. Even for Certified milk it seems to have no advantage over the modified methylene-blue reduction test.

The quantitative expression of the results in figures extending over a wide range affords a fictitious appearance of accuracy which leads, not only in laymen, but even in public health officials, to a wholly unjustifiable feeling of confidence in their value. If the plate count is to be used, it should be permitted only on one condition—namely, that the results are reported not in quantitative terms, which are often grossly misleading, but as above or below an arbitrary standard.

For pasteurised milk, with the possible exception of Grade A pasteurised, the plate count is not recommended. The actual count on pasteurised milk is determined by so many factors independent of the efficiency of the processing that the results bear little relation to any important quality of the milk.

THE MODIFIED METHYLENE-BLUE REDUCTION TEST

This test seems to fulfil most of the requirements demanded of a test for the routine grading of raw milk. It is a simple inexpensive test, with a very small experimental error, which can be carried out by relatively unskilled workers on large numbers of samples, which demands a minimum of equipment, which can classify milk on the basis of cleanliness into the maximum number of grades desirable, and which affords on the whole a very good index of the keeping quality of the milk. Besides these advantages, it gives more information about the milk than does the plate count. The result does not appear to be seriously affected by the degree of aggregation of the organisms in the milk, and the test is a very much more sensitive index than the plate count of bacterial growth. By the use of the modified methylene-blue reduction test it should be possible to examine the milk of every farmer at weekly or fortnightly intervals throughout the year at a cost only a fraction of that of the plate count.

Whether the test is suitable for the examination of freshly pasteurised milk is doubtful, but there is reason to believe that it could well replace the plate count on bottled samples delivered to the consumer.

Recommendation

Whatever test is used, the report recommends that no attempt should be made to divide milk into more than three or four classes. The numbers and activity of micro-organisms in milk are determined by so many different factors that the establishment of numerous subdivisions is not only meaningless, but may be definitely misleading. From the public health point of view probably only two divisions need be made on the basis of cleanliness—namely, into (a) milk that is suitable and (b) milk that is not suitable for human consumption in the liquid state.

After consultation with the Ministry of Health the Medical Research Council has accepted Prof. Wilson's report as a statement of the scientific evidence on which possible administrative action may be based.

MORTALITY FROM PHTHISIS IN YOUNG ADULTS

A STATISTICAL STUDY

THE Registrar-General's mortality statistics for recent years have revealed an unfavourable trend in the death-rate from respiratory tuberculosis at young adult ages. In the enormous decline that took place in the death-rate from this cause during the latter half of the nineteenth century young adults had their full share, or even somewhat more than their full share. But between 1901-10 and 1930 the mortality at these ages has declined amongst males at a slower rate than is apparent in any other age-group, while amongst females there has actually been a slight rise in mortality at ages 15-25, and at ages 25-35 the decline has been appreciably less than that observed in any other age-group. Division of England and Wales into its administrative areas shows that it is in the highly urbanised areas that this unfavourable change is most apparent.

The basic figures illustrating this trend were set out in a paper read before the Royal Statistical Society on Jan. 21st by Mr. A. Bradford Hill, D.Sc., in which the author discussed various explanations of the present position. Some workers—e.g., F. J. H. Coutts—believe that the prodigious fall in the general death-rate from tuberculosis has led to a much lower level of infection in early life and this to a decline of immunisation in childhood, with the result that more persons must face the hazards of adolescent life with no acquired immunity. A more frequently accepted explanation attributes the relatively high mortality, especially of young adult females, to the entry of such persons into the "strain and stress of competitive wage earning," with the associated changes in their social life. Dr. Hill is unable to find much statistical support for either of these two hypotheses. Taking the death-rate from tuberculosis at ages 0-5 as a measure of the pressure of infection in childhood, he finds that the course of this death-rate in a group of English counties is not related to changes in the mortality experienced at young adult ages in later years. Similarly, towns with a high death-rate from tuberculosis at ages 0-5 do not appear to have a lower phthisis death-rate in young adult life fifteen to twenty years later than towns with a relatively low death-rate in childhood—general health factors being as far as possible equalised. With regard to occupational changes Dr. Hill shows first that in towns where the death-rate of young adult females has shown the greatest increase, there has been, on the average, a tendency for the rate of young adult males to increase also, or to show a slower rate of decline than in other towns. Where the female rate has declined substantially the male rate has also, on the average, declined substantially. Dr. Hill argues that this relationship implies a causal factor common to both sexes and suggests that the occupational changes in female life are therefore unlikely to be more than a partial explanation. He finds no correlation between changes in the volume of female employment over the years 1911 to 1931 and changes in the phthisis death-rate of young

adult females in the county boroughs. The changes in *type* of employment evident in recent years are more difficult to measure but the evidence available does not implicate such changes as a responsible agent.

Failing to find support for these explanations Dr. Hill turns his attention to the question of internal migration and the consequent distribution of young adults in different parts of the country. In past years one striking aspect of the phthisis mortality of young adults in this country has been the *higher* death-rates registered in the rural areas as compared with the urban areas, a phenomenon observed only at these ages. In an investigation carried out by the author some years ago,¹ he concluded that the explanation of this position lay in the migration of young adults from the country to the town, and that the migrants form a physically select group, which strengthens the town population at young adult ages and leaves a physically weaker residue behind. It follows that changes in the volume of this migration would be expected to produce changes in the regional distribution of the phthisis death-rate. In fact, in recent years the excess mortality at the young adult ages in the rural areas has completely disappeared. At the same time the loss of population in the rural areas has turned to a gain. The rural exodus slackened at about the turn of the century, while, in addition, the population of many rural areas may have changed in type due to the improved methods of transport enabling persons to reside in such areas and work elsewhere. Similarly the migrants to towns may have changed in type—for instance, it appears that London tends now to recruit young adults from the depressed areas rather than from the rural areas. Are these changes in the movement of population related to the changes in the phthisis death-rate? Dr. Hill finds that, to some extent, they are. Those county boroughs which have attracted young adults have, on the average, shown a declining death-rate from phthisis in young adult life during the past decade, while those that have lost population have tended to show a rising death-rate. This association might, the author suggests, be due to the fact that towns that have ceased to attract population are in a less satisfactory economic position than those that still recruit young adults, and this lower economic level is reflected in their death-rates. Alternatively it may be that, in towns that are no longer recruiting physically fit young adults from the rural districts, the death-rate is now measured upon a physically different population from that of past years. The towns are no longer strengthened, or are less strengthened, by this selective recruitment, the rural areas are less depleted.

Naturally, as we are dealing with a general phenomenon, Dr. Hill does not put this forward as being more than a contributory factor. In the recently issued text volume of the Registrar-General's Statistical Review for 1933, attention is directed to the association of increasing mortality at young adult ages with unfavourable housing standards.

"Grouping together areas with over 1 per room average density, phthisis mortality of females aged 15-25 increased from 1911 to 1930-32 by 25 per cent. in the county boroughs and 21 per cent. in the counties, whilst in London with a mean density about 1 per room it increased by 16 per cent. At densities of 0.85-1 per room the towns showed no change and the counties an increase of

¹ Med. Research Coun., Spec. Rep. Series No. 95, London, 1925.

15 per cent., but at densities below 0.85 per room both showed improvement of the order of 20 per cent. On the other hand, at ages 25-45, the fall in mortality was not confined to the better housed areas, but occurred almost irrespective of density."

It will be realised that the problem is intricate and its solution involves, as a first step, the clear presentation and careful analysis of statistical data. Dr. Hill's paper is a model of such work and will be indispensable in further study.

THE ARMY IN 1934

THE Report¹ of the Director-General of Army Medical Services for 1934 makes cheerful reading. Soldiering in that year was an even healthier occupation than in 1932, previously a record year. The ratio of admissions to hospital fell to 402.6 per thousand compared with 412.5 per thousand in 1932, and there were appreciable reductions in the death, invaliding, and constantly sick ratios. The most notable decrease in disease was that of the malaria-rate in India which fell to 67.5 per thousand.

Among officers the admission-rate was 191, a slight increase on 1932. The most important causes of illness were, in order, inflammation of areolar tissues and tonsils, fractures, dysentery, malaria, influenza, and appendicitis. The principal causes of admission to hospital were the same for the soldier as for the officer, except that for the soldier venereal disease appears in the third place while dysentery and appendicitis were less common than sprains, contusions, and inflammations of the upper respiratory tract. Bacillary dysentery is now about five times as frequent as amoebic—a marked contrast to the position ten years ago. Treatment is very satisfactory; only three patients were invalided from the Service during the year. There has been a striking decrease in the enteric group of fevers, especially in India. Arrangements are being made to extend protective inoculation to children, among whom the incidence is still too high. Improved figures in India are also responsible for a general reduction in sand-fly fever. There has been a general decrease in venereal disease, except in Jamaica. Work on the treatment of gonorrhœa tends towards substituting saline irrigation fluids for potassium permanganate. Specific infectious fevers were rather bad during 1934 and there were three deaths from diphtheria and two from scarlet fever. General immunisation of children at Black-down may have accounted for the complete absence of diphtheria on that station, and vigorous steps are being taken to spread this form of protection. The large increase of cerebro-spinal meningitis in the Indian civil population has not so far affected the troops. There was a high incidence of middle-ear disease in Jamaica, Malaya, and Egypt, probably associated with the fact that bathing is a chief recreation in these places. The reduction of tonsillitis is deemed to be of the utmost importance because heart disease of rheumatic origin is the cause of much wastage.

There has been a steady increase during the past 11 years in gastric and duodenal ulceration, and a smaller increase of appendicitis. The figures are believed to depend on improved diagnosis rather than on any real increase. There has been no change in the standard diet, but the ætiological factor of dental sepsis is under increasingly better control.

Young unmarried soldiers with ulcers which relapse twice after adequate medical treatment are being recommended for discharge. It is felt that young soldiers are liable at any time to military duties which may, and often do, nullify in a few days the results of the most careful treatment. Few of the factors important in maintaining freedom from ulceration are within the control of the individual soldiers themselves. While the best possible diet and cooking are provided, the men cannot always be kept from sudden exposure to fatigue or inclement weather or obtain, out of hospital, frequent regular meals specially adapted to their needs. Married non-commissioned officers of long service suffering from ulcer are, if possible, retained and the commissioned officers—apart from mobilisation or prolonged manœuvres—are in a more hopeful position.

The typhus group of fevers is attracting special attention abroad and evidence is accumulating to show that in India there are several hitherto unrecognised sub-groups with differing serological attributes.

SURGERY

There was an increase in the number of surgical operations performed during the year, the total being 9157, with a mortality-rate of 0.54 per cent. This includes pensioners and women and children. The chief facts that stand out from the Report are the importance of local injuries and diseases of the areolar tissues—notably boils and carbuncles. The latter are treated conservatively with magnesium sulphate compresses rather than by active interference. There is also a tendency to give up open operations on fractures and to rely more on skeletal traction by wire or pins. Local anæsthetics are more widely used for setting fractures. The use of spinal anæsthetics and Evipan is on the increase, although inhalants are still by far the most popular. The commonest major operations, apart from hernia, appendicitis, and ulcer, were cholecystectomy and for intestinal obstruction. There were 349 operations for recent inguinal hernia and 8 for femoral hernia. Injuries of the knee-joint played a fairly large part in disability and in 36 cases the fluid was aspirated; the time spent in hospital was considerably less than if the cases were treated by elastic pressure and conservative measures. "Out-patients" forms a very important part of the work of the surgical specialist, and clinics for the injection treatment of varicose veins and hæmorrhoids continue to be of great value. There has been a large increase in the work of radiological, massage, and electrotherapeutic departments.

WOMEN AND CHILDREN

There was an average strength of 18,508 women for which the Army Medical Department provided services during 1934, and of these over 3000 were admitted to hospital during the year. The principal causes of admission were abortion, cramp and spurious labour pains, malaria, and appendicitis, followed in frequency by inflammation of the tonsils, bronchi, and areolar tissue. In addition, 2660 women were admitted to hospital for confinement and 13,845 received out-patient treatment. Of the 29,521 children on the roll there were just over 5000 admissions to hospital and 26,847 out-patients. The principal causes of admission were enlargement of the tonsils, scarlet fever, inflammation of bronchi and tonsils, pneumonia and measles, dysentery, diarrhœa, malaria, and inflammation of areolar tissue. The wives and children are not entitled to medical

¹ Report on the Health of the Army, 1934. H.M. Stationery Office. Vol. lxx. 1p. 165. 3s.

attendance at public expense but are eligible for it under certain conditions. Military family hospitals are established at stations where the strength of the garrison is out of proportion to that of the civil population. All these hospitals have antenatal clinics and during 1934 more than 300 expectant mothers were admitted for observation and treatment. The percentage of abnormal labours was very small; the morbidity-rate was less than 8 per cent. and the mortality-rate 0.3 per cent. Authority is being sought for the extension of facilities for dental work by the Army Dental Service to all expectant mothers. An increasing interest is being taken in mother and child welfare, and accommodation is becoming cramped, but neither authority nor funds exist at present for new construction.

The Report emphasises the immense value of the work of the nurses of the Soldiers', Sailors', and Airmen's Families' Association. As an example, in Egypt seven nurses are employed, and they paid just under 40,000 visits during the year and gave an average of 514 hours' work each to welfare centres and medical inspection rooms. During the autumn a general supply of milk was instituted for children attending army schools in the Southern Command. Unfortunately there was some doubt for a time whether the Milk Marketing Board's scheme was applicable to army schools, but the hope is expressed that it will soon be possible to continue the sale of milk at reduced rates. In the Aldershot Command a manufacturing firm has offered to supply a third of a pint of malted milk for each child at a cost of 3d. a week. Fresh milk-supplies remain variable and only partly under control.

Most barracks in Egypt are very heavily infested with bugs, and an experimental disinfestation with hydrocyanic gas proved to be extremely satisfactory.

Research work has been continued on the effects of a new type of deep breathing exercises on the vital capacity of the lungs. The average gains of platoons on these exercises was 130 c.cm. greater than the gain of those on ordinary exercises. The research department of the Directorate of Pathology has been concerned with the production of a better typhoid vaccine. The demonstration that a typhoid septicaemia could be induced in mice, which could also be rendered more or less immune by vaccination, offered a new avenue of approach to the problem. It was found possible to enhance the virulence of different strains and the corresponding vaccine by continued and rapid animal passage. A similar procedure was followed for the paratyphoid organism, and it is confidently expected that vaccines prepared from the highly virulent cultures will be as superior in human prophylaxis as they are for laboratory animals; they were first used just before the trooping season of the year under review. Although inoculation is entirely voluntary, 98 per cent. of the troops availed themselves of it. Children from the age of 2 years upward tolerate the vaccine well.

The rate of rejection of the troops was nearly 40 per thousand lower than in 1932-33. It is hoped in future to maintain statistical records of those rejected at sight by the recruiting staff without medical examination, in order to obtain a true picture of the physical state of the youth of the nation. In the London zone it is known that 1749 were rejected for obvious physical defects, making a percentage of 67.2. Of those medically examined, the figure for the whole army is 35.7 per cent. rejected for medical reasons. The total would therefore appear to be approximately 50 per cent. of those applying.

MEDICINE AND THE LAW

Lightning and Workmen's Compensation

THE risks of injury due to the weather have raised interesting questions under the Workmen's Compensation Acts. If the workman is to recover compensation, his injury must have arisen not only in the course of his employment but also out of his employment. To be struck by lightning while at work is an injury arising in the course of the employment; it is not necessarily an injury arising out of the employment. The leading authorities include cases of bricklayers struck by lightning when on a high scaffolding, or sailors affected by heatstroke while painting the ironwork of a ship in the heat of a tropical sun. A recent decision in the Bath county court illustrates the legal issue. A workman died while employed on the Bath corporation's housing estate where a trench was being dug for the laying of iron water-pipes. On June 25th there was a violent thunderstorm and work proceeded at intervals. The dead man had a steel shovel with a wooden handle in his hand and was stooping to throw soil forward, with the shovel slightly raised. A second man was similarly employed within a few inches of him; a third was a few feet away. A wooden wheelbarrow was a few yards off; it had a steel rim to the wheel. Suddenly the deceased was thrown on to his back on the ground; there was a loud clap of thunder and a vivid flash; a neighbouring workman complained of shock. The county court judge was offered a large body of scientific evidence as to the effect of the wheelbarrow, the shovel, the pipe line, and the stacked pipes. He rejected this evidence as largely speculative and partly incredible. He came to the conclusion that the deceased, who had been badly burned, was directly struck by the lightning and that the electric discharge had not been attracted or conducted by the metal objects named. The parties agreed that the court had to decide whether the deceased, by reason of his occupation, was subject to a greater risk than usual. The judge found that there was nothing in the man's employment which added to the risk of his being struck. The deceased was in no greater peril than any other inhabitant in the city of Bath or immediate neighbourhood. The court was satisfied that the lightning which killed the workman had no kind of connexion, direct or indirect, with his employment. There was thus an award for the respondents, the Bath corporation, with costs. It is a pity that the experts' evidence was not more fully reported. What, one wonders, are the professional qualifications most acceptable to a court in expert witnesses who are to deal with the effects of lightning?

"Running Amok" with a Car

THE unsuccessful appeal in *R. v. Mortimer*, against a conviction for murder, disclosed strange facts and a neat point of criminal law. The accused stole a car at Aldershot and, next day, drove it along a lane where two sisters were riding their bicycles in single file ahead of him. Approaching them from behind, the car struck the rearmost cyclist and carried her and her bicycle along the road for about 30 yards on the bonnet. The woman then fell to the ground, dying later of her injuries, and the car drove on and disappeared.

In ordinary human affairs knowledge of a man's previous conduct and character is the first thing taken into account. If money has been stolen in

an office, a business man would at once suspect that a clerk who had been previously convicted of larceny had been the thief. The law carefully excludes such extraneous considerations. If a man is charged with theft, the prosecution is not entitled to offer evidence (except in certain carefully restricted contingencies) that the accused stole something else on some date earlier or later. One of the grounds for offering evidence of similar offences is the existence of a need to negative the idea of accident. In Mortimer's case the prosecution, having to prove that he intended either to kill or to cause grievous bodily harm, obtained permission at the trial to give evidence of three similar occurrences (two earlier, and one later, than the event which formed the subject of the present charge) in order to establish the intent and to negative the possibility that the event was an accident. The Court of Criminal Appeal decided on Jan. 13th that this parallel evidence was rightly admitted.

The defence in a case of this kind is naturally at a disadvantage if it takes two different lines. Mortimer's counsel relied on certain discrepancies in the evidence as to the number of the car and the clothing worn by the appellant. It would probably occur to the average reader to say that a man must be mad who acts as Mortimer was proved to have acted. Insanity was not pleaded, but it remains to be seen whether this may not be one of the cases where the accused, though deemed sane enough to be convicted of murder, is deemed not sane enough to be hanged.

Marriage of Girl under 16

One of the first cases under the Age of Marriage Act, 1929, was heard in the Probate, Divorce and Admiralty Division last week. A woman who was married on Sept. 27th, 1930, after giving her age in the marriage register as 17, now petitioned for a declaration that the marriage was null and void because she was in fact one month short of 16 years of age at the time. The court granted the declaration invalidating the marriage.

Food Preservative Prosecution

Three companies were fined last week at Tower Bridge Police-court, on proceedings at the instance of the Bermondsey borough council, for the sale of "Drywite Potato Preparation" in contravention of the Public Health (Preservatives, &c., in Food) Regulations. The proceedings raised the issue whether the language of the label would be likely to lead to an offence inasmuch as the preparation contained sulphur dioxide. It was stated that the label made reference to the washing but not to the cooking of fish; the preparation was described as a powerful deodorant. Experiments were said to have shown that, if fish were fried after treatment with the preparation, or were washed whole, no sulphur dioxide was found; but that when fillets of cod were washed in the preparation and analysed without cooking sulphur dioxide was revealed in minute quantities. The significance of the matter, it was suggested, lay not in the quantity of the preservative but in the fact that its use might lead to the consumption of unwholesome fish, since the preparation was capable of masking the evidence of putrefaction by removing smell or otherwise. For the defendant companies it was admitted that, in view of the statements made by the prosecution, the label might lead to the sale of uncooked fish containing prohibited preservative. A formal plea of guilty was entered and the companies undertook to discontinue the use

of the offending label. Fines were inflicted with costs. A further summons for failure to label the preparation as prescribed by the regulations was not separately dealt with; this part of the case related to the allegation that the declaration of the contents of the preparation was printed in type of smaller size than prescribed.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

X RAY EXAMINATION OF THE GASTRO- INTESTINAL TRACT

Dr. Robert McWhirter, who was recently appointed radiologist to Edinburgh Royal Infirmary, read a paper to the Medico-Chirurgical Society of Edinburgh last week on the examination of the gastrointestinal tract by radiology. He said that while in the early days of X raying the stomach only gross lesions were detected, modern apparatus and technique have enabled a very high degree of accuracy to be obtained in the diagnosis of diseases of the stomach and duodenum. The figures from the Mayo Clinic suggest that the degree of accuracy should be over 95 per cent.; this, however, is only possible with careful preparation of the patient and modern apparatus. While some radiologists like to have a full clinical history of the case before examination, Dr. McWhirter holds that no case notes should be supplied to the radiologist, in order that he may not be prejudiced by a clinical history. He proceeded to describe conditions of the œsophagus, stomach, and duodenum which can be diagnosed by X ray examination. In diseases of the stomach the preparation of the patient is simple but very important. No fluid or food should be given from 10 P.M. the night before examination. No purgatives are necessary. It should be possible, he said, to detect an ulcer crater the size of a pin-head and a carcinoma the size of a thumb-nail. Clinicians do not fully appreciate the fact that the diagnosis of diseases of the stomach and duodenum is made by screen examination alone and films are taken only for record purposes. The study of the mucous membrane pattern is of special importance in the detection of early diseases of the stomach. The presence of a residue in the barium in the stomach five hours after administration is often of no pathological significance. The diagnosis of pyloric stenosis can be made in five minutes on screen examination. In cases of duodenal ulcer the finding of the actual ulcer crater is always evidence of active ulceration; when only ulcer deformity is present the appearance may be due entirely to a healed ulcer. Dr. McWhirter went on to say that in his opinion the diagnosis of chronic appendicitis by radiology was impossible, and that a large amount of time and money was uselessly expended in attempting to demonstrate chronic diseases of the appendix. After considering the diagnosis of diseases of the large intestine and emphasising the importance of careful preparation for this examination, Dr. McWhirter referred to the examination of the gall-bladder by X rays. He said that intravenous injection of the dye used was no longer necessary, and emphasised the fact that the administration of the fatty meal was not to demonstrate the contractility but to make more obvious negative shadows within the gall-bladder. Dr. McWhirter's communication was illustrated by beautiful X ray photographs.

A PHYSIOLOGIST ON MEDICAL EDUCATION

Prof. E. W. H. Cruickshank, who has been appointed to the Chair of Physiology in Aberdeen University, delivered last week his inaugural lecture entitled *Some Views on Medical Education*. He said that the first purpose of medical education was to turn out men well equipped in the art and practice of medicine in all its phases; and the second was to discover and train men in creative work. He emphasised the need for general cultural education as an introduction to medical studies. The rigid lecture system had led to the evil of elaborate note-taking by the students and should as far as possible be replaced by the conference method, which, if carried out in small groups, was valuable in training the student in critical inquiry and in arriving at reasoned conclusions.

THE "OPEN-DOOR" POLICY

The abuse of the "open-door" policy has led the Board of the Royal Infirmary, Glasgow, to make use of its almoner's department for the purpose of giving patients who are able to pay the opportunity of contributing to the cost of their treatment. In so doing they are taking the step which the other large voluntary hospitals in Scotland will probably have to follow before long. The steady increase in the work done by the voluntary hospitals and the fact that all classes are going to make use of the treatment and advice that can be obtained in these hospitals will, in all probability, oblige them to make a charge to those who are able to pay.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

CONTROL OF PATENT MEDICINES

THE seventy-fourth Congress now reassembling after its vacation has before it no less than nine bills for the better regulation of the manufacture, advertisement, and sale of foods, drugs, therapeutic devices, and cosmetics. The most important of these is Senate Bill No. 5 introduced by Senator Copeland, of New York, who is a physician. This is described as—

"An Act to prevent the adulteration, misbranding and false advertising of food, drugs, devices and cosmetics in interstate, foreign and other commerce subject to the jurisdiction of the United States, for the purposes of safeguarding the public health, preventing deceit upon the purchasing public and for other purposes."

The bill has been critically analysed by the Bureau of Legal Medicine of the American Medical Association, who find that "there is grave danger of the enactment of an inadequate law—one that will not protect the consumer adequately, that will require expensive and prolonged litigation before it can be effectively enforced, and that may for another quarter century or more exclude from the statute books an effective law." The influence of the lobbies representing the cults is very obvious, and may well serve as a horrible example to English legislators. Thus "Drugs" as defined in the Copeland bill are so defined specifically for the purposes of this act and "not for the regulation of the legalised practice of the healing art." Why on earth not? one might reasonably ask. The only possible answer seems to be that certain State laws allow chiropractors to make adjustments but not to use drugs. Somebody seems to have been afraid that the Copeland bill by its definition of drugs might help to convict a chiropractor

of using drugs contrary to the statute of his particular State. The answer to the question *When is a drug not a drug?* will no doubt contribute to the cost of the "expensive litigation" referred to by the committee.

Again, "medical opinion" is defined as "the opinion within their respective fields of any branch of the medical profession the practice of which is licensed by law . . ." and the term "medical profession" means, despite appearances, "the legalised professions of the healing art." What becomes, then, of the bill's prohibition of false advertisements, seeing that the advertiser has adequate defence if only he can show that his statements are supported by "substantial and reliable medical opinion"? Presumably most juries will accept as such opinion, and will be instructed to accept it, the evidence of any half a dozen naturopaths. These and other weaknesses in the descriptive provisions of the bill are not offset by any rigidity in the provisions for enforcement. On the contrary the Secretary of Agriculture is expressly excused from prosecuting any "minor violations" if he thinks a "written notice or warning" is to be preferred. Considering that no guidance is offered as to what constitutes a "major" and what a "minor" violation, and that in practice the decision of whether or not to prosecute will inevitably devolve upon subordinates, the weakness of this provision is apparent.

The analysis by the American Medical Association will serve a useful purpose if it leads to correspondence between individual doctors or local societies and their representatives in Congress. It has not received and is unlikely to receive any notice in the lay press. Discussion of the provisions of the bill controlling advertisement, and of their present weakness, is not likely to be favoured by the powerful advertising interests.

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

UNEMPLOYED DOCTORS IN BARRACKS

At the request of the National Committee for Unemployed Graduates, the Ministry of Defence has provided shelter and board for 100 of these men, most of them doctors. They live in a vacant military barracks, in dormitories of 5-15 beds, with no other furniture than a long trestle table and benches and chairs. Clothes and linen are kept in bags, and shelves for books have been placed over some of the beds by the men themselves. Here they live in true good fellowship, without jealousy or discontent, and the only disputes are on scientific subjects. They themselves arrange the day's routine and discipline, which are scrupulously observed. In the morning after breakfast they scatter through the city in search of work. At noon they return to the barracks and after a simple meal they do domestic work. Needle and thread are taken out, and the hands trained to do operations now display great skill in repairing a solution of continuity in coat, shirt, or trousers. Some, lacking means to pay the shoemakers, show themselves able to sole and heel their boots. After further search for work they return early in the evening, having no money to spend in clubs, cafés, or music-halls. In this way the days and weeks are passed until some fortunate runs in, joyfully shouting that he has found a post as an assistant or parish doctor or in the health

insurance service. Hurriedly packing his bag he leaves his place to another of the unemployed, of whom the numbers are woefully great. There are no complaints, despite the contrast of barrack room and military food with their hopes when they qualified—hopes of appointments, assured status, marriage, and family life. Most of them are young and expect sooner or later to get work and realise their dreams; the barrack-room life is only a transitory stage and in the end the majority find satisfactory work.

THE ELDERLY PRIMIPARA

During the past 24 years Dr. Stephan Sztehlo, of the School of Midwifery here, has personally observed 5588 deliveries of primiparæ and has now reviewed them in order to determine the effect of age on labour. His findings agree with the general opinion of obstetricians that the influence of age is considerable. After thirty, a first labour is likely to be more troublesome, and one must be prepared for complications—especially in women who have become pregnant for the first time after many years of married life. The risk of long labours, inertia, post-maturity, hæmorrhage, and puerperal sepsis increases with the age of the patient, and from the point of view of pregnancy and labour, he thinks, the most favourable age for labour is 20–24 years.

A RHEUMATISM LIBRARY

In 1926 at Pistany, the thermal spa, the International League for the Campaign against Rheumatism was formed and it was then hoped that an international institute for research into muscular and articular rheumatism might be founded. A leading physician in the town has made plans for such an

institute, and they have been approved by the Ministry of Public Health. A library is the first part of the scheme to be realised and building will begin in February. Its objects are to attract students to Pistany, to offer them facilities for studying the literature, and thus to help research workers in their investigations.

MEAT CONSUMPTION IN HUNGARY

An average of 116 lb. of meat per head was consumed in Hungary in 1934, a figure which cannot be considered low compared with those of other European States. Financial stress caused only a slight decrease in meat consumption because of a simultaneous fall in the price of food, and particularly of meat. As might perhaps be expected, more is eaten in Budapest than in the countryside. Owing to the relative cheapness of beef, veal, and mutton, very little horse-flesh is now eaten, though it was once considered a delicacy.

FREE MILK IN THE SCHOOLS

In the poorer parts of the capital the city council have introduced the free milk system and to every child about a third of a pint is distributed each day. A recent report of Dr. Endre Tudós, lecturer in the university, shows that this distribution has considerably improved the condition of delicate or anæmic children, and the teachers have noticed faster progress, keener attention, and quieter behaviour. The minister of education is accordingly anxious to introduce the system in rural districts, where children badly need wholesome milk because, owing to the economic crisis, the small farmers with a few cows sacrifice their own and their children's health by selling their entire stock of milk to the city.

PUBLIC HEALTH

Maternal Deaths in L.C.C. Hospitals

THE strenuous efforts to improve the L.C.C. maternity services have caused an increased demand for admission and a lowered death-rate affecting almost every group. Dr. Letitia Fairfield,¹ reporting for the year 1934, records a total of 13,253 births, an increase of 1336 on the previous year, and a mortality-rate of 5.1 per thousand. The antenatal care reaches a very high standard. The Council demands one special examination for all booked patients, but the great majority attend more or less regularly at borough clinics. The divided responsibility for maternal care has always created difficulties in London, but there has been a marked improvement in coöperation during the past year. One of the chief difficulties of the Council is congestion, for Wassermann tests are now made on all women attending for the first time, and many more blood pressures are now taken than in earlier days. These precautions are justified by a comparison of the death-rate of those attending L.C.C. clinics with others.

Sepsis.—The mortality figures for the Council's hospitals cannot be compared with the country generally because these institutions are the chief resort for cases of abortion, and they also receive an undue proportion of women suffering from general diseases. They show, however, that sepsis is the commonest single cause of death in the Council's wards, as elsewhere. Deaths from true uterine

sepsis numbered 8 only (0.61 per thousand births), and of these only 5 were patients whose labour had been conducted entirely in the Council's hospital. If deaths after Cæsarean section and mastitis are included, the figure for 1934 is 1.18 per thousand births. There was nothing in the nature of an epidemic during the year, and in only one case of sepsis was there evidence of the source of infection, but the prevalence of mastitis in certain localities continues to give rise to anxiety. Certainly forceps do not appear to be the cause of sepsis in the Council's service. Dr. Fairfield thinks that one of the most important factors in the prevention of sepsis is the early detection and isolation of all cases of fever or other suspicious signs of early sepsis in a maternity ward. Improved accommodation is making this precaution possible in the Council's hospitals, with increasing success.

Apart from sepsis there were 4 "accidents of childbirth": 3 of the patients were admitted in extremis, one with a ruptured uterus and a shoulder presentation and two after "failed forceps." The fourth had had antenatal care from the Council and died from shock after craniotomy.

Accidental hæmorrhage and placenta prævia.—Of the 86 cases of accidental hæmorrhage admitted only 1 died, and she arrived moribund.

There were 98 cases of placenta prævia with 3 deaths, one from sepsis after several vaginal examinations made before admission. 13 Cæsarean sections were performed for placenta prævia without a death.

Anæsthesia.—There was 1 death attributable to anæsthesia: percaïne and a gas, oxygen, and ether

¹ L.C.C. Annual Report of the Council, 1934. Vol. iv., Part III. Public Health. Medical Supplement to the Report on the Hospital Services, p. 88.

mixture. She died five minutes after induction began without warning, before the operation was started, and the heart muscle showed degeneration. Of the 13,061 women delivered 4424 were given light intermittent anæsthesia, mainly by chloroform capsules, 850 had a general anæsthetic, 58 had a local anæsthetic, and 325 had analgesia by drugs in combination with some form of anæsthetic. Analgesia without an anæsthetic was supplied to 837 patients.

Cæsarean section was performed on 136 patients with 9 deaths. In most cases the indication was contracted pelvis and disproportion, but heart disease, placenta prævia, and toxæmia played their part. The operation was performed before labour in 74 cases with 5 deaths, early in labour in 30 cases with 2 deaths, and late in labour in 32 cases with 2 deaths. Four of the deaths were entirely due to the condition for which the operation was performed and the remainder were due to sepsis. Of the first group, one had very severe heart disease, one fulminating acute yellow atrophy of the liver, the third had chorea gravidarum, and the fourth a large pyelonephrosis.

The large strides made in preventing *eclampsia* and *toxæmia* have caused these diseases to be regarded as an indicator of the efficiency of antenatal care. Dr. Fairfield thinks that the argument can be pushed too far as, on the one hand, the patient may fail to recognise early symptoms however carefully she is instructed, or, on the other hand, the disease may be of the rare fulminating type which resists all treatment and gives no warning. During the year 41 cases of *eclampsia* were admitted; 12 had had antenatal care in the Council's clinics and 2 of these died; 29 had had care from other sources (or none) and 6 of these died. The time at which the fits developed illustrates the grave prognostic significance when the first fit is post-partum. In 11 cases the fits began before labour and in 22 cases during labour, and in each group there were 2 deaths. In 8 cases they began after labour, and half these women died. It is clear that periodic urine testing would not always provide an adequate warning: one woman who died never had any albuminuria at all, and in some cases the urine had been tested only a few days before the fits began and had shown nothing abnormal. The blood pressure is a valuable but not an infallible guide to the imminence of danger. Only one woman with *eclampsia* had a pressure below 130. Above this critical figure, however, the readings had little prognostic significance, as patients with a maximum of 140 died while those with pressures of over 200 recovered.

Another group of deaths recorded is that associated with pregnancy and confinement; this includes every woman who died between the twenty-eighth week of pregnancy and four weeks after delivery. Some of the deaths were purely coincident, while in others childbearing played an obvious part. Dr. Fairfield points out that a quite extraneous cause such as an influenza epidemic might easily affect the maternal mortality-rate and create fallacious alarm, while over-careful certification might over-weight the figures. Instances have been known where a woman died from phthisis or heart disease weeks after childbirth and was classified as a "maternal" death.

Dr. Fairfield concludes by remarking that the close inquiries into every maternal death in the Council's hospitals show that no obvious or easily eliminated cause for a high mortality-rate exists.

The only possibility of a further reduction lies in a steady improvement of staffing, accommodation, and organisation, together with loyal coöperation on the part of the patient.

Speech Training and the C.A.M.W.

An increasing number of local education authorities have made provision for the treatment of stammering and other speech defects; at the present time 40 authorities provide classes which children attend for a period of about 50 minutes on two occasions per week, while 10 authorities provide classes where full-time attendance is arranged, but, as is pointed out in the C.M.O.'s recent report, many authorities still do not appreciate that inability to speak distinctly is an even greater reflection on the educational system than is failure to acquire the art of writing. The Central Association for Mental Welfare has, during recent years, arranged for an expert in speech-training to visit certain areas in order to investigate the problem of children with speech defects. Before her visit, ascertainment of the number of such children has been carried out by head teachers and the names of such children sent in to the education office. The speech expert, Miss Marion Fleming, has then examined the children in coöperation with the school medical officer, after which suitable children have been taught in classes arranged on the lines of those which are held in London. In addition to the actual training of children with stammering and other speech defects, Miss Fleming has lectured to teachers and others interested in the problem, given demonstration lessons before teachers from the contributory schools, and she has also paid a number of home visits.

The school medical officer for Coventry has included in his annual report a statement by Miss Fleming of the incidence and histories of stammerers in the Coventry schools. In association with the assistant school medical officer information relating to 158 stammering children was obtained, and the following conclusions were arrived at:—

1. Of the stammerers investigated, 62 per cent. were either the eldest or the eldest but one in the family, while 21.5 per cent. were the youngest members of their respective families; in the larger families containing stammerers, therefore, the incidence of stammering appears to be least among "middle" children.

2. In about one-quarter of the cases, either the father or the mother was also a stammerer.

3. It appears that there is no notable connexion between "left-handedness" and stammering.

4. As expected, findings indicating stammering as a functional nervous disorder were numerous; among them 75 per cent. of the cases were noted as being nervous and "highly-strung"; 22 per cent. of the cases were nail-biters; 62 per cent. of the cases were said to speak more easily at home than at school.

5. In most cases, the cause of the stammer was not evident. The findings under the headings of causation are hardly compatible in some directions with findings under other headings. For instance, "imitation of others" is given as the cause in but 5.7 per cent. of cases, whereas stammering in one or other of the parents, which is likely to elicit imitative response in the child, is recorded as occurring in as many as 22.7 per cent. of the cases investigated.

Miss Fleming only remained for a period of from six weeks to two months in the area. This time, as she points out, is too short for definite results to be obtained in the treatment of stammerers. The great advantage of the arrangement, however, is that local interest was aroused, and in more than one of the areas which she visited it is proposed to appoint a whole-time teacher for children with stammering and speech defects.

CORRESPONDENCE

CONTROL OF MEASLES

To the Editor of THE LANCET

SIR,—Dr. J. D. Rolleston's historical résumé of the subject of the serum prophylaxis of measles in your last issue (p. 168) was of great interest. Stating that Dr. Brincker was incorrect in his belief that the first attempt to modify measles in this way was first made only 40 years ago, he refers to Frances Home's pioneer work on this subject in 1765. He then states that Dr. Hugh Thompson, of Glasgow, employed this method successfully in two cases (1890). I was able to discuss this with the late Sir Leslie Mackenzie just before his death, and he then informed me that Thompson had subsequently published a considerably larger series of cases with similar results. I am unfortunately unable to find any reference to this series, and it would be of considerable interest to hear if any of your readers are able to give information with regard to this.

I believe that I am correct in saying with regard to the modern method of prophylaxis and attenuation of measles by means of convalescent serum that I was the first to introduce it to this country some years prior¹ to the epidemic of 1929-30 in which it was used with such success.

I am, Sir, yours faithfully,

Harley-street, W., Jan. 20th. W. S. C. COPEMAN.

SYNTROPAN IN SEA-SICKNESS

To the Editor of THE LANCET

SIR,—May I draw your attention to the effectiveness of the new synthetic vagus depressor, Syntropan, in sea-sickness. As ship's surgeon travelling between Australia and London, and vice versa, during two very stormy periods, I have had some rather intensive experience. The first trip, homeward bound, in November-December, was made in a severe Mediterranean storm, and a severe Atlantic storm in which the wind reached gale force, as recorded in the ship's log, for the best part of ten days. Conditions aboard ship were at their worst, and most passengers were sick—some exceedingly sick. On the outward journey in July-August, the monsoon was at its height, a man being lost overboard from a sister ship passing us. There were seven days of bad weather and much sickness.

A total of 140 cases of sea-sickness was treated, 100 with Syntropan preparation No. 2190/14, and 40 with Vasano, and with the usual mixture of hyoscyamine and bromide. Syntropan and vasano were equally effective in removing almost instantly the feelings of nausea that precede the sickness. The hyoscyamus mixture was not so effective in ambulatory cases. When vasano was replaced by syntropan, the passengers thereafter preferred the syntropan preparation because it did not give rise to the intensely dry mouth which is also produced by hyoscyamus. Two tablets, morning and afternoon, served to cure the worst cases. The usual difficulty in dealing with patients unable to keep the tablets down was overcome by using suppositories of the same material. Passengers who were occasionally overcome, when given two tablets of the syntropan preparation, were almost immediately restored, so that the efficiency of the preparation became a subject

of comment; one tablet sufficed in mild cases. Moreover, I cured a fellow officer, and myself, just as rapidly, by taking two tablets when the stage of real discomfort had been reached.

Why syntropan should act so effectively on the gastric vagus and have so little action on the salivary parasympathetic supply, is not at all clear; it may be a matter of differential rates of penetration of the drug into the neighbourhood of the various parasympathetic endings that is the explanation. The result, however, is remarkable, and anyone knowing the discomfort of the dry mouth produced by hyoscyamine will agree that a remedy so effective as that reported is indeed worthy of mention.

The composition of the preparation is as follows:—

Syntropan..	0.01 g.
Sedormid	0.1 g. per tablet.

syntropan being phosphate of the 3-diethylamino-2,2-dimethyl-propylester of tropic acid.

I am, Sir, yours faithfully,

C. STANTON HICKS,
Professor of Pharmacology and Human
Physiology, University of Adelaide.
Nov. 6th, 1935.

DR. ALBERT GRAY'S TECHNIQUE

To the Editor of THE LANCET

SIR,—May I in amplification of the account of Dr. Albert Gray's work contained in your obituary notice last week add something about the method of making transparencies of the membranous labyrinth which he devised and employed with such success in his work "The Labyrinth of Animals." This process yields at one stage perfect casts of the bony labyrinth, but the finished product is much more than a cast and contains all the structures of the membranous labyrinth, perfectly cleared and preserved. I am, Sir, yours faithfully,

C. S. HALLPIKE.

Ferens Institute of Otolaryngology, Middlesex
Hospital Annexe, Jan. 20th.

COLLAPSE THERAPY IN PLEURISY AND PNEUMONIA

To the Editor of THE LANCET

SIR,—I read with much interest the observations of Dr. C. Shaw in your issue of Dec. 7th, 1935 (p. 1280), on artificial pneumothorax for the relief of acute pleural pain. I made observations on 12 cases so treated (Calcutta Med. Jour., August, 1934) which did well and I remarked:

"It was quite reasonable to think that it should be so, because the partial collapse of the lung at once stopped friction between the two inflamed layers of the pleura, gave rest to the diseased area, relieved local congestion and pain and hastened repair and convalescence. Further, by maintaining this state of partial collapse by giving more fillings afterwards, healing was perfect, and the chance of relapse or formation of adhesion or effusion was very much minimised. The author is in touch with some of these cases for over two years and they are keeping perfectly fit."

I read with equal interest Dr. W. E. Robertson's paper in the same issue of THE LANCET (p. 1282), for I had treated similarly 20 cases of pneumonia with excellent results—only 3 deaths—my main difficulty being to find a sufficient number of suitable cases.

Since the influenza pandemic of 1918-19, the infective organisms of acute catarrh of the respiratory

¹ Jour. of Hyg., 1925, xxiv., 427; Proc. Roy. Soc. Med. (Sec. Epidem.), 1927, xx., 1609.

tract are usually of mixed character, true lobar pneumonia, in Calcutta at least, being comparatively rare. The usual picture is one of acute bronchial catarrh, in some cases with patches of consolidation forming from day to day, which by fusion give rise to pseudo-lobar consolidation. In these cases as well as in true lobar cases A.P. treatment often gave a very favourable result. With Dr. Robertson I have found that (1) A.P. does confer almost instant relief upon those suffering from coincident pleuritis; (2) it ameliorates cough and expectoration; (3) it frequently lowers the temperature, sometimes to a surprising extent. Dr. Robertson thinks that it does not cut short the attack of pneumonia, but in my cases I found that A.P. treatment nearly always brought down the pulse and the respiratory rate, lessened toxæmia, and caused considerable improvement in general condition, thus shortening the course of the disease and reducing its mortality.

Specific treatment with Felton's serum is very expensive; typing is difficult, and once consolidation has been established serum is not so effective. In all late cases A.P. treatment is more suitable. Dr. Robertson has pointed out that it is innocent of any collateral ill-effects, to which I fully agree. Since 1932 in my wards in the Campbell Medical School and Medical College Hospitals it has been routine treatment to perform partial collapse in all cases of uncomplicated acute primary pleurisy and circumscribed lobar-like consolidation. The quantity of air introduced varies from 100 to 400 c.cm., depending mainly on the amount of pleural space available. In some cases one operation was sufficient but in others it had to be repeated, and in bilateral cases partial collapse was maintained on both sides.

I am, Sir, yours faithfully,

Calcutta, Jan. 2nd.

A. R. MAJUMDER.

ABDOMINAL VARICOSITIES

To the Editor of THE LANCET

SIR,—In your issue of Jan. 11th Mr. A. L. d'Abreu describes two cases of varicose veins of the legs which showed by the presence of abdominal varicosities that some obstruction was present in the deep veins of the trunk, and states that he regards the existence of the latter as prohibiting the treatment of the leg veins. His view, however, is not securely founded either on theory or fact. If the saphenous veins show a positive Trendelenburg test they can be safely treated whether the patient has obstruction of the vena cava or not. Some years ago I obliterated the varicose veins in the legs of a similar case with satisfactory results and showed the man before a society, not because I regarded the treatment as unusual, but because the deep obstruction in the abdomen appeared to be congenital. Further, it is held by some, including Dickson Wright (Brit. Med. Jour., 1931, ii., 561), that even when the obstruction is in the deep veins of the leg itself the superficial varicosities are merely an added embarrassment to the circulation, and I have treated several such cases without regret. It would, of course, be generally regarded as bad treatment to deal with the abdominal veins, but V. Meisen (Varicose Veins and Hæmorrhoids, London, 1932, p. 50) has done so in a case with deep abdominal thrombosis, and apparently without ill-effect, and with cure of the coincident eczema. It is a curious fact that these abdominal varicosities sometimes appear without any apparent cause for obstruction of the inferior vena cava or the iliac veins.—I am, Sir, yours faithfully,

Birmingham, Jan. 16th.

J. W. RIDDOCH.

Short Service Commissions: Lts. J. G. M. A. Brunet and R. O. A. Leroux to be Cpts.

ROYAL AIR FORCE

Medical Branch.—Wing Comdrs. P. T. Rutherford, O.B.E., to Headquarters, Fighting Area, Uxbridge, for duty as Principal Medical Officer, vice Group Captain K. Biggs, M.C., and E. C. K. H. Foreman to No. 10 Flying Training School, Ternhill, for duty as Medical Officer.
Squadron Leader C. A. Lindup to No. 8 Flying Training School, Montrose, for duty as Medical Officer.

Dental Branch.—Flying Officer Alexander Maben, L.D.S., is promoted to the rank of Flight Lt.

Flight Lts. Hugh Bannerman, F. W. P. Dixon, and C. R. Palfreyman have been selected for permanent commissions in the medical branch, subject to physical fitness; they entered as flying officers in 1930–32.

INDIAN MEDICAL SERVICE

Lts. (on prob.) to be Cpts. (on prob.): I. J. Franklen-Evans, J. Duffy, and K. Cunningham.

Lt.-Col. B. Higham, C.I.E., retires.

Indian Medical Department.—Maj. (Sen. Asst. Surg.) T. J. Gibson retires.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
JAN. 11TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2397; diphtheria, 1264; enteric fever, 21; acute pneumonia (primary or influenzal), 1571; puerperal fever, 58; puerperal pyrexia, 117; cerebro-spinal fever, 23; acute poliomyelitis, 7; acute poli-encephalitis, 1; encephalitis lethargica, 7; dysentery, 21; ophthalmia neonatorum, 91. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 17th was 3850, which included: Scarlet fever, 1098; diphtheria, 1150; measles, 433; whooping-cough, 599; puerperal fever, 17 mothers (plus 11 babies); encephalitis lethargica, 280; poliomyelitis, 4. At St. Margaret's Hospital there were 18 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 43 (4) from measles, 5 (0) from scarlet fever, 28 (5) from whooping-cough, 36 (7) from diphtheria, 44 (12) from diarrhoea and enteritis under two years, and 110 (18) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza is the same as last week, the total deaths for the last six weeks (working backwards) being 110, 110, 80, 67, 62, 45. They are scattered over 56 great towns, Birmingham reporting 8, Oldham 5, Bradford and Newcastle-upon-Tyne each 4, Luton, Leeds, Sheffield, and Coventry each 3, no other great town more than 2. Liverpool and Manchester each had 9 deaths from measles, Bristol and Nottingham each 4. Liverpool also reported 8 deaths from whooping-cough. Deaths from diphtheria were reported from 18 great towns: Liverpool 4, Hull 3, Darlington, Sheffield, Warrington, and West Hartlepool each 2.

The number of stillbirths notified during the week was 246 (corresponding to a rate of 37 per 1000 total births), including 33 in London.

OBITUARY

ANDREW FRANCIS DIXON, M.B., B.Ch. Dub.

THE death occurred on Jan. 15th of Andrew Francis Dixon, professor of human anatomy and embryology in the University of Dublin. Born in 1868, he came of a well-known Dublin family. One of his brothers occupies the chair of botany in Dublin University and another until lately was professor of engineering in the City and Guilds College of Engineering, London, while his uncle, R. V. Dixon, was a fellow of Trinity College.

Francis Dixon entered Dublin University in 1885 and had a brilliant academical career, gaining a senior moderatorship and gold medal in natural science and securing many other distinctions, as well as obtaining in 1893 the medical degrees M.B., B.Ch., B.A.O. During the course of his medical studies he first came in contact with the late Prof. D. J. Cunningham who so greatly influenced his career. His early interests were in zoology and his first publications were concerned with the marine invertebrates, in which he was intensely interested all his life. But in 1893 his attention was turned more definitely towards human anatomy and he went to Leipzig to study under the late Prof. His. A year later he was appointed chief demonstrator in anatomy in Trinity College, Dublin, under Cunningham. In 1897 he was appointed professor of anatomy in University College, Cardiff, but in 1903 he returned to his old college to succeed Cunningham as professor of anatomy and chirurgery in the medical faculty, and from that date his whole-hearted service and loyalty were devoted to Trinity College. In 1916 he was appointed the representative of the college on the General Medical Council; in 1922 he was appointed to the newly founded chair of human anatomy and embryology, and in 1924 he became dean of the Faculty of Physic. And perhaps his greatest work was his devotion to the interests of the students and the ardour with which he worked for them, especially in their early post-graduate years. He was keenly interested in all their activities and took a very large part in organising the Trinity College Association with the object of keeping them in touch with each other and with their college. He was also actively interested in the old O.T.C. and in the Dublin University Biological Association, of which society he was president in 1904-05.

Outside the University Prof. Dixon had a very wide circle of friends and interests. He was a life-long member of the Anatomical Society of Great Britain and Ireland, and was elected president of that society in 1934. From 1917 to 1925 he was a member of the council of the Royal Dublin Society and in the latter year was appointed a governor of the society. On six separate occasions he was elected a member of the council of the Royal Irish

Academy, and in 1919 and again in 1926-27 he was a vice-president. For thirty years he was a member of the council of the Royal Zoological Society of Ireland, and from 1927 to 1931 was their president. He was a fellow of the Royal Academy of Medicine in Ireland and in 1906-08 was president of the section of anatomy and physiology. In 1934 he was appointed warden of Alexandra College. His many personal friendships and his wide sympathies made him a very valuable link between the university and outside bodies.

In his younger days Dixon published many interesting contributions to anatomical science. Our knowledge of the development of the fifth cranial nerve, of the course of the taste fibres, of the structures in the female pelvis, and of many interesting features in the skeleton has been considerably extended by his researches. But in later years pressure of administrative duties and heavy responsibilities in directing the medical school necessarily curtailed his time for such work. But those who knew him realised that he possessed an amazing fund of original observations and accurate knowledge on many interesting points, and regretted that lack of time and his own modesty prevented him from committing them to print.

He will be remembered always as a very loyal and warm-hearted friend. His memory for faces was extraordinary, and Trinity men revisiting the college after a lapse of many years were always sure of a warm personal welcome from the dean. For the college itself he entertained such a loyal devotion that no task was either too large or too menial for him to undertake if he felt that its interests were concerned.

We have received from our Dublin correspondent the following estimate of Dixon's great services, not only to his University but to the scientific world:—

"For nearly half his life—thirty-two years—Francis Dixon was head of the department of anatomy in the School of Physic; for nineteen years he represented the University of Dublin on the General Council of Medical Education and Registration, and for eight years on the Irish Medical Registration Council; he represented the professors of the university on the board—the governing body—of Trinity College; he was for many years past dean of the School of Physic. It is clear that the character of the school during the last thirty years must have been largely influenced by him. It is difficult for any but his colleagues to realise how sound and constructive was that influence, and how kindly, wisely, and unselfishly it was exercised. With an essentially conservative outlook and with a firm confidence in the mode of education which was traditional in Dublin, he never ceased his determination to keep that education in touch with modern requirements. He insisted on his students learning their anatomy

A. Francis Dixon

soundly, but he never forgot that his first duty was to fit them for medical practice. At the same time any senior student or young medical man who desired to study anatomy more deeply or to investigate any particular problem of anatomy with a clinical bearing received every encouragement and facility. When he was appointed in 1903 to the chair he succeeded two great anatomists—Alexander Macalister and Daniel John Cunningham; in his hands the reputation of the school of anatomy, both as a teaching institution and as a centre of research, was not only maintained but increased. He contributed frequently to the various scientific journals, and he always had something solid to contribute. His publications were marked by clarity, precision, and modesty. His teaching of his anatomy class had the same characters, and he held the attention and roused the interest of his students without apparent effort. He contributed the section on urogenital anatomy to Cunningham's 'Text-book of Anatomy,' and gave much assistance to the editor in the production of the first edition. He also wrote a 'Manual of Human Osteology' which has become a favourite text-book in many schools. His chief interests in original work lay in the fields of embryology and comparative anatomy.

"His responsibility as dean of the school kept him in touch with the work of all his colleagues. His influence on them and their work was more that of an elder brother than of an official of the university. He never intruded and never interfered, but his advice and help were at the disposal of all of them, and it is only since his retirement that they realise how much they had come to rely on him. They knew that his advice would be wise, and would be given without any slightest touch of self-interest or self-seeking. A shy man and a modest, he never liked pressing his opinions on others, but nevertheless he held strongly to his own convictions, and when a difference of opinion occurred he stated his views clearly and tersely, and then left it to others to make their decision according to their conscience as he had made his.

"His relations with his pupils were of the happiest. He did not tolerate slackness and he insisted on a high standard of work, but it was only in the rarest cases that he adopted disciplinary measures. Many a respected and respectable practitioner, inclined in his youth to idleness or folly, can look back to the help and guidance of Dixon as one of the important influences in his career.

"Dixon's friends will remember with pride his honourable career, his achievements, his services to his University, and to medical education. Their pride will, however, be lost in their affection for the man, the wise counsellor, the trusty friend whose friendship never stood out so strong as in time of trouble or anxiety."

JOHN BRIGHT BERRY, M.D. Edin.

Dr. John Berry, who died on Jan. 11th at the age of 79, was the doyen of the medical profession at Keighley. He graduated as M.B., C.M. Edin. in 1880, proceeding at a short interval to the M.D. degree. He practised for a time at Bradford, but some 40 years ago went to Keighley and pursued his vocation there until he retired in 1920. During a great part of his life in Keighley Dr. Berry held an honorary consulting position to the Victoria Hospital and he was closely connected with the Bradford Medico-Chirurgical Society of which he

was past-president. He always showed himself a skilful and progressive surgeon and was the first man to excise a diseased joint at the Keighley Hospital, while it is a matter of interest that he should have attended Lister's last course of lectures in Edinburgh. A correspondent writes: "Dr. Berry was the real doctor, available to anyone at any time, fee or no fee, and many of the older generation in Keighley will remember him with feelings of real affection."

STEWART RANKEN DOUGLAS, F.R.C.P. Lond., F.R.S.

DEPUTY DIRECTOR, NATIONAL INSTITUTE FOR MEDICAL
RESEARCH, HAMPSTEAD

WE regret to announce the death of Captain S. R. Douglas, deputy director of the National Institute for Medical Research, Hampstead, and director of the department of experimental pathology, who died at his residence in Buckingham-gate, London, on Monday, Jan. 20th, at the age of 64.

Stewart Douglas was born at Coulsdon Grange, Caterham, in 1871, the son of the late Mr. J. A. Douglas. He was educated at Haileybury, and proceeded for his medical training to St. Bartholomew's Hospital. He qualified with the English double diploma in 1896 and entered the Indian Medical Service as a surgeon-lieutenant. He did good work quite early in his career under the Plague Commission, and served with the China Expedition in 1900-01, being promoted captain and receiving a medal for his services. After the expedition he was invalided home much broken in health, but he determined to return to work and pursue a career of medical research that had already deeply attracted him. At this period he came into a close association with Sir Almroth Wright at

CAPT. S. R. DOUGLAS

[Photograph by Elliott & Fry]

St. Mary's Hospital, and from 1907 for seven years was assistant director of the inoculation department at this hospital and a member of the medical staff of the institution as lecturer on bacteriology in the medical school. His status as a teaching pathologist was thus established. In 1903 he communicated to the Proceedings of the Royal Society in collaboration with Sir Almroth a paper on the experimental investigation of the rôle of the blood fluids in connexion with phagocytosis. In the next year followed further observations on the rôle of the blood fluids and a communication on the protective substances elaborated in the blood in response to inoculation with a tubercle vaccine. These papers were also read before the Royal Society, while he published in THE LANCET (this in association with Major F. W. Hardy) some valuable pathological observations on bilharzia diseases, and in 1907, also in THE LANCET, a report on infective endocarditis

cured by the inoculation of a vaccine prepared from organisms found in the patient's blood.

Thus at the outbreak of war Captain Douglas's scientific reputation was well established. On August 1st, 1914, he had been appointed to the bacteriological staff of the Medical Research Council but instead of taking up this work he took a commission in the R.A.M.C. and was for a time engaged in research work in France. But here the duties proved beyond his physical strength and he was soon invalided home, but only to continue his work enthusiastically. He was engaged in the laboratories of St. Mary's Hospital in organising the production of vaccines for the use of the troops and in making special researches on, among other things, infection in wounds and dysentery; for these valuable labours he was decorated and appointed also Chevalier de l'Ordre Couronne, Belgium.

In 1922 Douglas was elected F.R.S. and appointed director of the pathological department at the National Institute for Medical Research, later becoming deputy director of the institute.

In 1920 he married Frances, née Dayrell, widow of Dr. J. B. Nias, but leaves no children.

To the many who came into personal contact with him, as to ourselves, Douglas's genial manner, unvarying kindness, and aptitude for friendship made an appeal that will not be forgotten. In the tributes which follow these characteristics of the man are displayed.

Sir Henry Dale, Sec. R.S., writes:—

"The sudden news of the death of my staunch friend and dearly loved colleague S. R. Douglas reached me by cable while I was in Holland at the week-end. I had known and liked him at casual meetings for some years, before we became in 1914, just before the war, fellow members of the then newly appointed nucleus staff of the future National Institute for Medical Research. War activities separated us, and it was not till the institute begun its work at Hampstead, in 1920, that our intimate association began. Douglas was then acting director of the institute's largest department, dealing with bacteriology and experimental pathology, and was made full director of it a year or two later; Leonard Hill, John Brownlee, and I directing the other three departments, as originally conceived. Brownlee's death, and Hill's retirement by seniority some years ago, had left Douglas and myself the only remaining members here of the original staff. The organisation of the institute and with it the official form of Douglas's relation to myself have undergone some changes in the years that intervened; but never has there been any hint of change in the confidence and loyal friendship, in the quiet and unselfish help and coöperation, which he has given to me, as to every member of our growing staff of colleagues, through the sixteen years of our close collaboration. We had all come to know even much more of Douglas's scientific worth than his modest self-effacement showed outside our circle, and we all know that we have lost a colleague whose genius for friendship and unselfish instinct for adjustment have been of priceless value to the happy coöperation of our community."

Sir Patrick Laidlaw, F.R.S., writes:—

"It has been my great privilege to know Captain Douglas for the last fifteen years. This may seem a fair period but I feel it was not nearly long enough. Throughout most of this time I worked under him or with him at the National Institute for Medical

Research, and to me, as to all other workers in the department of experimental pathology, which he largely helped to build, he was unfailingly kind in giving advice, encouragement, or criticism. For example, both Dunkin and I are greatly indebted to him for assistance in the distemper investigation. He was in close touch with all the virus studies under progress in his department, and indeed initiated some and frequently guided a whole research, though his name did not appear on the final publication. He brought to the study of virus problems a mind ripe with bacteriological knowledge and experience gained in India, China, and at St. Mary's Hospital with Sir Almroth Wright, to the great benefit of less mature research workers.

"Douglas was always keenly interested in 'acid-fast' bacilli and diseases produced by them. He developed special synthetic media for the cultivation of the tubercle bacillus and produced a stock of tuberculin prepared from such a medium for use in a projected international inquiry. He was greatly interested in biochemical studies in connexion with tubercle bacilli, and assisted the late G. A. C. Gough's chemical studies by growing the necessary bacilli in large quantities, suggesting and assisting in new lines of work. The work on John's disease of cattle carried out by Dunkin at the institute farm at Mill Hill was helped forward by Douglas in the early stages. The same story might be repeated; Douglas in the background initiating new studies, encouraging his juniors, allowing them full freedom to develop their own ideas, and kindly to a fault even when criticism was necessary. Apart from pathology, which was his life work, Douglas was a keen field naturalist particularly interested in bird life and migration—e.g., he published two papers on the migration of woodcock. He was an ardent fisherman and enjoyed a good day's shooting. At the institute there is a gap which will never be filled, and my colleagues and I feel we have lost a very good friend."

Dr. Leonard Colebrook writes:—

"My recollections of 'Dougie'—most lovable of men—range over the years 1906 to 1921. I see him in the early days of the 'opsonic' era at the midnight tea parties at St. Mary's along with 'The Old Man' as we always called Sir Almroth Wright (he was then only 45), delighting us all with good stories, and banter, and shrewd comment upon whatever the work of the day had thrown up. From the tea parties we went back to a further bout of counting of phagocytic films, and Douglas perhaps to wrestle with some problems of technique till 2 or 3 in the morning. In technical skill he was our recognised master, for, without any special training, he had acquired an uncanny sense of how a job should be done. Hence it was that he contributed not a little to the 'technique of the teat and the capillary glass tube,' although the fundamental ideas and the stimulus to work them out came nearly always from Sir Almroth.

"At the outbreak of the European war, Douglas was quick to see the urgent need for bacteriological media that would yield better crops than those in current use if we were to produce the huge quantities of typhoid vaccine which were required for the Allied armies. This matter had been simmering in his head for some time and in the early autumn of 1914 he was able to publish in THE LANCET a description of the tryptic digest medium which usually bears his name and has been so widely employed ever since. This must rank as one of his most useful achievements. It was something of a calamity

when he went to Boulogne with Wright a few months later and started to create a laboratory in a damp cellar for the study of wound infections. Very severe sciatica soon sent him home and crippled him for years, but in spite of constant pain and want of sleep he carried on all through the war with cheerful curses, but never a complaint, and did valuable work at St. Mary's directing researches on Gallipoli dysentery and on wound infections. In this work I think he was at his best—and very happy—for he had a real flair for clinical observation and wise treatment—seeing always the man as well as the disease.

"I count it great good fortune to have been so closely associated with one so disinterested and so essentially efficient in all he undertook. For the rest, it may be truly said of him that he 'warmed both hands before the fire of life.'"

JEFFREY ALEXANDER AMHERST ORLEBAR, M.B., B.Chir. Camb.

Dr. J. A. A. Orlebar, whose death occurred on Jan. 1st at Hove, was honorary physician in charge of out-patients at Brighton and Preston Dispensary. He was 56 at the time of his death. Dr. Orlebar was the son of the Rev. J. E. Orlebar, rector of Glencarse, and was educated at St. John's School, Leatherhead, and Magdalene College, Cambridge, whence he proceeded for his medical training to St. Thomas's Hospital. He obtained the double English diploma in 1905 and graduated as M.B., B.Chir. Camb. in the same year. After holding an appointment at the Tewkesbury Hospital and acting as medical officer of health to the Brixworth rural district council, he was appointed house physician at the Royal Sussex County Hospital, Brighton, filling also the posts of assistant pathologist and bacteriologist. During the war he held a commission as temporary captain, R.A.M.C., and served in Suvla Bay, when his experience in the treatment of malaria led to his appointment as medical officer in charge of a tropical diseases clinic in connexion with the Ministry of Pensions. Apart from his purely professional work he took a practical interest in the St. John Ambulance Brigade and in the local activities of the British Medical Association.

MURDO BUCHANAN, M.B., Ch.B. Glasg.

Dr. Murdo Buchanan, who died on Jan. 9th at Darlington, was born on the island of Lewis and was educated at the Nicolson Institute, Stornoway, and the University of Glasgow. At Glasgow he graduated as M.B., Ch.B. in 1907, and on qualification became for a time surgeon to the St. Helen's Collieries. Later he practised at Bishop Auckland, Durham, but since 1916 was a partner in a practice in Darlington. He enjoyed a high local reputation as physician and surgeon and was appointed deputy coroner some three years ago. He was also keenly interested in ambulance work. Although only 53 years of age his death was not unexpected, as he had been in failing health for some time.

EDWARD ARGENT SAUNDERS, M.R.C.S. Eng.

THE death is announced at the age of 50, after a short illness, of Dr. Edward Argent Saunders, medical officer of health for Pembroke. The son of a well-known Welsh physician, he was educated at Epsom College and entered the medical school of the Middlesex Hospital, where he held the Freer Lucas scholarship. He took the English double diploma in 1912 and served as house surgeon at the Middlesex

Hospital when he returned to practice in Pembroke where in the course of a busy and successful career he obtained a large number of public appointments, being at the time of his death medical officer of health and school medical officer for the borough of Pembroke, civil medical officer in charge of the R.A.F. station at Pembroke Dock, in charge of the county fever hospital, and medical officer of the Post Office. He was actively interested in the work of the St. John Ambulance Association and of the local infant welfare clinic. Dr. Saunders was a keen sportsman, good with gun and rod, and his unexpected death occurred on return from a shooting expedition.

FRANCIS EDWARD FERNIE, M.R.C.S. Eng.

Dr. Francis Fernie, who died on Jan. 9th at Stone, at the age of 68, was a well-known and respected figure in the Stafford district. He was the eldest son of the late Dr. Edward Fernie, of Stone, was educated at Wellingborough school, and received his medical training at St. Bartholomew's Hospital. On qualifying with the English double diploma in 1893 he was for a time house surgeon at the Stockport Infirmary, returning to go into partnership with his father. As a young man Dr. Fernie was a prominent footballer, while to the end of his life he was a remarkably fine horseman.

TREATMENT AND DISPOSAL OF LONDON SEWAGE

AT a sessional meeting of the Royal Sanitary Institute, held on Jan. 14th, Mr. J. H. Coste, chief chemist to the London County Council, described some improvements which had been made in treatment of the ever-increasing flow of sewage from the London main drainage system. The method of sedimentation, with or without the aid of chemical precipitants, which has been in use since the days of Sir Joseph Bazalgette and Mr. W. J. Dibdin, has been remarkably successful, but recently experience has shown that the calls which are being made upon the London main drainage system and on the capacity of the River Thames as the final place of disposal have reached a point when further steps should be taken. In his paper Mr. Coste described the large activated sludge plant designed on lines suggested by Lieut.-Colonel W. Butler and Mr. E. H. Tabor, M.I.C.E., as the result of long-continued research by the L.C.C.'s officers. This plant, in which aeration for treatment is almost entirely effected at the interface between the mixture of activated sludge and the sedimented effluent which is to undergo further purification, is so arranged that the liquid flows through a two-tiered long channel, divided into 66 compartments, alternately being exposed to air and plunging into the lower compartment. By details of construction there is imparted to it a swirling motion, so that the air-liquid interface is continually renewed and absorption of oxygen from the air goes on rapidly. After travelling 6400 feet (over a mile) the issuing liquid goes to sedimenting tanks of two types: pyramidal, which yield better separation of solid from liquid and shallow Dorr tanks with scrapers which yield a denser sludge; thence the liquid part flows into the common effluent channel and the sludge to re-aeration tanks. These are fitted with diffuser tiles which have been found better adapted for aeration of sludge than the surface absorption used for the treatment itself. The plant

was constructed in the hope that it would suffice for treatment of from 5 to 10 million gallons a day. Since July, 1932, with very little intermission, 10 million gallons a day have been treated. At first it was sought to obtain a stable effluent; experiment has shown that the greatest effect of purification is obtained by producing a less purified effluent in greater amount.

A second direction of improvement has been explored in the form of sludge digestion, by means of which a large volume of gas of high calorific power is obtained, available for the production of heat and power, and a sludge of reduced organic content. The principal source of gas seems to be the mixture of fatty acids, present in part as soap in the sludge, and Mr. Coste and his colleagues have shown by micro-combustion and the difficulty in liquefying the gas that methane is the only hydrocarbon present in appreciable amount—a fact which has hitherto been assumed but not demonstrated. A large sludge digestion plant is to be constructed at the northern outfall, but this will supplement and not supplant disposal at sea; also five more units of activated sludge plant of the same capacity and on similar lines to that now in use are being constructed.

During the recent dry summers it has been found that some more thorough process than sedimentation,

supplemented by the use of ferrous sulphate as a fixative for sulphuretted hydrogen, was needed for the hot dry months of the year. Experiments made in the winter of 1934 with a variety of oxidising agents showed that ferric salts were the most suitable for such emergency treatment. It was found, however, that the quantities required—hundreds of tons a week—could not be obtained commercially. Experiments were, therefore, initiated on the chlorination of ferrous sulphate, which was obtainable. These were successful on the laboratory scale and at once plant of sufficient size was constructed at the southern outfall, followed by an improved plant at the northern. The work was not completed sufficiently early in the year 1935 for an unsatisfactory condition of the river to be avoided entirely, but the character of the effluent was undoubtedly improved and it is hoped that with the ability to start treatment at any moment, the condition of the Thames may remain satisfactory during the summer months. When the five activated sludge units under construction are completed still better conditions should be secured. Mr. Coste expressed his personal opinion that further improvements should be in the direction of better sedimentation and coagulation of sewage which had been brought to the outfalls in a non-septic condition.

MEDICAL NEWS

University of Cambridge

A course of lectures on human genetics will be delivered during the Lent term by Dr. L. S. Penrose, research medical officer of the Royal Eastern Counties Institution, Colchester. The lectures will be given on Fridays, at 5 P.M., and the first will be on Friday, Jan. 24th.

University of London

Prof. B. A. McSwiney has been appointed to the university chair of physiology at St. Thomas's Hospital medical school.

Dr. McSwiney, who was born in Chicago in 1894, received his medical education in Dublin. In 1915 he was awarded the Reuben Harvey scholarship by the Royal College of Physicians of Ireland for his work as student demonstrator in the school of physiology, but his work was interrupted by service as a naval surgeon-probationer. Returning to complete his medical course, he graduated as M.B. in 1917, worked for a time as assistant scientific adviser to the Ministry of Food, and in 1918 saw further war service with the R.A.M.C. After a brief period as assistant professor of physiology at Trinity College, Dublin, he went to Leeds in 1919 as university lecturer in experimental physiology, being appointed to the same post at Manchester a year later. He returned to Leeds in 1926 to fill the chair of physiology, and during his tenure of it has acted as examiner for the universities of Oxford, Cambridge, and Manchester, and for the National University of Ireland. His work has been largely concerned with pulse-wave velocity and the physiology of plain muscle, and he became a D.Sc. of Dublin in 1928.

Two lectures on perimetry will be given by Dr. H. M. Traquair, lecturer on diseases of the eye in the University of Edinburgh, at 5.30 P.M. on Feb. 10th and 11th, at University College Hospital medical school. On March 3rd, 6th, and 10th, at the same hour, Dr. Kuczynski, formerly director of the statistical office, Berlin-Schönberg, will lecture at University College on recent population trends. Lord Dawson will take the chair at his first lecture.

Society of Apothecaries

A livery dinner of this society will be held at Apothecaries' Hall, Water-lane, London, E.C., on Tuesday, Feb. 25th, at 7.30 P.M., when the Lord Mayor and sheriffs intend to be present.

Papworth Village Settlement

Dr. Walter Pagel will give a demonstration on the experimental production of early pulmonary tuberculosis in the Sims Woodhead memorial laboratory at Papworth Village Settlement on Saturday, Feb. 15th, at 3 P.M. All who are interested and wish to attend should communicate with Dr. Pagel at Papworth Hall, Cambridge.

Society of Public Analysts

A joint meeting of this society with the food group of the Society of Chemical Industry will be held on Wednesday, Feb. 5th, at the Chemical Society's rooms, Burlington House, Piccadilly, London, W. The afternoon session begins at 5 P.M. and the evening session at 8.15 P.M., and both will be devoted to a discussion on tea and coffee, with special reference to their tannins and alkaloid. The first paper of the evening session will be read by Dr. G. Roche Lynch, who will speak on the pharmacology of caffeine and of tea and coffee.

Dr. Barnardo's Homes

Last year 1396 children were admitted to Dr. Barnardo's Homes, among whom was the 118,000th child to be welcomed under the charter "no destitute child ever refused admission." The number at present in the Homes is about 8300, of whom 1455 are under 5 years of age.

Prince of Wales's Hospital, Plymouth

Lord Onslow recently opened at this hospital a new administrative and paying patients' block which has cost £40,000. Twenty-six paying patients can be accommodated and there are now enough rooms to enable all the nurses to sleep in hospital.

Ella Sachs Plotz Foundation

The trustees of this foundation are anxious to make known the resources of their fund for the advancement of scientific investigation. The foundation seldom or never offers stipends to investigators; nor does it provide apparatus and materials which are ordinarily part of laboratory equipment. Its special purpose is to give grants for the purchase of apparatus and supplies required for special investigations and for the payment of unusual expenses, including technical assistance. The research should bear closely on medicine or surgery, and the maximum size of grants will usually be less than \$500. In the twelve years of its existence the foundation has made 252 grants and investigators have been aided in 26 countries. Applications for assistance should arrive before May 1st, including statements about the nature of the investigation, the amount of money wanted, and the way in which it will be spent. The secretary of the executive is Dr. Joseph C. Aub, Collis P. Huntington Memorial Hospital, 695, Huntington Avenue, Boston, Massachusetts, U.S.A.

King Edward's Hospital Fund for London

In aid of this Fund five special tours have been arranged, beginning with a visit to the Board of Admiralty and the Foreign Office, conducted by Mr. D. B. Smith and Mr. C. Howard Smith, on Feb. 8th. The other places to be visited will be the Houses of Parliament (Feb. 19th), the India Office (March 7th), Westminster Abbey (April 22nd), and the Zoological Gardens (May 8th). Tickets may be had from the secretary of the Fund, 10, Old Jewry, London, E.C.2.

German Congress for Actinotherapy

The third International Congress for Actinotherapy will be held in Wiesbaden from Sept. 1st to 7th under the presidency of Prof. W. Friedrich, director of the Institut für Strahlenforschung of the University of Berlin. Problems relating to the biology of light, to biophysics, and to the therapy of light will be discussed. Further information may be had from the secretary-general of the Congress, Dr. H. Schreiber, Robert Koch-Platz 1, Berlin, N.W.7.

Fifty Years of Public Service

On Jan. 17th Dr. Henry Lloyd received a presentation to commemorate his 50 years as poor-law medical officer for St. Asaph and district, an appointment he has held since the age of 25. Dr. Lloyd's brother, the late Dr. David Lloyd, was for many years medical officer for Denbigh, and he has two daughters in the medical profession, Dr. Muriel Radford and Dr. Katherine Quinby. The presentation was made by the Lord-Lieutenant of Flintshire.

Hospital Extensions at Southend

Southend borough council have decided to spend £304,000 on improving and extending the municipal hospital. There has been much opposition to the scheme on the ground of expense and the measure was passed only by a majority of 2.

Boscombe Hospital

The enlargement of the nurses' hostel of this hospital will probably be finished in April and two new operating theatres, a new ward with 24 beds, and three observation wards are also in course of construction. It is hoped to build a new maternity block later in order to free medical and surgical wards.

Paying Patients at Swindon

A scheme known as the Swindon and North Wilts Hospital Private Ward League is being inaugurated this month. An annual subscription of £1 ls. entitles a single man and £2 2s. a married man with a family to assistance in the cost of maintenance in the private wards of Swindon Victoria Hospital or in nursing-homes. X ray examinations and other expenses are included in the scheme. Full scale benefits are only payable after a year's membership.

Society for Relief of Widows and Orphans of Medical Men

At a meeting of the court of directors held on Jan. 1st the president, Mr. V. Warren Low, being in the chair, the deaths of five members were reported and five new members were elected. Four widows of deceased members applied for relief; a grant of £60 a year was voted to each, one widow over 65 receiving an additional £15 a year; two orphans had grants of £50 a year each. A sum of £2082 10s. was voted to cover the half-yearly grants to the 55 widows and 10 orphans in receipt of relief. The distribution was reported of £625 as a Christmas gift to the widows and orphans, each widow over 75 receiving £15, under 75 £10, and each orphan £10. A legacy of £45 had been received from the executors of the late Dr. W. Culver James, a vice-president of the society. Particulars of membership, which is open to any registered medical man who at the time of his election is residing within a 20-mile radius of Charing Cross, may be obtained from the secretary at 11, Chandos-street, London, W.1.

Scottish Board of Control

Dr. Laura Margaret Dorothea Mill has been appointed a deputy commissioner of the General Board of Control for Scotland.

Fellowship of Medicine and Post-Graduate Medical Association

Advanced courses will be held in proctology at St. Mark's Hospital (Feb. 3rd to 8th); in chest diseases at the Brompton Hospital (Feb. 10th to 15th); in gynaecology at the Chelsea Hospital (Feb. 10th to 22nd); and in anatomy and physiology for the F.R.C.S. (primary) in the Infants Hospital (Mondays, Wednesdays, and Fridays at 8 p.m., Feb. 24th to April 24th); and a M.R.C.P. clinical class will meet at the National Temperance Hospital, Hampstead-road, on Tuesdays and Thursdays from Feb. 25th to March 12th at 8 p.m. An all-day course in neurology will be given at the West End Hospital for Nervous Diseases (Feb. 3rd to 8th), and week-end courses include one in physical medicine at the St. John Clinic and Institute of Physical Medicine (Feb. 8th and 9th), one in children's diseases at the Princess Elizabeth of York Hospital (Feb. 22nd and 23rd), and one in chest diseases at the Brompton Hospital (March 7th and 8th). Courses are open only to members and associates. Full particulars and detailed syllabuses can be obtained from the secretary of the fellowship, 1, Wimpole-street, London, W.1.

British Red Cross Society and Order of St. John Hospital Library

The organising secretary of this movement (48, Queen's-gardens, Lancaster Gate, London, W.2) announces the delivery on four Wednesday evenings at 5.30 p.m. of the following addresses at the Foyle Art Gallery, Charing Cross-road, London, W.C.2. On Jan. 29th Miss Ann Bridge will speak on the novel and the conventions; on Feb. 12th Miss Dorothy Sayers will speak on the importance of being vulgar; on Feb. 26th Mr. Humbert Wolfe will give readings from his own works; and on March 11th Mr. Maxwell Fry, A.R.I.B.A., and Mr. A. R. Duncan, A.R.I.B.A., will start a debate, the former instructing the audience how to live and the latter taking up the attitude that we should live as we like. Tickets for the course are 2s. 6d. for a single lecture and 8s. 6d. for four lectures. The hospital library run under the aegis of Red Cross and the Order of St. John merits all the support that medical men can either personally give it or direct towards it. The organisation already sends gifts of books to over 2000 hospitals, and the amount of pleasure and profit which patients derive therefrom must be extremely large.

INDEX TO "THE LANCET," VOL. II., 1935

THE Index and Title-page to Vol. II., 1935, which was completed with the issue of Dec. 28th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Appointments

GOODWIN, AUBREY, M.D. Lond., F.R.C.S. Eng., has been appointed Obstetric Surgeon to the Westminster Hospital.
HEWLETT, R. F. L., M.B., Pathologist at the Group Laboratory, Lambeth Hospital, L.C.C.
MACKAY, J. S. B., M.B. Aberd., D.P.H., Assistant Tuberculosis Officer for Manchester.
MCNAB, G. H., M.B. Edin., F.R.C.S. Eng., Surgical Registrar at the Hospital for Epilepsy and Paralysis, Maida Vale.
MILLER, ARTHUR, F.R.C.S. Edin., Consulting Oto-laryngologist to the Wimbledon Fever Hospital.
MILNER, J. G., M.B. Camb., F.R.C.S. Eng., Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.
RUNDLE, FRANCIS, M.B. Sydney, F.R.C.S. Eng., Surgical Registrar at the Westminster Hospital.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Jan. 27th.

Odontology. 8 P.M. Mr. Cyril Howkins: The Blood-supply of the Lower Jaw. Mr. R. Bradlaw: Innervation of the Teeth.

TUESDAY.

Medicine. 5 P.M. Dr. Otto Leyton: The Morbid Conditions which Cause Progressive Hyperglycemic Glycosuria and the Circumstances which Modify its Course. Dr. J. Graham Willmore, Dr. H. P. Hims-worth, and Dr. T. C. Hunt will also speak.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.
MONDAY, Jan. 27th.—8.30 P.M., Mr. V. Zachary Cope: The Treatment of Acute Appendicitis.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Thorn-haugh-street, W.C.

FRIDAY, Jan. 31st.—Mr. A. Felix, D.Sc., and Dr. C. J. McSweeney: The Serum Treatment of Typhoid Fever. (Fever group.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, Jan. 27th.—5 P.M., Mr. E. P. Stibbe: The Anatomy and Surgery of the Subtentorial Angle.

WEDNESDAY.—5 P.M., Mr. R. T. Payne: Pyogenic Infections of the Parotid.

FRIDAY.—5 P.M., Mr. George A. Mason: Extirpation of the Lung. (Hunterian lectures.)

UNIVERSITY OF LONDON.

FRIDAY, Jan. 31st.—11 A.M. (London School of Hygiene, Keppel-street, W.C.), Mr. H. E. Magee, D.Sc.: Nutrition.

ROYAL INSTITUTION, 21, Albemarle-street, W.

FRIDAY, Jan. 31st.—9 P.M., Prof. E. Mellanby, F.R.S.: Advances in the Treatment of Disease.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, N.W.

WEDNESDAY, Jan. 29th.—4 P.M., Dr. A. J. Scott Pinchin: Points in the Diagnosis and Treatment of Pulmonary Tuberculosis.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.

TUESDAY, Jan. 28th.—5 P.M., Dr. J. L. Franklin: Bullous Eruptions.

WEDNESDAY.—5 P.M., Dr. I. Muende: Histopathology.

THURSDAY.—5 P.M., Dr. W. K. Sibley: Electrotherapeutics.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

WEDNESDAY, Jan. 29th.—2 P.M., Dr. Wilfrid Sheldon: Medical Aspects of Empyema, Pulmonary Abscess, and Pyopneumothorax. 3 P.M., Dr. W. W. Payne: Blood Chemistry in Normal Respiration.

Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Jan. 27th.—3.30 P.M., Dr. Hinds Howell: Neuro-syphilis (I).

TUESDAY.—3.30 P.M., Dr. Critchley: Cerebral Vascular Disease (I).

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Dr. Carmichael: Subacute Combined Degeneration.

FRIDAY.—3.30 P.M., Mr. Elmquist: Demonstration of Re-educational Methods.

Out-patient clinic daily at 2 P.M.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Jan. 27th, to SATURDAY, Feb. 1st.—ST. JOHN'S HOSPITAL, 5, Lisle-street, W.C. Afternoon course in dermatology. (Open to non-members.)—ST. PETER'S HOSPITAL, Henrietta-street, W.C. All-day course in urology.—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. Tues., 8.30 P.M., Mr. Hamilton Bailey: Neck. Thurs., 8.30 P.M., Mr. A. Dickson Wright: Skull and Brain.—Courses are open only to members of the fellowship.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.

WEDNESDAY, Jan. 29th.—4 P.M. (St. James's Hospital, Ouseley-road, S.W.), Mr. George Perkins: Fractures in General Practice.

LEEDS GENERAL INFIRMARY.

TUESDAY, Jan. 28th.—3.30 P.M., Mr. Jeaftresson: Ante-partum Hemorrhage.

LEEDS PUBLIC DISPENSARY AND HOSPITAL.

WEDNESDAY, Jan. 29th.—4 P.M., Mr. A. D. Sharp: Ear, Nose, and Throat—Selected Cases.

UNIVERSITY OF DURHAM.

SUNDAY, Feb. 2nd.—10.30 A.M. (Newcastle General Hospital), Mr. J. Collingwood Stewart: Selected Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, Jan. 29th.—4.15 P.M. (Eye Infirmary), Dr. J. Barbour Stewart: Squint and its Treatment.

Vacancies

For further information refer to the advertisement columns

Abyssinia (Gondar).—Two M.O.'s. Each £600.

Ayr Royal Burgh.—M.O.H. £800.

Barry Surgical Hospital.—Res. Surg. O. £350.

Bath, Royal United Hospital.—H.S. At rate of £150.

Beckenham, Bethlem Royal Hospital, Monks Orchard.—Jun. Asst. Phys. £350.

Birmingham City Maternity and Child Welfare Dept.—Temp. M.O. £10 per week.

Birmingham, Romsley Hill Sanatorium.—Res. Asst. M.O. £240.

Blackburn, Brockhall Institution for Mental Defectives, Langho.—Jun. Asst. M.O. £500.

Blackburn and East Lancashire Royal Infirmary.—Res. Surg. O. £250.

Bradford Royal Infirmary.—H.S. At rate of £135.

Bridport and Lyme Regis Boroughs, &c.—M.O.H. £800.

Buxton Clinic for Rheumatism and Allied Diseases.—H.P. At rate of £200.

Canterbury, Kent and Canterbury Hospital.—H.P. At rate of £125.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Third Res. H.S. At rate of £75.

Chester Royal Infirmary.—H.P. and H.S. Each £150.

Colchester, Royal Eastern Counties' Institution for the Mentally Defective.—Asst. M.O. £350.

Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose, and Throat Depts. £175.

Downpatrick, Down Mental Hospital.—Jun. Asst. M.O. £300.

Dulwich Hospital, S.E.—H.P. At rate of £120.

East Ham Memorial Hospital, Shrewsbury-road, E.—H.P. At rate of £150.

Edmonton, North Middlesex County Hospital.—Jun. Res. Asst. M.O. At rate of £250.

General Lying-in Hospital, York-road, Lambeth, S.E.—Jun. Res. M.O. and Anesthetist. At rate of £100.

Gloucestershire Royal Infirmary, &c.—H.S. At rate of £150.

Hertford, Ware Park Sanatorium.—Asst. M.O. £300.

Hove General Hospital.—Hon. Phys. to Brighton Branch.

Ipswich Sanatorium, Foxhall-road.—Asst. M.O. £350.

Lambeth Hospital, Brook-street, S.E.—Asst. M.O. £350.

Leeds General Infirmary.—Hon. Asst. Phys.

Leicester City General Hospital.—Two Res. M.O.'s. Each £300.

Liverpool, Mill-road Infirmary.—Res. Asst. M.O. £200.

Liverpool, Sanatorium, Dclamere Forest, Frodsham.—Second Asst. Med. Supt. £200.

Liverpool, Smithdown-road Hospital.—Res. Asst. M.O. £200.

Liverpool, Walton Hospital.—Res. Asst. M.O. £200.

London County Council.—M.O. for Henniker House, Parsons Green. £100.

Maidstone, Kent County Ophthalmic and Aural Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £200.

Manchester Ear Hospital, Grosvenor-square, All Saints'.—H.S. At rate of £150.

Middlesex County Council.—Asst. M.O. £600.

Mile End Hospital, Bank-road, E.—Asst. M.O. £350.

Newcastle-upon-Tyne, Hospital for Sick Children.—Res. Surg. O. £250.

Northampton County Mental Hospital, Berrywood.—Second Asst. M.O. £450.

Paddington Hospital, Harrow-road, W.—Asst. M.O. £350.

Plymouth City.—Deputy M.O.H. £750.

Preston, W'rightington Hospital, Appley Bridge.—Jun. Asst. M.O. £200.

Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—H.P. At rate of £100.

Queen's Hospital for Children, Hackney-road, E.—Res. M.O. At rate of £200. Also H.S. and Cas. O. Each at rate of £100.

Romford, Oldchurch Hospital.—Asst. Res. Radiologist and Jun. Res. M.O. Each £250. Also General Consulting Phys. £300.

Royal National Orthopaedic Hospital, 234, Great Portland-street, W.—Asst. Res. Surg. for Country Branch. £250.

Royal Naval Medical Service.—Eight vacancies.

St. Allege's Hospital, Vandrugh Hill, S.E.—Asst. M.O. £350.

St. Andrew's, Devon-road, E.—H.P. At rate of £120.

St. Thomas's Hospital, S.E.—Reg. and Tutor to Obstet. Dept. £250. Also Reg. to Ophth. Dept. £150.

Salisbury General Infirmary.—H.S. At rate of £125.

Shrewsbury, Royal Salop Infirmary.—Res. H.S. At rate of £160.

Shrewsbury, Salop Mental Hospital.—Asst. M.O. £350.

Southend-on-Sea General Hospital.—Cas. O. At rate of £100.

Stirling District Mental Hospital, Larbert.—Jun. Asst. M.O. £300.

Stockport Infirmary.—H.S. £150.

Stoke-on-Trent, Stanfield Sanatorium.—Res. M.O. £250.

West London Hospital, Hammersmith-road, W.—Half-time Pathologist. At rate of £300.

West Riding of Yorkshire County Council.—School Medical Inspector. £500.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Surg. to Inoculation Dept.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—H.P. At rate of £100.

Worcestershire County Council.—County Analyst and Bacteriologist. £800.

The Chief Inspector of Factories announces vacancies for

Certifying Factory Surgeons at Coggeshall, Essex;

Frodingham, Lincs; and Auchtermuchty, Fife.

NOTES, COMMENTS, AND ABSTRACTS

A STUDY OF
MILK CONSUMPTION IN AN OUTER
LONDON SUBURBBY E. H. R. SMITHARD, M.D. Lond., D.P.H.
MEDICAL OFFICER OF HEALTH, SOUTHALL

THE district council of Southall-Norwood has for many years supplied wet (as well as dried) milk, free or at half cost according to an economic circumstances scale, to expectant and nursing mothers and to children under three years of age attending the infant welfare centres. Children over three and under five years of age are also granted milk if there are definite medical reasons for its use. The procedure has been to write an order on a milkman chosen by the family, and as free choice has always been allowed, this has meant that the usual family milkman has supplied the milk and has been paid by the council.

The health department has been increasingly careful about the maintenance of cleanliness in the dairies of all retailers and there is no doubt that a great improvement has been made in the cleanliness of the milk retailed. From time to time, however, consistently unsatisfactory bacteriological results have been obtained from the milk of certain dairymen, and so it was decided to institute an investigation into the safety or otherwise of all the milk consumed in the district. The primary object of this investigation was in order to see if sufficient of the milk consumed was "safe" to warrant confining the council's payments to retailers who sold safe milk; the results may be of more general interest in showing the amount of milk consumed in an average London suburb.

Southall is a district, on the fringe of greater London, which has grown rapidly in recent years. There are about 100 factories of varying size in the area, but a proportion of the working population appears to be to an increasing extent of the dormitory type. The population, as calculated to the middle of 1934 by the Registrar-General, was nearly 47,000. It is almost certain that it is now (at the time of the investigation) just about 50,000. Of this figure, 3000 are resident in a mental hospital in the district, and this hospital, which has its own milk-supply, has been excluded from the figures given below, thus leaving a net population for the purpose of this investigation of 47,000. The area forms a convenient unit of its own with natural boundaries except in two small districts, and the figures given for the total consumption of milk may be taken as reliable.

The figures of milk consumed have been obtained from the retailers, in confidence as far as their names are concerned, and where the retailers have served both this and a neighbouring district an assessment has been made of the amount consumed in this district. I have no reason to doubt the reasonable accuracy of the totals submitted.

GRADING

Table I. gives the grouped results of the investigation. Two columns have been included which show the difference between the largest and the smallest amounts of classified milks sold by individual retailers.

Of the pasteurised milk, excluding that done by

the flash method, only 18 per cent. is pasteurised in the district, the rest being imported from firms outside. The milk so imported comes from eight different firms. Dalrymple-Champneys¹ has given

TABLE I

Milk retailed during first week in October, 1935. Number of retailers, 21; total number of retail shops, 41

Description.	Number of retailers.	Amount sold in pints by retailers.		Total sold—Pints and percentage.
		Larg-est.	Small-est.	
1. Legally pasteurised (including Grade A Past.)	9	28,555	780	100,936 (62·15)
2. Otherwise pasteurised—				
(a) Ordinary	9	7,680	1,200	34,244 (21·08)
(b) Flash ..	1	—	—	13,500 (8·31)
3. Certified ..	2	124	3	127 (0·08)
4. Grade A (T.T.)	6	237	12	553 (0·34)
5. Grade A ..	8	200	16	772 (0·48)
6. Sterilised ..	10	2,912	12	4,506 (2·78)
7. Homogenised ..	7	1,254	8	2,946 (1·81)
8. Sun ray ..	1	—	—	8
9. Raw	3	2,800	10	4,810 (2·99)
		Total	..	162,402

in detail the requirements for the proper supervision of milk pasteurising plants, but it has been felt for some time that a check on the end-result, more simple and reliable than bacteriological counts, which may be completely unreliable (Howell²) or which may appear satisfactory even when the milk is not properly pasteurised, is required. Kay and Graham,³ of the National Institute of Research in Dairying at the University of Reading, have recently evolved a simple test which they claim will show—

(a) whether milk has been heated to 1½° F. below the minimum temperature for pasteurisation, or

(b) whether it has been heated (at 145° F.) for twenty minutes or less, instead of the required thirty minutes, or

(c) whether raw milk (down to 0·25 per cent.) has been mixed with properly pasteurised milk.

The principle is the hydrolysis of a phosphoric ester when incubated with milk containing phosphatase, and the colorimetric determination of the end-products. The enzyme phosphatase is a constant constituent of raw milk but is destroyed on heating to a certain temperature. This test, the phosphatase test, should prove very useful in checking the minimum requirements of a pasteurising plant. It does not however apparently indicate whether the maximum temperature (of 150° F.) has been exceeded, or by how much, or for how long, but this is immaterial when the only question is that of the safety of the milk examined.

Most of the pasteurised milk (legally, flash and otherwise) sold in this district was examined in this way by the National Institute of Research in Dairying, and of the sixteen samples submitted three failed to pass the test. Two of these were samples of flash pasteurised milk; the other was a sample of milk stated to be pasteurised but not sold as such. This related to a dairy selling 1600 pints of the above

total, and further inquiry revealed a reasonable certainty that raw milk had been added to it.

Excluding the milk to which these unsatisfactory results relate and also Nos. 7, 8, and 9 in Table I., a total of 139,738 pints is left (86 per cent. of the whole) which can be regarded as safe milk.

BACTERIOLOGICAL RESULTS

A check was also made at the time, and has been repeated subsequently, by obtaining bacterial counts. These are well known to be frequently inconsistent, but in this district, using the same outside laboratory, quite consistent results are usually obtained. In the period under review the results appeared particularly consistent and they are shown in Table II.

TABLE II.—*Bacterial Counts*

Description.	Number of samples.	Bacterial count.		Samples in which <i>B. coli</i> found in	
		Highest.	Lowest.	0·1 c.cm.	0·01 c.cm.
1. Legally pasteurised	4	85,000	8,300	1	0
2. Otherwise pasteurised—					
(a) Ordinary ..	5	800,000*	51,000	4	0
(b) Flash ..	4	31,200	9,000	2	1
3. Certified ..	1	3,400		0	0
4. Grade A (T.T.) ..	4	91,600	10,000	1	0
5. Grade A ..	4	4,000	100	0	0
6. Sterilised ..	2	200	100	0	0
7. Homogenised ..	1	6,000		0	0
8. Sun-ray ..	1	1,000		0	0
9. Raw	5	Millions (3)	92,000	5	4

*All the other samples were under 100,000.

These results are rather striking in that the only samples containing *B. coli* in 0·01 c.cm. are of raw milk (all except one of the samples submitted) and of flash pasteurised milk. The samples, too, in which *B. coli* were found in 0·1 c.cm. were mostly from dairies where the conditions generally obtaining were not such as to make these results unexpected. On the other hand, the sample of Grade A (T.T.) containing 91,000 organisms and *B. coli* in 0·1 c.cm. was a little surprising, and there must have been a slip up in the technique (although the result is well within legal standards). Some doubt, too, may be cast on a sample of Grade A milk containing only 100 organisms, but although it is not suggested that these analyses are of sufficient number to do more than indicate the gross differences between different milks, they are carried out at the same laboratory, and, as stated above, with similar conditions very consistent results are obtained.

AMOUNT OF MILK CONSUMED

The Astor Committee⁴ found that in January, 1918, the average consumption per head per day in London was just under a third of a pint. In August, 1925, the then Minister of Agriculture stated that the milk consumption per head of the population was 20 gallons a year. This is equivalent to about 0·44 pint per day, but probably did not take into account the amount used in manufacture of other articles for home consumption and for export. Variable figures for different towns and areas in Scotland

are quoted by Paton and Findlay.⁵ These ranged from 0·27 pint per man-value per day in a part of Glasgow in 1921, to 1·31 pints per man-value per day in an agricultural population in Ayrshire in 1924. These figures are roughly equivalent to 0·2 and 1·0 pints per head of population per day. Other investigations have been made from time to time into the amount of milk consumed per head of the population. In 1932 the Ministry of Health Advisory Committee on Nutrition⁶ reported that the consumption per head was still less than half a pint a day. More recently Leighton and McKinlay⁷ find that in large Scottish burghs the consumption was 0·417 pint, and in Scotland as a whole it was 0·479 pint. The Milk Marketing Board⁸ this autumn (1935) state that the consumption is 0·38 pint per head per day, but that this is only approximate.

The figures in this present communication show that in Southall, taken as a whole, the average consumption per head per day is just under half a pint. There are, however, three modifying factors which should be considered:

1. The amount of milk used in food factories (artificial cream, bakeries, margarine works, &c.) and likely to be consumed in the district. Inquiry shows that approximately 200 pints should be deducted from the total on this account.

2. The amount of milk consumed by persons while working outside the district. This will cover lunch and possibly tea, and to a large extent it will be offset by the fact that another large number of people (in the factories, &c.) have lunch and tea in the district although living outside.

3. The amount of dried milk used. During the week in question 107 lb. of dried milk (equivalent to 616 pints) were sold from the infant welfare centres. I have also ascertained that almost exactly the same amount of dried milk (109 lb., equivalent to 627 pints) was sold at shops (chemists, &c.) in the district during the week in question.

These extras make practically no difference to the daily consumption, which is 0·497 or just under half a pint per head. It will be seen, therefore, that the consumption per head per day appears a little larger than in the Scottish burghs and definitely larger than for the country as a whole.

COMMENT

Much opposition has been experienced from time to time by local authorities in obtaining powers for compulsory pasteurisation of milk. This has usually been based on the alleged rights of small traders, cost of plant, &c. The figures quoted in this communication are probably typical for any part of the metropolitan police area (covering 8,000,000 people) and indicate that there are in fact very few retailers who do not sell either pasteurised or otherwise safe milk, and that the total quantity of pasteurised or otherwise safe milk sold is a very high proportion of all milk sold. The time probably is at hand when standing committees on private bills, or even the Ministry, may be persuaded more easily to accept the principle of compulsory pasteurisation for all milk which is not otherwise bacteriologically controlled.

SUMMARY

1. The milk-supply of an outer London suburb with 50,000 population is analysed.
2. The milk consumption per head is just under 0·5 pint daily.
3. The amount of efficiently pasteurised milk sold is 82 per cent. of the whole.
4. The amount of "safe" milk sold is at least 86 per cent. of the whole.

5. The phosphatase test has been found useful in deciding whether a pasteurising plant is turning out safe milk.

THE REFORM OF MEDICAL STUDIES IN ITALY

THE proposals of the commission nominated by the Italian Ministry of Education have been published in the Italian medical press. The report recognises the grave gaps apparent in the education of the present general practitioner, and finds as causes (1) the licence which permits students to attend their later studies before passing the earlier examinations; (2) the number of natural sciences taught in the first two years; (3) the number of examinations in special subjects in the last year; and (4) the lack of practical clinical training. The commission recommends that the medical curriculum of six years should be divided into three periods of two years. During the first anatomy and physiology are to be studied for two years, and chemistry, physics, and biology for a year apiece. The student must pass in all five subjects before being admitted to the study of the subjects of the second period. In their second period are two-year courses in (1) general pathology, (2) special medical pathology, (3) special surgical pathology, and (4) pathological anatomy and histology with a course of one year in pharmacology and materia medica. Again the student must pass in all five subjects before entering on the last period of his training. In the last two years there are 11 compulsory and three special subjects. The compulsory subjects are: (1) clinical medicine, and (2) clinical surgery, in each case a two-year course, to be followed by six months of practical training. Diseases of children, obstetrics and gynaecology, hygiene, and forensic medicine are each to be studied during one year. Nervous and mental diseases, skin and venereal diseases, eyes, throat, nose and ear, and dental disease are each to be taught in a course of 25 lecture-demonstrations. In addition, the student must select, and be examined in, at least three of the following extra subjects: (1) biological chemistry, (2) general histology and embryology, (3) microbiology, (4) parasitology, (5) experimental psychology, (6) tuberculosis, (7) tropical diseases, (8) orthopaedics, (9) radiology, (10) infectious diseases, (11) industrial medicine, (12) history of medicine, (13) urology, and (14) surgical anatomy and operative surgery. The instruction given in each of these subjects will also be in the form of 25 lecture-demonstrations.

It will be seen that the Italian student will now have to pass 24 examinations in order to obtain his degree in medicine and surgery. This is of interest to us as Italy is at present the only continental country whose medical degrees are registrable in this country.

ARTIFICIAL PNEUMOTHORAX CENTRES IN HUNGARY

ON behalf of the Hungarian sanatorium and dispensary doctors Dr. Sander Puder¹ has made a survey of pneumothorax treatment in the kingdom and of the centres where refills can be given. Questionnaires sent to hospitals, sanatoriums, dispensaries, and

practitioners—274 in all, of whom 60 per cent. replied—showed that at the end of 1933 there were 2183 cases undergoing collapse therapy. It seems that there are each year 20,000 deaths from tuberculosis which, at three open cases to a death, would make 60,000 cases of open tuberculosis in the country. At a modest estimate 30 per cent. of these, or 18,000 cases, might be suitable for that form of treatment. How desirable it is that they should get it is evident from Dr. Puder's statement that 60 per cent. of cases so treated lose their bacilli. Every medical institution in the country should, he thinks, have an artificial pneumothorax centre, and where there are none new dispensaries should be provided. There should be specialists at the centres where the first puncture should always be made, but practitioners could, after some special training, do the refills. The patients should if necessary have their travelling expenses paid, the cost of the scheme being met in equal shares out of the taxes, rates, and national insurance, with the help of a special tuberculosis stamp.

THE CLIMATE OF PENMAENMAWR

DR. DENNISON PICKERING, medical superintendent of Pandyffryn Hall, Penmaenmawr, writes: "During the spells of foggy and wintry weather which have occurred this winter the wireless and newspaper reports have described fog and wintry conditions as general, the only places specifically mentioned at various times as being free from such conditions being places in the south of England, particularly on the coasts. During the whole of this time, at Penmaenmawr, we have had no fog; snow on one occasion for a few hours only; frost perhaps four or five times, and only once lasting after breakfast time, and never more than a few degrees. There have also been a large number of bright sunny days.

"It seems hardly fair that this state of affairs on the North Wales coast should be passed over without comment, and that this district should be included in the general North Wales weather reports, which apply almost entirely to the inland mountainous districts. We are trying to obtain recognition of the fact that a portion of the North Wales coast enjoys a climate entirely different from the rest of North Wales, and comparing favourably with any other winter climate in the kingdom."

AN ARMLESS VIOLINIST

THE autobiography of Hermann Unthan, a German born without arms, is worth reading.¹ Thanks to the remarkable character of his father and to his own determination he learned, among many other things, to play the violin with his feet and finally succeeded in supporting himself as a vaudeville artist. The story of his travels makes an excellent story, and Unthan overcame his disability to such an extent that the reader, absorbed in following his adventures, will occasionally tend to forget its existence. There are a few crumbs for the anatomist and the surgeon interested in the training of the physically handicapped, but the chief attraction of the book is in the personality of its courageous author

CHILDREN IN TROUBLE

FRANKNESS in sex education is requisite for stemming sexual crime, not only by satisfying precocious curiosity and preventing early misconceptions of sex, but also by encouraging free discussion and sound thinking among adults. This is the wider aim of the Federation of Children's Moral Welfare Committees which, besides rescuing the victims of sexual perversion, provides speakers at meetings for mothers and social workers, and is willing to promote discussions in public-houses and working-men's clubs. The work is hindered by the passive resistance of uninformed people who regard it as

¹ Ujabb Szempontok a Tuberculosis Ellenküzdelemben, Budapest, 1935.

¹ The Armless Fiddler. By C. H. Unthan. London: George Allen and Unwin, Ltd. 1935. Pp. 287. 10s. 6d.

meddlesome. The Holborn, St. Pancras, and Hampstead committee, of which Dr. Alan Moncrieff is chairman, had 99 new cases to deal with in 1935; of these 33 were preventive, the remainder were nearly all the results of indecent assault. Some of the children, whose circumstances and temperament make it desirable, are sent to institutions, but the majority are kept under the supervision of workers. The committee has been able to ensure special accommodation for the children when they appear at police-courts and stations, and their examination by women doctors. There is a great need for voluntary workers, both men and women, and the hon. secretary will gladly receive offers at 7, Amptill-square, N.W.1.

ON BEING AN INVALID¹

THE musings of a musician whose practice of her art was hopelessly prevented by her condition of invalidism, make interesting reading, though many will be irritated with the extravagant terms of Monsieur Pierre Sanson's preface. The pages record the self-communings of the patient who appears to have been condemned to die by a famous professor in a few months or at longest in a year, but who none the less has survived for 15 years. The first section of the book entitled "The drama of the inner self" contains little that might not have been the experience of many chronically sick. The second part entitled "The drama of the environment" is more worth reading. Some of the sections on familiarity with disease, the obtuseness shown by the healthy towards it, the isolation from friendships, the risks of egoism, and the pain which may be inflicted upon the well by the ill contain much suggestive reading.

"CONTENTMENT"

Messrs. CIBA LTD., 40, Southwark-street, London, S.E. 1, have issued an ornamental calendar for 1936, adorned with a pictorial frontispiece of unintentional medical significance. It is a delineation of "a fine old English gentleman, one of the olden time," sleeping off his dinner, and the details supplied by the artist suggest why the well-to-do classes in the earlier days of the Georges had a shorter tenure of life than their descendants of to-day enjoy. The artist, Mr. W. L. Grace, has produced a costume picture of a hearty squire who has dined and wined according to the standards of his time, has laid down his churchwarden, has drunk a final glass of toddy, and is now sleeping off the results. The picture, which is thoroughly well painted, judging by an effective reproduction, is labelled "Contentment"; it ought to be labelled "Beware," for undoubtedly the self-indulgent gentleman is asking for much pathological trouble.

"CELLONA TECHNIQUE" is the name of a handbook published by T. J. Smith and Nephew Ltd. (Neptune-street, Hull), which describes the use of their Cellona bandages in the treatment of fractures and also in veterinary practice. The text mainly consists of selections from papers appearing in English medical journals, and nearly all the illustrations are reproduced from Mr. K. H. Pridie's article on plaster technique, published in THE LANCET last autumn (1935, ii., 680 and 732). The Cellona bandage contains 90 per cent. (by weight) of plaster-of-Paris; it is moistened in about 10 seconds and sets firm in 5-10 minutes. The standard widths are from 1 to 6 inches, and in addition Cellona plaster slabs, Cellona lacquer (for waterproofing), and Cellona hook tape are obtainable. The handbook concludes with an informative article on fracture treatment taken from the *Medical Annual* of 1935.

THE DENMAN THUMB-GRIP DEVELOPER is held in the closed hand in such a way that a spring knob

at one end is pressed inwards by the thumb. This exercises many muscles besides those of the thumb and finger, and it is claimed that nervous control as well as strength of hand and arm can be increased by keeping a pair in the pocket and gripping them occasionally. The training indeed may be helpful for golf or other games; but the producers (Denman Products Ltd., 169, Regent-street, London, W. 1) are perhaps unduly hopeful when they go on to suggest that the mental and physical concentration obtainable will "rebuild shattered nerves."

UNDER the title, "Suggested Standards for Milk Foods in Infant Feeding," Messrs. COW AND GATE LTD. (Guildford, Surrey) issue an attractive account of their aims and methods. They point out that their foods are prepared from Somerset and Dorset milk, and sold in sealed and dated tins. Poor or dirty milks produce powders which are low in solubility and high in acidity and do not keep well, and the Cow and Gate booklet describes the bonus schemes, farm inspections, and continual testing which ensure that the 9 million gallons used by the firm are fully satisfactory. Prepared by the "improved roller process" the powder is exposed to heat treatment at 98° C. for less than 3 seconds, and contains on an average 250 international units of vitamin D per pint of reconstituted milk, none being added artificially. Particulars are given of the 18 forms of dried milk manufactured, ranging from the standard full-cream and half-cream powders to such preparations as Caprolac, a goat's milk powder recommended for infants intolerant of cow's milk. Members of the medical profession are invited to visit the factories.

Births, Marriages, and Deaths

BIRTHS

- FOX.—On Jan. 8th, at Guernsey, the wife of Dr. Maurice D. Fox, of a daughter.
FRANKLIN.—On Jan. 15th, at Devonshire-place, W., the wife of Richard H. Franklin, F.R.C.S. Eng., of a son.
O'RIORDAN.—On Jan. 15th, at Plymouth, the wife of Surgeon Commander T. J. O'Riordan, R.N., of a son.
SNOW.—On Dec. 20th, at Poona, the wife of Captain J. E. Snow, R.A.M.C., of a son.
STEEL.—On Jan. 20th, at Hillingdon, Middlesex, the wife of Dr. W. Arklay Steel, of a son.
WILSON.—On Dec. 3rd, at Sydney, Australia, the wife of Dr. Harold Wilson, of a daughter.

MARRIAGES

- BLACK—CHRISTMAS.—On Jan. 17th, at St. Mary-le-Strand, Charles Black, M.B., Ch.B. Glasg., of Alexandria, Dumbartonshire, to Mary Elizabeth, daughter of Mr. John Christmas, Blythwood, Enfield.
DAY—BAILEY.—On Jan. 11th, at Jullundur, Punjab, India, Capt. Peter Leigh Day, R.A.M.C., to Jean Metcalfe Bailey.
MCMULLAN—WARD.—On Jan. 9th, at the Priory Church, Great Malvern, William McMullan, L.R.C.P., D.P.H., to Rosamund Mabel, only child of Mr. A. H. Ward, O.B.E., Great Malvern.
STEVENS—DAVIS.—On Jan. 11th, at St. Mary's Church, Twyford, T. Russell Stevens, F.R.C.S. Eng., Dorchester, only child of Thos. G. Stevens, F.R.C.S., to Enid, younger daughter of Mr. Stanley Davis.
SWAN—WHITE.—On Jan. 14th, at Ballymore Parish Church, Tandragee, Dr. William David Swan, son of the late Mr. John Swan and of Mrs. Swan, Ballyshannon, to Dr. Elizabeth Barrington White, younger daughter of the late Mr. T. H. White and of Mrs. White, Orange Hill, Tandragee.

DEATHS

- BERNARD.—On Jan. 19th, at Fishponds, Bristol, Claude Bernard, M.R.C.S. Eng., aged 67.
BOND.—On Jan. 18th, at Woodbridge, Suffolk, of pneumonia, Bertram William Bond, M.B. Durh., M.R.C.S. Eng., aged 67.
DOUGLAS.—On Jan. 20th, at Buckingham-gate, S.W., Stewart Ranken Douglas, F.R.C.P. Lond., F.R.S., youngest son of the late James Alexander Douglas.
FISHER.—On Jan. 10th, at Oreston, near Plymouth, Herbert Wortley Fisher, M.R.C.S. Eng., son of the late John Fisher, Inspector-General R.N., aged 59.
VERNON.—On Jan. 19th, at a nursing-home, Ethel Miller Vernon, M.D. Lond., of Millbank, S.W., eldest daughter of the late Thomas Heygate Vernon.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

THE SURGERY OF CORNEAL GRAFTS

WITH LATE REPORTS

BY B. W. RYCROFT, M.D. St. And., F.R.C.S. Eng.,
D.O.M.S.

ASSISTANT SURGEON AND PATHOLOGIST TO THE ROYAL EYE HOSPITAL, LONDON; OPHTHALMIC SURGEON TO THE KING GEORGE HOSPITAL ILFORD; LATE HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND

(WITH ILLUSTRATIONS ON PLATE)

THE latter half of the nineteenth century saw a rapid expansion in all branches of ophthalmic surgery, largely stimulated by the successful work of von Graefe and his pupils, and at this time great interest was taken in early experimental keratoplasty. Although de Quengsy in 1789 had mooted the idea of a transparent glass implant in the cornea, it was not until 1824 that Reisinger attempted to graft living cornea in rabbits. He was not successful, and further attempts by Mulbauer and Durr in 1877, also using rabbits, met with similar results.

A. von Hippel was the first surgeon to demonstrate, at the International Congress in Heidelberg in 1888, a successful case of corneal graft in a rabbit. He described two methods: (1) that in which a partial thickness of the cornea was employed (lamellar); (2) that in which the whole thickness of the cornea was removed (circumscribed penetrating) (Fig. I. *a* and *b*). He used a circular trephine of his own device but without any method of fixation of the graft. It is on this worker's pioneer technique that the modern operation of keratoplasty depends. The lamellar method, which appeared safer in those early days, was used by several workers, and the first successful case of human corneal grafting by it was demonstrated by Zirm in 1906, in a case of dense corneal scarring following a lime burn. Modifications followed in rapid succession. Lohlein in 1909 used a vertical strip of cornea together with attached conjunctiva. Wiener removed superficial scars and allowed the raw surfaces to epithelialise, but the method of partial keratoplasty was finally abandoned since the implants were not permanently transparent.

keratitis. Several patients were improved to a vision of 6/6. The technique of the operation constituted rigid preliminary aseptic routine, van Lint facial block, retrobulbar anaesthesia, and the Elschnig fixation suture (Fig. II.). A Hippel trephine was used to prepare the graft and the whole of the thickness without any bevelling of the edges was employed, the pupil being in a

FIG. I.—Von Hippel: (a) lamellar keratoplasty; (b) circumscribed penetrating with no special method of fixation.

state of miosis. The size of the trephine was 4-5 mm. Thereafter the graft was kept between layers of dry gauze and fixation was obtained by a bridle suture running over the graft; in 22 cases, flaps also had to be employed (Fig. II.). The conclusions which Elschnig reached were that the penetrating method of keratoplasty was the method of choice, that the blood group of host and donor had no relationship to the subsequent transparency of the graft, that the graft could be removed from an eye which was not necessarily healthy provided it was transparent at the time of removal, and that the younger donors provide the better grafts.

Within the last five years there have been many modifications of this method. Filatoff uses ribbon flaps of conjunctiva to keep the graft in place, having previously protected the lens and iris by a strip of celluloid inserted behind it. Egg membrane is also used as a protective. Tudor Thomas (Fig. III.) bevels the edge of the graft and employs a slightly larger trephine to cut the bed. Olive oil is used as a vehicle and protective dressing, and corneal

FIG. II.—Elschnig: Circumscribed penetrating keratoplasty with bridle fixation suture. Miosis.

FIG. III.—Thomas: Corneal fixation suture, bevelled graft. Miosis.

FIG. IV.—Castroviejo: Rectangular graft. Vertical flap.

About the year 1910 Elschnig and his assistants commenced a series of operations which in 1930 had reached a total of 172 cases. Their results, which have never been surpassed, removed the operation of keratoplasty from the experimental to the therapeutic stage. These workers claimed successes—that is to say, clear corneal grafts—in 22 per cent. of all cases and in 73 per cent. of cases of interstitial

sutures are used for fixation (Fig. III.). Castroviejo uses parallel knives and cuts a rectangular graft using conjunctival flaps for fixation (Fig. IV.). The procedures of Morax and Kraupa should be noted at this stage (Fig. V.). Morax employs auto-transplants from the same cornea. This is necessarily of the lamellar type, and there is an interchange of corneal discs so that the opaque disc is placed at the

periphery and a clear disc is placed over the nebula. Kraupa employing the circumscribed penetrating method rotates the graft, which is composed partly of scar tissue and partly of clear cornea. Rotation brings the clear segment of the graft into the pupillary line and

FIG. 5.—(a) Kraupa: Rotation of graft. (b) Morax: Transposition of graft. Lamellar method.

diverts the scarred portion to the periphery. Key had attempted to graft the whole of the cornea but without success.

The Author's Method

I employ the following method (Fig. VI.). A general investigation of the host and donor is undertaken; gross focal sepsis is removed and general disease eliminated; the Wassermann reaction in the donor must be negative. There must have been no active disease in the eyes for at least a year before keratoplasty can be undertaken. The usual preliminary cataract precautions are taken such as ensuring patency of the lacrimal ducts and sterility of the conjunctival sac; there must be no severe cough or prostatic obstruction. Preliminary treatment is carried out for one week, with four-hourly irrigations of hydrarg. oxycyanide lotion 1:8000, together with local ultra-violet radiation of three minutes' duration daily by the full spectrum of the mercury-vapour lamp. The projection of the eye is accurately measured and the response must be brisk. Retro-illumination determines the position of the pupil and the presence or not of gross lens opacities; this is important in determining the precise site for the graft. On the day before operation the state of the bowels is attended to in the usual way, and atropine is instilled at night into the host's eye. I have given up the use of miotics for reasons stated later. On the morning of operation Medinal grs. 7½ is given one hour before the projected time of operation. The patient is operated on in bed and not lifted on to an operating table.

OPERATION

The preparation of the site in the host and the enucleation of the donor's eye are begun simultaneously. Anæsthesia is obtained by 4 per cent. cocaine and retrobulbar injection of novocain with adrenaline so as to reduce the tension of the eye and prevent expulsion of the intra-ocular contents. Facial akinesis by the method of O'Brien is a routine procedure. In the host a complete flap is prepared circumscribing the limbus and separated well back to the equator of the globe. A purse-string suture (No. 1 black silk Mersuture) is inserted close to the edge of the conjunctiva in such a way as to render the aperture eccentric when tightened. A 4 mm. circular graft is delineated over the precise site of the pupillary aperture which has previously been determined and may have been marked on the nebula by methylene-blue (Elschnig), and the whole thickness of the cornea is cut through. In early cases I practised the shelving method of Tudor Thomas but recently I have abandoned this because there is little risk of losing the disc, and the shelf of up to 1 mm. reduces the available portion for vision of the 4 mm. graft to 2 mm. posteriorly and there is

a risk of Descemetitis covering this small aperture later. During these manœuvres the eye is constantly irrigated by normal saline at body temperature, and when the graft is cut through in one portion the aqueous is slowly evacuated, and the section completed by scissors and fine protected forceps. The same procedure is carried out in the enucleated eye using Tudor Thomas's apparatus for holding the globe.

The graft is then transferred to normal saline lotion at body temperature, and from there to the bed by means of a lens spoon, care being exercised to see that it is not turned upside down. It is manœuvred into position by means of the iris repositor, the assistant at the same time gradually tightening the purse-string suture so that the graft gradually disappears from view as the conjunctiva closes over it. When the conjunctiva is tied off and allowed to fall back the graft is held securely in position by the natural strap over the cornea. No suture touches the graft since it is entirely covered by conjunctiva. A retention stitch fixes the upper lid to the cheek and ordinary postoperative cataract routine is instituted.

Aspirin, grs. 10, is given after the operation, and as a rule there is no pain and very little discomfort. The eye is not dressed for three days, after which the graft usually appears opaque and can be dimly seen through the widening conjunctival aperture. At the end of the first week more of the graft is visible, and it is slowly beginning to clear; on the tenth to the fourteenth day the stitch either cuts out or is removed and the conjunctiva slides back. Atropine mydriasis is continued from the first dressing. It is of importance to keep the patient in bed for at least a month, since the linear scar is weak and there is a tendency to prolapse if the patient in his enthusiasm attempts to do too much.

FIG. 6.—Rycroft: Circumscribed penetrating keratoplasty. Complete conjunctival flap. Mydriasis.

INDICATIONS

Indications for the graft of a cornea are clearly defined.

- (1) Vision must be reduced, to perception of hand movements, by a corneal scar.
- (2) Uveal tissue must not adhere to the scar; this must be separated off before a graft is undertaken.
- (3) The pupillary aperture must be bright and mobile by retro-illumination, although successful cases of graft have subsequently had a cataract removed.
- (4) Glaucoma must be absent.
- (5) The projection of light must be accurate and brisk.
- (6) There must be an absence of disease in the host and of syphilis in the donor.

Suitable cases result from chemical burns, healed interstitial keratitis and corneal ulceration without iris prolapse, and the definition of a successful case is that the graft is in place one year after operation and has retained transparency throughout that year with a maintenance of vision. Filatoff put the period of nine months. Donor grafts may be obtained from

cases of sarcoma, detached retina, absolute glaucoma without oedema, old iritis, and cases of recent injury.

OPERATIVE COMPLICATIONS

1. *Prolapse*.—In one case a large graft of 6 mm. was used and a prolapse occurred at the end of the first week. This was excised satisfactorily but the transparency of the graft was affected by the trauma. With 4 mm. grafts there has been no prolapse, and it would appear that a larger wound takes longer to heal and the risk of prolapse is correspondingly greater. Furthermore I now employ mydriasis as the preventive before, during, and after the operation, since with the loss of aqueous the pupil contracts in any case and protects the lens so that miosis seems to be unnecessary; it appears to favour incarceration of the iris in the wound two or three hours after operation.

2. *Difficulty of fixation of the graft*.—I now use a complete graft without bevelling of the edges following the method of Elschmig, who had only 1 misplaced graft in 172 cases. Furthermore this shelving tends to make the accurate fixation of the graft difficult and certainly diminishes the posterior visual aperture of the cornea and increases the linear scar area. Corneal sutures predispose to a localised opacity and cross stitches may interpose themselves between the lips of the graft (Castroviejo). The object of the complete conjunctival flap as described is to give a uniform pressure over the graft with an absence of irritating foreign substances. The swelling of the graft rapidly fixes it in position in the cornea, and the same size of trephine is used for host and donor.

3. *Sepsis does not occur frequently*.—Elschnig gives one case of necrosis in his series, and with careful preliminary technique it is possible to avoid this, especially if the site of the graft is carefully covered by conjunctiva.

4. *Opacification of the graft*.—There are three types of opacity. The first comes on during the first week, and is the result of the imbibition of aqueous humour into the substantia propria; it rapidly clears up towards the end of the first week. The second is due to vascularity from the spread of superficial vessels towards the end of the second week; this takes longer to clear but is not permanent. The third opacification comes about the end of the first fortnight, and is due to a failure of nutrition in the graft, and is permanent. In successful cases the area outside the graft also clears to a certain extent.

The Use of Animal Grafts

For many years the earlier workers were hampered by the limitations of their material. Von Hippel employed grafts from rabbits and dogs without success. This has been often repeated with the same results up to the present day, and it appears quite definite that grafts from animals cannot be successfully employed in the human. Grafts from cadavers may be employed provided they are taken within an hour of death as described by Filatoff. Magitot has kept a graft transparent for four weeks in hamolysed serum. Salzer and Ortin after many experiments have come to the conclusion that autotransplants—i.e., transplants from the same person or same cornea (Kraupa, Morax)—are best, that homotransplants from the same species may be successful, but that heterotransplants from different species are never successful. Tudor Thomas has reported the use of devitalised corneal tissue in rabbits and has pointed out that there is a general firm union with the thinning of the linear scar and very little reaction.

Illustrative Cases

The following three cases are examples of corneal grafts after six, nine, and twelve months.

CASE 1.—A man, aged 52, in 1930 had a severe attack of interstitial keratitis of the right eye and was treated by Mr. N. L. Pines who recommended the removal of unerupted wisdom teeth. The result of this operation was that the acute condition subsided, and in 1932 the eye became quiet with a vision of perception of light (Fig. VII. a on Plate). In May, 1935, keratoplasty was decided upon, although the condition was unilateral, and preliminary investigation was undertaken. For many weeks conjunctival culture showed *Staphylococcus aureus* until finally, by vigorous ultra-violet radiation, silver nitrate, and the usual applications, a clean culture was obtained. A 4 mm. graft was employed, the donor being a woman who had suffered complete retinal detachment and old iritis. The patient has made an uninterrupted recovery and six months later is able to go about by the aid of this eye alone which has vision of 6/60 and a full field. Colour vision is normal, and he is able to read the headings in a newspaper. The cosmetic result is excellent and the graft is steadily clearing (Fig. VII. b).

CASE 2.—A woman, aged 49, has suffered since the age of 7 from ulceration of both eyes and was treated for some years by curettage of the cornea and instillations of dionine. Since 1930 there has been no treatment. On admission to hospital for keratoplasty both corneae showed a central nebulae of medium density; vision was perception of light, and in each eye there was no organic disease of the patient. The tension of the right eye was 30 and of the left 26, and the left was accordingly chosen for corneal graft. With the technique described, using a 6 mm. graft, keratoplasty was carried out. Five days after the operation the patient was able to see a dim form in a bed across the ward, to make out the windows of the ward, and to see chimneys on adjacent houses. But on the tenth day there was a prolapse of the iris which had to be excised. Thereafter the transparency of the graft failed and the vision to-day has been reduced to counting of fingers, which was better than it was before the operation.

CASE 3.*—The third case was shown to the section of ophthalmology, Royal Society of Medicine, in January, 1935. The patient was a woman, aged 48, who had had the right eye removed for tuberculous keratitis, and whose left cornea showed healed opacity which had reduced her vision to perception of light (Fig. VIII. a on Plate). She had been certified for the Blind Register and had ceased treatment in November, 1934. Complete investigation was carried out, and a 4 mm. corneal graft was obtained from an accident case and inserted into the patient's cornea by the above method. Convalescence was uneventful, and we demonstrated the case at a vision of 6/24 with correction and J 6 (Fig. VIII. b). One year after operation the graft has still maintained its transparency; there is a good deal of thickening of Descemet's membrane on the posterior corneal surface but the pupillary gap remains wide enough to afford a vision of 6/36; the anterior chamber and iris are seen to be normal. There is no ectasia of the scar and the tension is normal. Vascularisation is absent except for a few superficial conjunctival vessels.

During the last year the patient has gone about the streets on her own and made bus journeys alone. She is able to read newspapers and write good manuscript. She attends and enjoys the cinema, and is able to do her own housework. For reading fine print, J 4, she employs telescopic spectacles, but for ordinary purposes the unaided eye is used. She reports that she finds it difficult to express her feelings at being able to see again after having resigned herself to a life of blindness.

I have received much valued assistance from the senior house surgeons at the Royal Eye Hospital, Mr. G. Handelsman and Mr. R. H. Rushton who were responsible for the preliminary investigations and for assistance during the actual operations; to them I am gratefully indebted.

* The history of this patient up to last March has been recorded in the British Medical Journal (1935, i., 919).

EFFECT OF SEX HORMONES ON THE PROSTATE OF MONKEYS

BY S. ZUCKERMAN, D.Sc. Lond., M.R.C.S. Eng.

BEIT MEMORIAL RESEARCH FELLOW; AND

A. S. PARKES, Sc.D. Camb., F.R.S.

(From the Department of Human Anatomy, Oxford, and the National Institute for Medical Research, London)

I.—The Effects of Male Hormone

ALTHOUGH a beginning has been made in the clinical use of male hormone preparations, our experimental knowledge of the effects of the hormone on the accessory reproductive organs relates only to small rodents. The present investigation on immature monkeys provides information about corresponding effects on accessory reproductive organs homologically similar to those of man.

Such an investigation does not appear to have been made as yet, and indeed there have been practically no studies even of the secondary sexual characters of monkeys and apes, in many species of which they are exceptionally well marked. Antonius¹ reports that the very conspicuous cape of hair of male hamadryas baboons disappears, and the pelage changes to the female type after castration. We can confirm his statement on the basis of a similar experiment of our own, but apart from these two observations, we know of none that relates to the endocrinology of the testis in subhuman primates.

INVESTIGATION

Material.—Seven normal immature male rhesus monkeys (*Macaca mulatta*), whose weights and approximate ages are given in Table I, were used in this study. One was injected daily with 10 capon units* of "Enarmon" urine concentrate, for which we thank Dr. Itoh, Teikokusha Institute, Kawasaki. Three were injected with an oil solution of "synthetic" androsterone,² and three with an oil solution of "synthetic" androstanediol³ (di-hydroandrosterone). (See Table I.) For both these prepara-

* At the time this assay was made no standard of reference was available, but 1 "capon unit" as then used by us is now known to correspond almost exactly to the activity of 100 γ of androsterone, the prospective international unit of male hormone activity.

tions we are greatly indebted to Prof. L. Ruzicka and Messrs. Ciba Ltd.

An extensive control series of normal animals was available.

TABLE I

Administration of Male Hormone to Immature Male Rhesus Monkeys

				5 "		

EXPERIMENTAL RESULTS

External changes.—Swelling and coloration of the skin of the external genital organs, anus, and surrounding areas, such as develop during injection of oestrone, did not occur during any of the present experiments with male hormone. The external genitalia were unexceptional in all the monkeys except M.M. 53, which differed from the other experimental animals in that its testes at autopsy were at the base of a well-developed scrotum. Since, however, the testes were still undescended in M.M. 78, in which injections of androstanediol were continued for longer than in the case of M.M. 53, it is difficult to ascribe the position of the testes in the latter to the injections, and it is possible that the animal had already reached the age for testicular descent.

There was a suggestion in the behaviour of M.M. 78 that its responses became more aggressive, and its social position in the cage, which it occupied with two other males of the same age, more dominant towards the end of the treatment.

Internal changes.—With the exception of M.M. 10, the prostate and seminal vesicles of all the injected animals are larger than those of the normal controls. The seminal vesicles show the usual characters associated with the administration of male hormone in rodents⁴ and need not be discussed here. Essentially they comprise rapid glandular development, and a relative and parallel decrease in the fibromuscular tissue (Fig. 1). The degree of response roughly corresponds to the number of units administered.⁵

The prostatic changes are confined to the prostatic glands proper and to their fibromuscular stroma, and,

as with the seminal vesicles, the degree of response is roughly proportional to the number of units administered. The muscle cells and nuclei are more swollen than is normal, and mitoses are frequent in the stroma, which is also unusually vascular.

The prostatic glands, especially in those specimens which had been injected with androstanediol, are much larger than normal. The increase in their size can be attributed mainly to an increase in the size of the cells of the glandular epithelium. These cells, especially in the best developed glands, are much larger and more regularly columnar than in the normal, with oval basal nuclei and a conspicuous inner zone of cytoplasm. The cells do not characteristically show a central paler zone in the inner cytoplasm such as is described in the rat after treatment with male hormone,⁶ but this may be due

to the fact that no special technique was followed in the staining of the sections, which were treated with Meyer's hæmalum and eosin. Although the glands are more open than in the controls, and contain more secretion, they are not in any specimen as dilated as in fully mature male primates. Moreover, although there are numerous mitoses in the glandular epithelium, it is doubtful whether the number of individual glands is greater than in the control material (Fig. 2).

In none of the experimental animals are there any changes in the utricular epithelium, epithelium of the terminal parts of the common ejaculatory ducts, or epithelium of the dorsal part of the lower half of the prostatic urethra, tissues which respond to œstrone.

CONCLUSION

The essential changes occasioned by male hormone in the seminal vesicles and the prostate of the

immature monkey are similar to those which occur in the true prostatic tissue of rodents—i.e., the hormone promotes rapid growth in the size of the organs by acting both on their fibromuscular stroma and on their individual glandular elements, which are rapidly transformed to a mature type. In its lack of influence on the epithelium of the uterus masculinus, which responds to œstrone, male hormone obeys the principle laid down by Moore and Price⁷ that "gonad hormones stimulate homologous reproductive accessories, but are without effect upon heterologous accessories"

The small number of specimens studied and the difference in the treatment of the various animals make it difficult to compare the relative potencies of the various preparations used, but the maturest

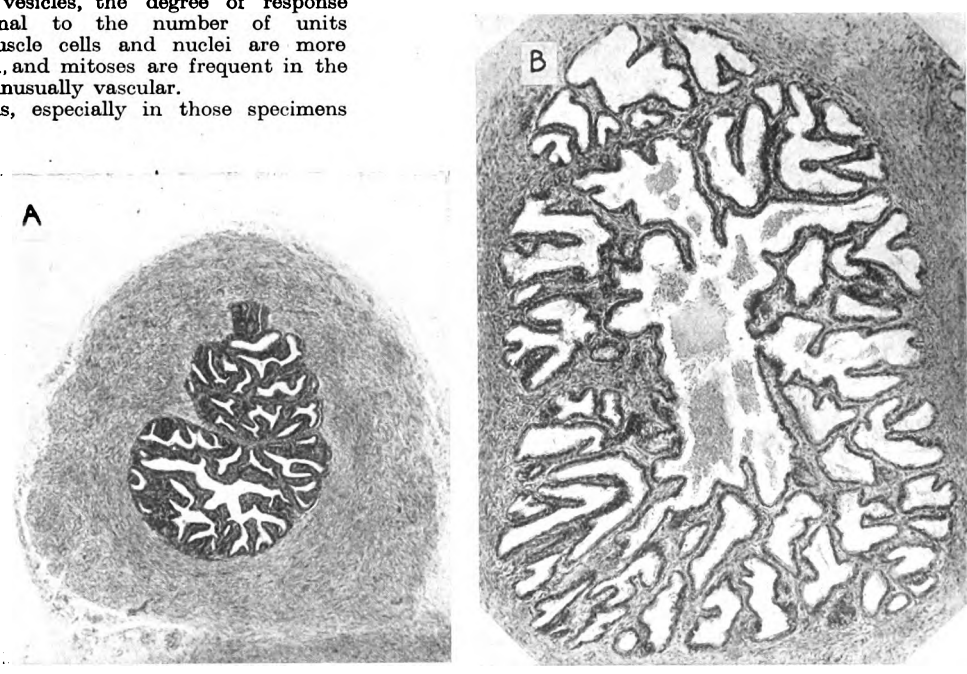

FIG. 1.—(A) Seminal vesicle of immature normal rhesus monkey (MM. 11). (B) Seminal vesicle of immature rhesus monkey (MM. 53) after injection of androstanediol (see Table I.). (× 47.)

FIG. 2.—(A) and (B) prostates corresponding to seminal vesicles in Fig. 1. (× 157.)

prostates were those of the animals injected with androstanediol. The animal injected with enarmon, on the other hand, showed very few changes. Although the activity of enarmon on rats per capon unit is at least three times that of crystalline androsterone, the lack of effect in the present instance is not surprising, since the total amount of enarmon injected could not have equalled in potency much more than 30 mg. of androsterone.⁸

II.—Suppression of Effects of Œstrone by Simultaneous Administration of Male Hormone

The possibility that the epithelial changes induced by Œstrone in the prostate of monkeys⁹ may throw light on the aetiology of glandular hyperplasia of the prostate in man makes it urgent to inquire whether or not these changes in the monkey can be inhibited by male hormone, in the same way as similarly induced changes in the prostate of mice.¹⁰⁻¹² The immediate importance of this problem lies in the homological similarities of the monkey and human prostates, and in the present uncertainties as to the true relationship of the organ called prostate in mice to the primate organ of the same name. The general significance of the problem is complicated by the doubt as to the nature of the Œstrogenic substance found in the male mammal. Esterified Œstrone is certainly excreted by the stallion, but whether or not it is by other male mammals is unknown. Biological examination of testis extracts¹³ suggests strongly that the Œstrogenic substance elaborated by the bull is neither Œstrone nor Œstriol. Moreover, one of the two compounds possessing male hormone activity which have been isolated from human male urine (trans-dehydroandrosterone) is Œstrogenic (Butenandt¹⁴), and the Œstrogenic property of human male urine may be partly or wholly accounted for by its presence. Whether or not trans-dehydroandrosterone can produce prostatic effects in the male primate similar to those of Œstrone remains to be seen. Our first experiment has proved negative (MM. 80).

The present investigation deals with a group of monkeys in three of which the effects of Œstrone were undoubtedly inhibited by means of male hormone.

INVESTIGATION

Material.—Five immature male rhesus monkeys, whose weight and approximate age are given in Table II., were used. Two received an oil solution of "synthetic" androsterone as well as an oil solution of crystalline Œstrone. The remaining three animals received an oil solution of androstanediol (di-hydroandrosterone) which is three or four times more potent on castrated rats than androsterone, in addition to the Œstrone. These two male hormone compounds were available through the courtesy of Prof. Ruzicka and Messrs. Ciba Ltd.

Injections were made once daily for the periods indicated in Table II., and autopsies were made on the day after the last injection. Preparations from normal male rhesus monkeys and from male monkeys injected with similar amounts of Œstrone alone and with similar amounts of male hormone alone were available as controls.

EXPERIMENTAL RESULTS

External changes.—Only MM. 55 presented any clear evidence that the external effects of Œstrone had been suppressed by the male hormone. The other four animals all showed marked œdema of the scrotum and anus, as well as swelling and coloration of the surrounding skin. In MM. 55 the swelling was practically restricted to the anus, and in view of the internal condition (see below) there seems little doubt that the androstanediol with which this animal was injected had in some way prevented the Œstrone from producing its usual external effect.

Prostatic and urethral changes.—The prostate, uterus masculinus, and upper urethra in MM. 32 and MM. 33 are not different histologically from corresponding tissues taken from animals injected with Œstrone alone. In both cases the prostate is much larger than in normal animals of the same age, and there is considerable stratification of the utricular epithelium. The general prostatic stroma appears to be relatively increased in amount, and the prostatic glands in no way resemble the glands of monkeys injected with male hormone alone. The urethra also shows the typical stratification induced by Œstrone.

MM. 55, MM. 57, and MM. 74, on the other hand, show the characteristic prostatic changes associated with the administration of male hormone alone, and do not present any specific features which could be ascribed to the action of Œstrone. Thus the uterus masculinus in all three is normal in appearance, its epithelium varying between one and three cells deep (Fig. 3). Similarly, the urethral epithelium is normal and completely unlike the heavily stratified epithelium found in the urethra following the injection of Œstrone alone.

On the other hand, the prostatic glands are much more conspicuous than those of normal animals of the same age. The individual glands are larger and more distended, and characteristically lined by regularly set large columnar cells with basal nuclei. Mitotic figures are numerous, both in the glandular tissue and in the fibromuscular

TABLE II

Simultaneous Administration of Male Hormone and Œstrone to Immature Male Rhesus Monkeys

No. of animal (M.M.)	Body-weight	Approx. age in months.	Amount of Œstrone daily (γ).	Nature of male hormone.	Daily amount.	Days injected.	Condition of uterus masculinus.
32	(g.) 2700	24	200	Andro-sterone.	(mg.) 2.5	16	Extensive stratification.
33	2700	24	200		2.5	16	
55	2500	21	100	Andro-stanediol.	5.0	14	Normal.
57	2800	25	100		5.0	14	
74	2580	28	100		5.0	14	

stroma. As with most male monkeys injected with Œstrone and male hormone, either separately or together, the prostate is much bigger in these three animals than in normal controls of the same weight and age. The prostate of MM. 74 is almost twice as large as that of a control animal slightly heavier than itself.

DISCUSSION

The absence in MM. 55, MM. 57, and MM. 74 of any of the characteristic prostatic epithelial changes induced by Œstrone can leave little doubt that androstanediol in the proportions given (50 parts by weight to 1 part by weight of Œstrone) is able to inhibit the prostatic effects of Œstrone. Although it is well known, as we have already noted, that androstanediol is a more potent form of male hormone than androsterone, our experiments do not permit the conclusion that it is more potent in suppressing the effects of Œstrone, since we employed relatively four times as much androstanediol as androsterone per unit of Œstrone. It is also uncertain whether androstanediol has a specific effect in suppressing the changes induced by Œstrone. Probably other compounds of the androsterone-testosterone series would have the same effect if given in adequate amounts. There is also some indication that progesterone may have a similar antagonistic effect (see below). The actual mechanism by which Œstrone is prevented from exercising its normal effects by androstanediol is a matter for conjecture, and it is of interest that the hormone did not suppress all the effects of

œstrone in our experiments. Animals MM. 57 and MM. 74 showed prominent external changes, and this implies that the œstrone threshold of the skin of the scrotum and of the surrounding parts of the rhesus monkey is lower than that of the prostate. It may, however, be noted that the seminal vesicles of the present experimental

group of monkeys roughly corresponded, from the point of view of suppression of œstrone effects, to the prostates.

Our data do not allow any clear inference as to any possible synergistic action of œstrone and male hormone. In those cases in which the effects of œstrone were dominant (MM. 32 and MM. 33) there were no changes which could be clearly ascribed to male hormone, and the reverse also holds (MM. 55, MM. 57, and MM. 74). The only effect common to both groups of animals in our present experiments is the increase in the size of the prostate itself and in the amount of fibromuscular stroma, and this is an effect also obtained when either œstrone or male hormone is given separately. In failing to demonstrate a synergistic relation between œstrone and male hormone, our relations are in harmony with those of Moore⁶ and Callow and Deanesly⁸ on the seminal vesicles and prostate of rats, but in some disagreement with observations made by Freud,¹⁵ Korenchevsky and Dennison,¹⁶ and Overholser and Nelson.¹⁷

Male hormone is not only able to inhibit the prostatic effects of œstrone when injected simultaneously with the latter; as the following experiment shows, it can also cause the disappearance of

FIG. 3.—(A) Uterus masculinus of rhesus monkey (MM. 77) receiving 100 γ œstrone daily for 14 days. ($\times 47$.) (B) Uterus masculinus of rhesus monkey (MM. 55) receiving 100 γ œstrone plus 5 mg. androstanediol daily for 14 days. ($\times 47$.)

already established prostatic changes induced by œstrone, even in spite of the latter's continued administration.

Two immature rhesus monkeys, MM. 81 and MM. 82, both 3 kg. in weight and about 2½ years old, were injected with 100 γ of œstrone daily for 67 days. From the 29th day of the experiment, by which time the prostatic changes induced by œstrone would have been well established, until the end of the experiment 39 days later, MM. 81 was given, in addition to the œstrone, 5 mg. of androstanediol daily. The first effect of this additional treatment was the diminution of the swelling and coloration in the circumgenital and circumanal skin, which was very pronounced in both animals after the first 28 days of œstrone. As the experiment proceeded these external changes became less and less conspicuous in MM. 81, and at the close the scrotum and surrounding skin were almost normal in appearance. On the other hand, the external response became more and more extensive in MM. 82, which was on œstrone alone.

The prostates of the two animals showed corresponding differences. That of the monkey which had received only œstrone showed very advanced changes induced by this treatment.⁹ For example, the uterus masculinus had grown enormously, and its wall had become excessively thick. In contrast to this, the prostate of the animal which had been given male hormone as well was manifestly healthy, and provided an excellent picture of the effect

male hormone has on the prostatic glands of the immature monkey. Practically no sign remained of the changes which must have been produced during the first 28 days of the experiment when œstrone alone was administered, nor was there any evidence that the œstrone injected during the last 39 days had had any effect. Except at its blind tip and at its mouth, where the epithelium was slightly deeper than normal, the uterus masculinus was no different from that of an unjected animal. The urethral epithelium, too, though still

FIG. 4.—(A) Uterus masculinus of rhesus monkey (MM. 49) receiving 50 γ œstrone plus 300 γ progesterone daily for 14 days. ($\times 47$.) (B) Uterus masculinus of rhesus monkey (MM. 65) receiving 50 γ œstrone plus 1 mg. progesterone daily for 14 days. ($\times 47$.)

tions so far. A sixth tumour was found in a castrated male mouse of this strain which had been painted with keto-hydroxy-œstrin for 19 weeks. An apparently paradoxical result is that none of the females of this strain developed a tumour after treatment with œstrin lasting for more than 6 months, although tumours appear in 60-70 per cent. of untreated females of this strain when they are over six months old. Of the mixed strain, neither the males nor the females have so far developed a tumour.

The results confirm the observations of Lacassagne,¹ who first demonstrated the appearance of mammary carcinoma in male mice by injections of œstrin. While these experiments were in progress, Burrows² has also recorded the development of mammary cancer in 2 male castrated mice out of 20 mice of a mixed strain, after painting the skin with œstrin for a period of 25 weeks and 41 weeks respectively. No tumour had appeared in 110 male non-castrated mice of the same strain, which showed a very low incidence of spontaneous mammary tumours in the female. In our experiment, the œstrin-painted mice

demonstrates equally clearly the importance of the extrinsic carcinogenic factor, in this case œstrin.

4. The sensitiveness of the male mamma in its carcinogenic response to œstrin, contrasted with the great insensitiveness to œstrin of the female mamma in animals of a pure strain in which the female mamma develops cancer spontaneously in a very high percentage, suggests that either the female organism is able to destroy effectively the excess of œstrin administered experimentally, or that the carcinogenic response of the mammary epithelium depends on an indirect and not on a direct interaction between œstrin and the cells.

The second object of this communication is to record the occurrence of changes after the prolonged administration of œstrin which extend beyond the sex organs and which have not been recognised previously. It was found that an outstanding change in mice treated with œstrin over a prolonged period was the complete disappearance of fat, in fact a condition of cachexia. There were also extensive degenerative changes in the adrenal (Fig. 6), with active secretion of adrenaline by the medulla, and a hypertrophy in the islets of Langerhans. These

EXPLANATION OF PLATE

FIG. 1.—Naked-eye view of pituitary gland of normal male mouse, showing size and relation of gland to the optic nerves.

FIG. 2.—Naked-eye view of pituitary gland of male mouse of D.Z. strain after 6 months' painting with œstrin (Ref. No. 202 in Table of text), showing intense congestion of the pars anterior and compression of optic nerve.

FIG. 3.—Section through anterior lobe of gland illustrated in Fig. 2, showing large hæmorrhagic areas.

FIG. 4.—Section through anterior lobe of normal mouse pituitary at a magnification slightly higher than in Fig. 3, to illustrate degree of enlargement of the adenoma.

FIG. 5.—Section through testis of a mouse after 6 months' application of œstrin, showing absence of spermatids and spermatozoa, and arrest of the process of cell division, so that practically all the cells are immobilised in mitosis.

FIG. 6.—Adrenal gland of a male mouse after 5 months' application of œstrin. Osmic vapour fixation. Round masses of degenerating cells are conspicuous around the medulla. In a more advanced stage they almost completely replace the medulla. There is active secretion of adrenaline in the medulla.

showed the extensive changes in the uterus and vagina in the females and the atrophy of the testicles in the males which have been described previously. Scrotal hernia was observed to occur only in the males of the high cancer strain. The histological examination of the testis disclosed a condition which does not appear to have been described previously: œstrin inhibits the formation of spermatids and of spermatozoa and at the same time arrests division in the primary and secondary spermatocytes, the great majority of which present themselves in the process of cell division (Fig. 5). Œstrin therefore appears to arrest the process of cell division in the testis.

These results will be described in greater detail in a separate publication. For the present we wish merely to emphasise the following conclusions as being of general significance:—

1. Œstrin is absorbed by the unbroken skin without producing in it any carcinogenic effect.

2. Unlike the other carcinogenic substances so far studied experimentally, the carcinogenic effect of œstrin is restricted to a tissue remote from the site of application of the carcinogenic agent, but possessing a specific physiological sensitiveness to it. The action of œstrin resembles that of the other carcinogenic agents in producing first a hyperplasia of the tissue in which the cancer subsequently develops—the precancerous condition—and in the long period of time necessary to induce cancer.

3. The striking difference between the carcinogenic response to œstrin of male mice belonging to two different strains demonstrates clearly the importance of the factor "susceptibility," which in this case is genetic in origin, in the aetiology of cancer. The fact that cancer develops here in a site in which it never appears spontaneously

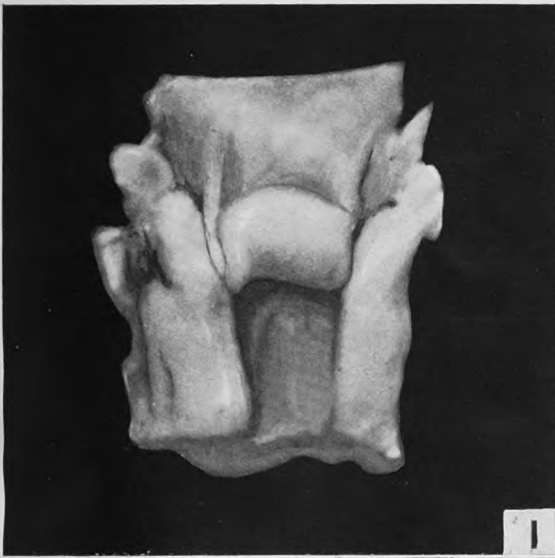

effects will be described in greater detail in subsequent publications.

The spleen was sometimes reduced to a thin red ribbon, and the thymus was atrophied. The changes in the testis have been mentioned above. These changes suggested a general effect of œstrin, and further search led us to a systematic examination of the pituitary. During this experiment we have so far examined the pituitary gland of 12 mice treated with œstrin over a prolonged period. Of these, only 1 gland was normal to the naked eye, 8 were macroscopically enlarged without an alteration in the general shape of the organ and without gross pathological lesions in the gland, and 3 were definite adenomatous tumours, nodular, round, deeply congested and hæmorrhagic, and from five to ten times the size of the normal gland, so that the tumour extended over the optic nerves and in one case (No. 217) compressed them, producing degenerative changes in the nerve (Fig. 2). Even with the naked eye it could be seen that the changes affected mainly, if not entirely, the anterior part of the gland. The experimental details concerning the three animals in which these tumours were found are given in the following Table:—

Ref. No.	Strain.	Sex.	Treat-ment with œstrin.	Prepara-tion.	Condition of mamma.
202	L.Z.	Male.	25 weeks.	a-folli-culin.	Mamma carcinoma.
215	Mixed.	Male, castrated.	44 "	"	Mamma well developed but no carcinoma.
217	D.Z.	"	19 "	Keto-hydroxy-œstrin.	Mamma carcinoma.

DRS. CRAMER AND HORNING: EXPERIMENTAL PRODUCTION OF PITUITARY TUMOURS AND OF MAMMARY CANCER BY PAINTING THE SKIN WITH ŒSTRIN

MR. RYCROFT : CORNEAL GRAFTS

MR. HOSFORD : KÜMMELL'S DISEASE

MR. MONTEITH : BEDSIDE RADIOGRAPHY FOR A FRACTURE

MR. COSBIE ROSS : LIPIODOL IN SURGERY OF BILIARY PASSAGES

The pituitary tumours were found, therefore, in mice of both strains and in mice with and without the presence of a mammary cancer.

The detailed histological examination of the pituitaries has not yet been completed, but a preliminary microscopic examination of the three adenomata has shown extensive hæmorrhages and congestion, confined almost entirely to the pars anterior and disorganising it (Fig. 3). There was also an excessive number of the chromophobe type of cell, so that the condition may be described as a hæmorrhagic chromophobe adenoma of the anterior part. This was associated with a general condition of the animals, which is generally taken to be hypopituitarism. In man also chromophobe adenomas are known to produce a state of hypopituitarism.³ The condition produced by us experimentally resembles in many respects the syndrome of a disease in man known as Simmonds' disease. This disease, which is found more frequently in women than in men and is said often to follow parturition,⁴ is associated with an extensive destruction of the anterior part of the pituitary.

According to the prevailing conception, the pituitary presides over the whole endocrine apparatus, and it is therefore probable that the changes observed by us in the other endocrine organs are secondary to the changes in the pituitary. But if the pituitary presides, its position is not that of a dictator but rather of a *primus inter pares*. For as our experiments show, it is itself susceptible to hormonal influences coming from another part of the endocrine apparatus. Since in these experiments the changes in the pituitary and the development of malignancy in the mammary gland are both produced by œstrin it is reasonable to suspect that the two may be ætiologically related. Further investigations are necessary to determine how the chain of events is linked together.

As this paper is a preliminary communication we have restricted ourselves to statements on new and outstanding changes which we believe to have established on a sufficiently large material, and we have refrained from mentioning observations which will have to be repeated and checked by further experiments. Since œstrin preparations are now being used extensively in gynæcological practice it may be

well to point out that the carcinogenic changes here described were produced by the administration of œstrin prolonged over a period representing a considerable fraction of the normal span of life of a mouse and corresponding in man to a period of from 7 to 10 years, while the therapeutic administration of œstrin preparations in man is, in skilled hands, limited to short periods of a few weeks or months. The development of mammary cancer described in this paper should not, therefore, be used as an argument against the therapeutic application of œstrin preparations. The discovery that the sphere of action of œstrin preparations extends beyond the generative organs and embraces the whole endocrine apparatus is likely to enhance greatly their therapeutic importance.

KÜMMELL'S DISEASE

By JOHN P. HOSFORD, M.S. Lond., F.R.C.S. Eng.

ASSISTANT DIRECTOR, SURGICAL PROFESSIONAL UNIT,
ST. BARTHOLOMEW'S HOSPITAL

(WITH ILLUSTRATION ON PLATE)

In 1894 Kümmell gave an account of six cases of a condition of the spine which he said had not previously been described. Actually Verneuil had described it in 1892. Since that date Kümmell has published several more papers on the subject and other writers have reported many cases. The condition has come to be known as Kümmell's disease (Kümmellsche Krankheit).

Kümmell divided the course into three stages, but Cardis, Walker, and Olver have described five stages. Briefly they are:—

1. *History of an injury.*—This may be quite slight, or severe enough to keep the patient in bed. The injury is not usually directly to the spine but affects it indirectly by sudden forced flexion, as, for example, a doubling-up injury when a mine shaft collapses on a man, or a fall on to the buttocks from a height causes a sudden jar to the spine.

2. *Post-traumatic period.*—This also is very variable. There may be no symptoms. On the other hand, there may be local pain in the back and rarely even paraplegia is seen.

3. *Latent period.*—During this stage there are no symptoms. Any pain or paraplegia has disappeared

EXPLANATION OF PLATE

MR. RYCROFT

FIG. VII. (CASE 1).—Before operation (left) the right cornea is completely grey and opaque. The graft (right) is not bevelled and its appearance should be compared with that of the bevelled graft shown in Fig. VIII.

FIG. VIII. (CASE 3).—The condition of the only eye. The vacant staring appearance contrasts with that after operation shown on the right.

MR. MONTEITH

FIG. I.—Fracture: paratrochanteric and of shaft and lesser trochanter.

FIG. II.—Protraction, abduction, and flexion: detachment of lesser trochanter.

FIG. III.—Metal stay incorporated, maintaining abduction and flexion without protraction: reposition of lesser trochanter.

FIG. IV.—State of femur seven months after injury.

MR. HOSFORD

Compression fracture of ninth dorsal vertebra in case, clinically and radiographically resembling Kümmell's disease.

MR. COSBIE ROSS

FIG. I. (CASE 1).—The narrower tube is the one draining the common bile-duct. The radiogram shows the lipiodol, part of which is filling the duct, and the remaining part in the duodenum.

FIG. II. (CASE 2).—The common duct is outlined by a thin column of lipiodol, part of which has passed on into the duodenum. The two translucent smaller areas are due to air bubbles which entered with the lipiodol.

FIG. III. (CASE 3).—This reveals the second part of the duodenum clearly outlined by lipiodol, while the common duct is barely seen.

FIG. IV. (CASE 4).—In this case the whole biliary tract is outlined, there is dilatation of the common duct but free entrance to the duodenum.

FIG. V. (CASE 5).—This again reveals free passage of the lipiodol into the duodenum.

It is very variable in length and may be anything from a few days to months or even years.

4. *Onset of fresh symptoms.*—These are chiefly pain in the back and a sharp kyphosis at the site of the affected vertebral body which in a skiagram is seen to have collapsed.

5. The last stage depends on the institution of proper treatment or otherwise. If treatment is neglected there is complete collapse of the affected vertebra, whereas if satisfactory treatment is carried out any collapse of the bone is prevented and there is a resolution of the pathological change.

A number of theories have been advanced from time to time to account for this post-traumatic collapse of a vertebra. It will suffice to mention a few of these.

Kümmell originally believed it to be a "rarefying osteitis" of inflammatory origin following a disturbance of nutrition of the bone. Later he took the view that there was always some damage to the bone. In two further papers in 1928 he refers to Schmörl's work on prolapse of the nucleus pulposus of the intervertebral disc into the body of the vertebra, as having some bearing on Kümmell's disease.

Ieule believed that the changes in the bone were due to vasomotor disturbances brought on by trauma. Mikulicz held that trauma caused intra- and extradural hæmatomata which, by infiltrating nerve-roots and ganglia, brought on trophic changes which caused a softening of the bone. Ludloff found rupture of vessels of the lumbar segments and considered that the subsequent changes in the bone were due to nutritional impairment.

In the last few years post-traumatic atrophy has been widely discussed, and it has been suggested that Kümmell's disease is an example of it. Watson Jones and Roberts state, "If it be accepted that Kümmell's disease of the spine . . . can occur in the absence of any fracture, it is to the hyperæmic decalcification of contusion of the vertebrae that the condition must be ascribed." King goes further and seems to believe that Kümmell's disease can occur in the absence of any fracture and is of the nature of a post-traumatic hyperæmic rarefaction.

THE RADIOGRAPHIC DIAGNOSIS

It must be obvious that in order to establish a diagnosis of Kümmell's disease in the case of a patient with kyphosis there must be available one skiagram taken soon after the injury showing an apparently normal vertebra and another at a later date showing collapse of the vertebra. It is essential to have a lateral view of the vertebra, anterior and posterior views being of little value in detection of any abnormality in the body of a vertebra. Also the skiagram must be good enough not only to show the outline of the body but also to show, at least to some extent, the internal architecture of the bone.

Without such a skiagram it is quite impossible to say whether at the time of the original injury to the spine there was a fissured fracture of a vertebral body without displacement or whether no actual damage was done to the bone. The latter must be the case in order to establish the diagnosis of Kümmell's disease.

A search for a case of Kümmell's disease in which there is a satisfactory lateral skiagram immediately after the accident is not very fruitful. Kümmell's first papers were published before the days of X rays. In some of his later papers there are reproduced two skiagrams, one showing an antero-posterior view of a man's spine taken some time after the accident, and a later view showing some collapse of a vertebra.

The first antero-posterior view, however, although it is a good skiagram, is quite useless as negating any injury to the body. Of the comparatively few cases he quotes, this is the only one of which any skiagrams are produced.

In Schultz's extensive review of the condition with reports of 21 cases no skiagrams are reproduced.

Baker in the eight cases he quoted did not see any skiagrams taken immediately after the accident nor was he able to get reports on them.

Blaine described ten cases but none of them were radiographed in the early stages.

Cardis, Walker, and Olver, in 1928, quoted 14 cases in their excellent paper on Kümmell's disease, but in only one was any reference made to an early skiagram before collapse of a vertebra, and this was not reproduced.

In 1931 Rigler reported one case, that of a woman aged 55, who had a severe injury and was in bed for seven weeks with pain and weakness in the back. About a fortnight after getting up a skiagram showed no apparent abnormalities of the seventh or ninth dorsal vertebrae, but nine months later a second skiagram showed that they were compressed. This may have been a case of Kümmell's disease without any initial fracture, but during seven weeks in bed the vertebrae had time to begin to consolidate if there was a fracture, and two weeks out of bed is little time for compression to begin to show itself distinctly.

King reported six cases. One of these is an important case because there was the opportunity for an autopsy and a very detailed examination was carried out. It was the case of a woman of 57 who had a "severe fall," and later developed a kyphosis and paraplegia. It is most unfortunate that no skiagrams were obtained at the time of the fall. No early skiagrams are reproduced in any of his six cases.

From a careful examination of the literature I have been unable to find a case of Kümmell's disease in which a good lateral skiagram taken after the initial injury shows a normal vertebra. The following case may be quoted :—

In 1929 a labourer, aged 55, fell twenty feet off a ladder and was admitted to St. Bartholomew's Hospital. He had sustained a laceration of his scalp and a fractured clavicle, and complained of pain in the lower dorsal region. No deformity was present. Skiagrams were taken twice but showed no abnormality. He walked out of hospital three weeks later. After a further week a slight angular deformity was visible in the lower dorsal region and a skiagram showed a compression fracture of the ninth dorsal vertebra (Figure on Plate).

This is not quoted as a case of Kümmell's disease but as one of a fracture of the body of the vertebra which was missed at the first examination; it is, however, an exact parallel to many cases reported as Kümmell's disease in that (1) skiagrams taken immediately after the accident showed no deformity (but they were not really satisfactory views); (2) there was a latent period; and (3) compression and deformity were seen at a later date. One cannot but believe, however, that this is anything other than a case of compression fracture of a vertebra which was not recognised by the clinician or the radiologist; and there seems no reason to invoke any other pathology than that of fracture, nor to give it any other name.

DOES THE DISEASE EXIST ?

In 1928 Cardis, Walker, and Olver described Kümmell's disease as still struggling for recognition. There surely must be some doubt about the real existence of any condition which, over thirty years after its first description, is not fully recognised. There seems no real reason to believe that Kümmell's disease is anything other than a fracture of a

vertebral body. At the time of the original injury there are presumably one or usually more fissures through the bone. There may be little or no compression at the time: even if there is some compression it is likely to disappear when the patient lies flat in bed and so might not easily be recognised in a skiagram even if the latter were obtained. If at this stage the true state of affairs is recognised and a fracture of the body of a vertebra is diagnosed, appropriate treatment is carried out, the spine being immobilised in the fully extended position; no compression of bone is allowed to take place and the bone consolidates in its normal shape and position and the case is looked upon as a satisfactory result of a fracture of a vertebral body. On the other hand if the possibility of a fracture of a vertebra is overlooked for any reason and a kyphosis appears at a later date, no proper treatment having been carried out, it has been customary to refer to it as Kummell's disease, and to discuss a variety of pathological changes which may have brought it about.

If we look in other parts of the body for the same changes following a fracture which has been overlooked and not properly immobilised, we see similar absorption and loss of bone substance. Typical situations where these changes are seen when efficient fixation has not been employed are in fractures of the neck of the femur, and in the common fracture of the carpal scaphoid. In this connexion it is of particular interest to find that King, a strong advocate of the theory that Kummell's disease is due to a post-traumatic hyperæmic rarefaction, says: "The usual finding then even in the cases in which there is fracture, is an active hyperæmia."

It seems inconsistent and confusing therefore to make an exception of the vertebral bodies and give a special name to an overlooked fracture in this situation when no such deception is carried out in the case of other bones. Kummell must be given every credit for his observations and for drawing attention to the delayed collapse of a vertebra after an injury rather than for his explanation of this delayed collapse.

Thus it would seem to be advisable to teach not that there is a condition known as Kummell's disease of somewhat obscure pathology but that: (1) Compression fractures of the bodies of the vertebrae are easily overlooked owing to their relatively mild symptoms and absence of signs. (2) In all cases of pain in the spine following an injury skiagrams of the vertebrae should be taken and if the lateral view is not clear it should be repeated. (3) If the skiagrams show no fracture and the pain persists when the patient has got up, another lateral skiagram should be taken and the closest clinical observation kept for the onset of any kyphosis. (4) Treatment in an ambulatory plaster jacket should be instituted at the earliest sign of any injury to a vertebral body.

THE USE OF
 LIPIODOL IN SURGERY OF THE
 BILIARY PASSAGES

By J. COSBIE ROSS, Ch.M. Liverp., F.R.C.S. Eng.
 HONORARY ASSISTANT SURGEON, LIVERPOOL ROYAL INFIRMARY;
 SURGEON, SMITHDOWN-ROAD MUNICIPAL HOSPITAL;
 DEMONSTRATOR OF OPERATIVE SURGERY,
 UNIVERSITY OF LIVERPOOL

(WITH ILLUSTRATIONS ON PLATE)

WHILE the use of lipiodol in the post-operative management of cases involving the biliary ducts is by no means new, general application of the method is unusual. Gabriel¹ in 1930 described a case where a biliary fistula was demonstrated by X rays after the injection of lipiodol, and Ginsburg and Benjamin² reported a series of cases in the same year.

During the course of operations on the gall-bladder it is sometimes a surgical necessity to explore the common bile-duct when the latter is dilated and when the presence of stones is suspected. Often it is possible to suture the common bile-duct with safety after incision and exploration; in these cases a drainage-tube is desirable, secured to the suture line by a single stitch. Usually the suture line remains watertight, and no bile is discharged through the precautionary tube. There are occasions, however, when the local pathology of the ducts demands drainage by a catheter, especially where numerous stones have been removed from the ducts and where infection of the latter is present.

In my own series, consisting of 110 operations for cholecystitis, the common bile-duct was explored 27 times with 4 post-operative deaths. The proportion of cases with stones in the gall-bladder or ducts represented 80 per cent., whereas in a previous investigation of 153 cases, 87 per cent. had the combined pathology of inflammation and stones.³ Out of the 27 explorations of the common bile-duct, stones were found in the ducts and removed in 16 instances (see Table).

Operations on the biliary tract (over 80 per cent. had stones in addition to cholecystitis)	110
Cholecystectomy	82

(d) Generalised inflammatory sclerosis of the ducts	1
Stones present in biliary ducts	16
Number of lipiodol injections carried out	14

INDICATIONS

In 3 of the 27 cases in which exploration of the ducts was necessary, it was carried out through the stump of the cystic duct. In another case a generalised inflammatory sclerosis of the ducts was found a year after cholecystectomy had been performed; in this case no drainage was instituted. In 6 cases the bile-duct was sutured after exploration, but in 17 a catheter was stitched into the duct for various reasons, usually where numerous stones had been removed or where infection was present.

In a few of the latter cases it was not certain at the time of the operation whether the ampulla of Vater was patent, owing to the necessity of concluding the operation rapidly in view of the poor condition

or advanced age of the patient. In an elderly patient with jaundice due to a stone in the common bile-duct the operation may be necessarily a hurried and inadequate one, and the time required for complete exploration of the ampulla not available without undue risk. To quote the late Mr. Frank Jeans, "better a live problem than a dead certainty." Moreover, even with available time to pass a bougie, or to pass a rubber catheter and subsequently to pump saline through it into the duodenum, it is possible to miss a small stone, especially where there is much thickening in the vicinity of the ampulla, and where chronic pancreatitis is a prominent complication. Kehr admitted missing stones in the biliary ducts in 2.5 per cent. of 1105 operations, and Deaver reported that second operations constituted 4 per cent. of 1189 explorations of the biliary passages.⁴ It is in the post-operative management of such cases as these that this method appears to be of value. Lipiodol is especially useful in what might well be called "second-hand" operations on the biliary tract. These cases are notoriously dangerous and difficult, and four examples are included among the present series. In connexion with these second-hand cases, the incision of choice appears to me to be a Kocher when a paramedian has been used on the previous occasion. A Kocher incision ensures that the operative field lies between the adhesions caused by the previous operation and the liver, and frequently the general peritoneal cavity is completely excluded, a useful feature when biliary drainage is contemplated.

Many tests have been used at various times for determining the patency of the common bile-duct. Among the better known tests are the following:—

1. The examination of the stools for bile-pigment.
2. The introduction of an Einhorn tube into the duodenum and the injection through the tube of magnesium sulphate solution. No bile is obtained through the tube when the common bile-duct is completely blocked.
3. The disappearance of jaundice.
4. The van den Bergh test.
5. If a T-tube has been introduced into the common bile-duct for drainage purposes, jaundice will occur when the outer extremity of the tube is clamped if there is not free entry of bile into the duodenum.

The most commonly used test is that mentioned first, but the following obvious fallacy suggests itself. If the faeces are normal in colour, bile is entering the duodenum without hitch; but where it is necessary to drain the common bile-duct for several days, all the bile may be discharged through the drainage-tube in spite of the fact that the ampulla of Vater is patent. Thus, this time-honoured test is not of great value where drainage of the common bile-duct is taking place. In fact, none of these tests are reliable criteria as there may be a partial suppression of bile giving light-coloured stools with a patent duct.

Finally, injection of lipiodol will not only indicate whether the block is partial or complete, but will demonstrate the site, and will exclude that due to spasm of the muscle of Oddi. If the lipiodol is held up in the common hepatic duct or supraduodenal part of the common duct, it is suggested that the usual cause is fibrous stricture, while ampullary blockage is commonly due to a stone if muscular spasm is excluded. Although the very definite advantages of the T-tube must be freely admitted, I have never succeeded in overcoming a prejudice due to the split in the common duct necessarily produced when finally withdrawing the tube, and due to the bulky T junction. This may or may not predispose to stricture formation, but I feel safer

with a soft rubber catheter which can be introduced through a small incision in the duct, can be removed without causing any further damage, and has in my experience provided excellent drainage. Further, although in previous papers the injection of lipiodol has been carried out through a T-tube, equally good results can be obtained through a soft catheter.

Although it is the usual custom in this country, and my own practice, to remove this catheter ten days to two weeks after the operation, Overholt⁵ is strongly of opinion that it should not be removed before the patency of the biliary tract has been demonstrated by lipiodol. His statement that a tube in situ is easier to deal with than a biliary fistula appears at first sight to require some consideration; but a recent case has convinced me that a tube is certainly safer than a fistula. In this case drainage of the common duct had been carried out by another surgeon 14 days previously. On the 10th day the tube was removed, and on the 11th the fistula superficially closed, and pain and discomfort were experienced in the right upper quadrant of the abdomen. On the 14th day general "bile" peritonitis suddenly supervened, and at operation large quantities of bile were evacuated from the peritoneal cavity. What had happened was that bile had collected in the region of Morison's pouch, owing to ampullary block and to premature closing of the biliary fistula.

A further argument in support of Overholt's view is furnished by Pribram's method (described below) for the solution of ampullary stones by ether.

TECHNIQUE OF INJECTION

About ten days after the operation, 10–20 c.cm. of warmed lipiodol are slowly injected into the tube draining the common bile-duct. Before doing so, any bile in the tube is aspirated, and care is taken to use no force in injecting the opaque liquid. Immediate radiography will show the lipiodol in the duodenum if the duct is patent; it is remarkable with what rapidity the lipiodol passes into the duodenum, and it is almost impossible to outline the ducts in such a case. For this reason lipiodol cannot be relied upon to demonstrate a residual stone which is not causing obstruction. The non-opaque stone may be outlined by adsorbed lipiodol, but the latter passes on so quickly into the duodenum that no indication may be given.

The radiogram, however, may reveal the lipiodol filling the common bile and common hepatic ducts and stopping short at the ampulla. This hold-up may be due to spasm of the ampullary sphincter or to an impacted stone. In the former case, a second radiogram taken three-quarters of an hour after the hypodermic administration of atropine may reveal that the lipiodol has passed into the duodenum. If the opaque fluid has entered the duodenum either before or after the administration of atropine, the tube draining the common bile-duct may be withdrawn with safety on the tenth day after the operation with the confident expectation that recovery will take place without either the supervention of jaundice or of persistent biliary fistula. If, on the other hand, the lipiodol is persistently held up at the ampulla, a stone in that situation is very probable.

VARIOUS CONSIDERATIONS

The sphincter of Oddi.—There is considerable divergence of opinion as to the effectiveness of this sphincter. Pribram⁶ states with conviction that sphincteric spasm occurs frequently and may produce characteristic symptoms. This view is supported by Kretchner,⁷ who reproduces an interesting radio-

gram in which the lipiodol is shown filling the common bile and hepatic ducts and also outlining the lower end of the duct of Wirsung. This observation seems to throw some light on the pathology of acute hæmorrhagic pancreatitis. On the other hand, as previously mentioned, all observers have commented on the rapidity with which the opaque fluid enters the duodenum in the great majority of cases.

Biliary dyssynergia or spastic dyskinesia.—While this condition of abnormal tonus of the ampullary sphincter may be deduced by the use of the duodenal tube, it can only be positively demonstrated by injection of lipiodol. There is steadily increasing clinical and physiological evidence not only of the effectiveness of the sphincter but also of the occasional presence of biliary dyssynergia.

Reference may be made especially to the recent work of Russell Best and Frederick Hicken.⁸ These authors compare lesions of the ampullary sphincter with cardiospasm, pylorospasm, &c., and bring forward much radiological evidence that biliary dyssynergia may produce a definite mechanical block to the passage of bile into the duodenum. It is further claimed that the subsequent dilatation of the biliary ducts may produce attacks of biliary colic, and that the condition may be independent of cholangitis, the presence of stones, strictures, duodenitis, or pancreatitis. This view offers a reasonable explanation of the occurrence of biliary colic and of the so-called "hepatic neuralgia," and accounts for the persistence of gall-bladder symptoms in some few individuals after removal of the gall-bladder. These post-operative symptoms have usually been attributed in the past to congestion or infection of the ducts, or to the elusive "missed stone." When a definite diagnosis of biliary dyssynergia has been made by injection of lipiodol, the post-operative régime should include substances which relax the choledochal sphincter such as atropine, magnesium sulphate, or fats. It is interesting to contemplate the possibility of biliary dyssynergia, occurring as a primary condition, causing stagnation of bile and predisposing to the precipitation of stones.

Additional applications.—The method, may also be applied where cholecystostomy has been performed, the opaque fluid filling the gall-bladder and the ducts provided the cystic duct is patent. Similarly, where the gall-bladder has been drained in a case of acute pancreatitis it is helpful as well as instructive to demonstrate or exclude sphincteric spasm.

Possible dangers of the method.—Tenney and Patter-son⁹ have recorded a case where pyrexia, jaundice, and abdominal pain were produced by the injection of bismuth paste under pressure into a biliary fistula. The explanation here seems to be the simple one of a thick paste blocking both fistulous tract and common bile-duct, especially as the symptoms subsided subsequently. It is obvious that bismuth paste is highly unsuitable for this diagnostic measure.

Mallet-Guy, Beaupère, and Armanet,¹⁰ who record the onset of similar symptoms some hours after injection of lipiodol, are inclined to blame the viscosity of lipiodol blocking the common bile-duct and pancreatic ducts, and the production of "pancreatic œdema." In the latter case, however, there were several anomalous features. For instance, the jaundice was of painless onset following a course of neosalvarsan, and no stone or obstruction of the ducts was found at operation. Moreover, two further injections of lipiodol were given after the original 20 c.cm. in an attempt to outline the biliary tract.

In my opinion it is a great mistake to aim at outlining the ducts. If there is no obstruction the opaque solution passes into the duodenum with great rapidity, and little more than a minute residue is to be seen in the ducts. For this reason it is difficult to demonstrate with certainty a stone not producing a complete block. Occasionally, such a non-opaque stone is shown in the radiogram as a clear area outlined by lipiodol. Again, it is difficult to assess the value of outlining the biliary tract in cases of obstruction. It is sufficient for practical purposes to test the patency or otherwise of the biliary system, and this appears to be a safe procedure. I have carried out the diagnostic injection of lipiodol in 14 cases without the production of symptoms or other effects in any instance.

Ether solution of stones impacted at the ampulla.—When a stone has been demonstrated at the ampulla by lipiodol, Pribram advises the daily injection of a few cubic centimetres of ether into the tube draining the common duct for several days. He has shown that ether disintegrates certain gall-stones by dissolving the cholesterol nuclei, thus reducing the stones to a pultaceous mass. The latter passes readily through the ampulla into the duodenum. The application of this method to the treatment of biliary fistulæ is obvious. A fine rubber tube is introduced through the fistula down to the obstruction, and the subsequent daily injections of ether may obviate a difficult and dangerous operation in cases where the obstructing agent is a stone.

I have not had an opportunity of using ether as a solvent of gall-stones, for in the cases recorded below the lipiodol passed into the duodenum either before or after the administration of atropine; but from Pribram's recorded cases this method seems to deserve extended trial.

CASE REPORTS

CASE 1.—This was a woman, aged 67, who had had an operation for cholecystectomy performed some years previously. Operation was necessitated by repeated attacks of severe biliary colic associated with jaundice. The jaundice varied in intensity but never completely cleared. Her general condition was poor, and there was some jaundice at the time of operation. In view of the two latter facts, and of her age, the operation was necessarily a hurried one performed under gas-oxygen anaesthesia. Many adhesions had to be separated before the common bile-duct could be exposed and incised. Several faceted stones were removed from the common bile-duct, but her condition did not permit of more than a hasty palpation of the ampulla of Vater. A catheter was inserted into the common bile-duct and drained bile for nine days after the operation. Lipiodol (10 c.cm.) passed easily through the common bile-duct into the duodenum (Fig. 1. on Plate), so the tube was removed on the ninth day. She was discharged from hospital three weeks after the operation and has not had either jaundice or biliary colic from that date.

CASE 2.—This was a male, aged 20, who was admitted to hospital with severe biliary colic which settled down, but was succeeded by jaundice. At the operation a strawberry gall-bladder with thick pink walls was removed and the common bile-duct exposed. When the common bile-duct was opened a collection of "bile mud" was evacuated. The subsequent bile was normal in appearance and consistency. The ducts appeared to be sub-acute inflammation, and a row of elastic glands were found in the right edge of the gastrohepatic omentum immediately behind the common bile-duct. These glands appeared to be secondary to the strawberry gall-bladder, and subsequent microscopic examination confirmed that their origin was inflammatory. Several of the larger glands were excised in order to avoid extrinsic pressure on the duct. It was found possible to pass a 7/10 bougie through the common bile-duct into the duodenum with

ease. A catheter was inserted into the common bile-duct and the operation concluded. A few days later radiography revealed the lipiodol in the duodenum (Fig. II). This patient was discharged from hospital three weeks after operation, his jaundice having completely cleared and his wound healed.

CASE 3.—This was a female, aged 48, who had had two previous operations elsewhere, one of which consisted of cholecystectomy, incision of the common bile-duct, and removal of stones from the hepatic and common bile-ducts. A subsequent operation was performed for incisional hernia. She was admitted to hospital suffering from severe biliary colic, and a history of two recent mild attacks of jaundice. The abdomen was opened through a Kocher's incision, and the common hepatic duct exposed after a prolonged and arduous separation of adhesions. The common bile-duct and the duodenum were welded together by dense inflammatory adhesions that defied separation. The common hepatic duct was opened and several stones removed from it and the common bile-duct. A probe passed into the duodenum, but the probe could not be identified in the dense inflammatory mass just above the first part of the duodenum. A drainage-tube was inserted into the common hepatic duct and the operation concluded. Although it was possible to pass the probe into the duodenum, it was not possible to exclude completely stone or stones at the lower end of the common bile-duct, so that it was very satisfactory, a few days later, to obtain a clear radiographic picture of the common bile-duct and to see that the lipiodol had passed without hitch into the duodenum (Fig. III). The patient subsequently had an uninterrupted convalescence.

CASE 4.—This was a female, aged 62, who had had two previous operations—one for cholecystectomy and another for a perforated gastric ulcer. Her general condition was poor and there was definite evidence of myocardial degeneration. Operation was necessitated by repeated attacks of severe pain. The abdomen was opened through a Kocher incision and the common bile-duct exposed. The adhesions were especially dense as the previous perforated gastric ulcer added its contribution of adhesions to those due to the cholecystectomy. The common bile-duct was opened, stones removed, and a catheter inserted into the duct which was approximately one inch in diameter. A 9/12 bougie passed easily into the duodenum; the operation was concluded. After the operation her condition was never satisfactory, but the patency of the common bile-duct and ampulla of Vater were demonstrated by the rapid passage of lipiodol into the duodenum (Fig. IV.). Unfortunately, however, her condition became steadily worse, and death occurred one month after the operation. A post-mortem was not obtainable, but all clinical evidence went to suggest the cause of death to be myocardial failure rather than any biliary upset. There was no suppression of bile at any stage of her illness.

CASE 5.—This woman, aged 48, came into hospital with a history of three attacks of severe abdominal pain and vomiting, said to have been associated with the doubtful appearance of jaundice on one occasion. One of these attacks had occurred a few days before her admission to hospital. When examined there was protective spasm and tenderness over the whole of the upper abdomen, especially over the gall-bladder. Radiography of the latter revealed two opaque gall-stones in the gall-bladder, which did not fill or excrete dye. The gall-bladder was exposed by a Kocher's incision, and chronic cholecystitis and cholelithiasis were found, in conjunction with subacute pancreatitis. The pancreas was swollen, oedematous, and inflamed, and there were small areas of recent fat necrosis. Obviously, the attack from which she had suffered several days before admission to hospital had been that of an acute or subacute pancreatitis. The gall-bladder was opened, the stones removed, and a cholecystostomy performed. It was decided not to drain the pancreas as there did not appear to be any indication to do so, especially as the condition was obviously subsiding.

This patient's convalescence was smooth, and a radiogram of a subsequent injection of lipiodol through the tube draining the gall-bladder revealed the opaque fluid in the duodenum (Fig. V.).

SUMMARY AND CONCLUSIONS

1. Operations on the biliary passages often present difficulties, especially where the post-operative management is complicated by doubts as to the patency of the ducts. 2. The usual clinical tests for determining the patency of the ducts, especially the presence of bile-pigment in the faeces, are often fallacious. 3. The injection of lipiodol into the common bile-duct presents no difficulty, is not dangerous in itself, and yields valuable information. 4. The lipiodol method determines the prognosis with accuracy. Further, it indicates the advisability or otherwise of removal of the tube draining the common bile-duct, and the possible application of additional measures. 5. The condition of biliary dyssynergia affords a reasonable explanation for post-operative symptoms in patients where cholecystectomy has been carried out. The diagnosis of this condition can only be made positively by means of the lipiodol injection, and when such a diagnosis has been made, post-operative treatment should be directed towards promoting relaxation of the ampullary sphincter. 6. Some typical examples are described in which the lipiodol method has proved of value.

I am indebted to Dr. P. H. Whitaker whose welcome help has been of the greatest assistance to me from the radiological aspect.

Clinical and Laboratory Notes

BEDSIDE RADIOGRAPHY FOR A FRACTURE

BY W. B. R. MONTEITH, M.A. Camb., F.R.C.S. Edin.

(WITH ILLUSTRATIONS ON PLATE)

AN agricultural labourer of 75 presented himself at my house recently suffering from a cold in the head incapacitating him from work. This was two years after he had fractured his femur and a few days after I had been reading about the need for fracture clinics in this country. It seems to me in retrospect that this man's sound functional recovery and ability to do full work illustrates first the value of detail in treatment, and secondly the value of radiography in bed without disturbance. These should be available whether the patient is treated at home, in hospital, or in a fracture clinic.

At the age of 73 this man fell heavily from a haycart. Shortly after admission to the Butterfield Hospital, Bourne, X ray examination (Fig. I. on Plate) showed a comminuted fracture of the left femur, involving shaft, neck, and both trochanters. By means of strapping along the length of thigh and leg traction was applied, with the leg rested in a Thomas splint and abducted and flexed at the hip-joint. A subsequent radiogram, taken without moving the patient, showed satisfactory abduction, protraction, and alignment, but with small trochanter displacement, due undoubtedly to pull by the psoas (Fig. II.). It then seemed best that the abduction and flexion should be maintained without further protraction.

A rigid iron frame was made to extend from lower ribs to calf, having riveted to it at right angles a half hoop to embrace thorax and cross strips at mid-thigh and calf; and having the longitudinal strip bent, at the level of the hip-joint, outwards through 30° to maintain abduction and upward through 40° to maintain flexion. This was incorporated in a plaster-of-Paris case extending from the lower ribs and enclosing the foot on the left side, and to the knee on the right. X ray examination then showed satisfactory disposition of the fragments (Fig. III.). After two months the left knee was liberated, the metal support having been sawn through at that level, and the plaster case removed from knee downwards. After three months weight bearing was permitted while still wearing the plaster case. Four months after the accident the patient was discharged from hospital wearing a walking calliper. This he discarded (contrary to instructions) after a few weeks, for he complained that it interfered with digging! Fig. IV. shows the state of affairs seven months after the injury.

It is now two years since the accident, and for more than twelve months he has been doing full work including potato digging. There is a good range of movement at the hip, though some limitation of abduction, and no measurable shortening. The man himself admits no disability.

The successful result emphasises once more the fact that stereotyped methods of treatment are inadvisable. On the positive side it points to the extreme value of intercurrent radiography, without disturbance of limb or patient, as a means of making the treatment suit the patient.

Bourne, Lincs.

A METHOD OF TYING IN A CATHETER

By G. B. DAVIS, M.R.C.S. Eng.

HOUSE SURGEON TO THE UROLOGICAL DEPARTMENT AT KING'S COLLEGE HOSPITAL, LONDON

MANY methods have been devised for keeping a catheter securely in place, ranging from simple but primitive devices to elaborate "machines." Probably the method most commonly used now, in hospital and private practice, is the system of tapes tied to the catheter, the four ends being held to the penis by an encircling band of strapping. Even this has disadvantages. (1) It takes time to put on neatly. One is apt to get "tied up" with the seemingly innumerable ends of tapes and strapping, and often when it is completed all the tapes

are not equally taut. (2) The tapes, being close to the penis, become very dirty from urine and pus tracking round the catheter. (3) With the slight and unavoidable tension on the catheter, the tapes become taut, and cut into the penis as they converge on the catheter. This occurs especially as they cross the corona, and I have often seen ulcers where tapes, hardened by dried urine and pus, have cut into the glans. This is, perhaps, the greatest objection to the method. (4) If the catheter has to be changed, or removed temporarily (e.g., for cystoscopy), the whole apparatus must be removed and a fresh one applied.

These objections may appear trivial but in practice are very real. The appearance of things after a catheter has been kept tied in for a week in a patient with infected urine or urethritis is enough to make one most dissatisfied with the tape method.

The following method aims at meeting these dis-

advantages, and, if not entirely overcoming them, at least mitigating them. Its essential feature is the use of something more rigid than tapes. A material which was soft, stiff, and at the same time pliable seemed indicated, and for this purpose pipe-cleaners have proved the ideal thing. They cost 1d. per packet of 12, and four are necessary for each case, the "extra thick" variety being the best.

After the catheter has been passed, four pipe-cleaners are strapped with 1 inch Elastoplast strapping round the circumference of the penis, as near the base as possible. The four ends are then brought to the catheter and fixed there with a small strip of elastoplast, in such a way that each pipe-cleaner has a definite bow, and stands well away from the glans penis. The ends at the base of the penis are then bent back or cut off. It is important to apply the band of strapping loosely round the penis to avoid constriction and œdema, and to press it well on to the skin. The whole procedure takes under a minute, with practice, and has proved quite satisfactory.

Unlike the tapes, pipe-cleaners have the necessary rigidity to "stand away" from the penis and not press on the corona. Because they can be made to stand away, too, they are not soiled so soon by urine or pus. Being soft, they do not cut into the skin, and are quite comfortable to the patient. If the catheter has to be removed temporarily, the strapping holding the ends on the catheter is removed, leaving the pipe-cleaners in place, ready to be strapped again to the new catheter. The method is essentially simple, clean, and very easy to apply. By his kind permission, it has been used on the last 30 cases under the care of Mr. John Everidge.

AN UNUSUAL CAUSE OF INTERNAL HÆMORRHAGE

By EMLYN E. LEWIS, F.R.C.S. Eng.

RESIDENT SURGICAL OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM

EARLY in August, 1935, a man 77 years of age was admitted to the Queen's Hospital having collapsed in the street. He was suspected of having a perforated ulcer. He had been unwell for a few days, having shortness of breath. There was no indigestion. The collapse was ushered in by giddiness and by slight upper abdominal pain which by the time of examination had become severe and generalised. His pulse was rapid and thready, his temperature subnormal, and his skin cold and clammy. He was tender and rigid over the whole abdomen but particularly in the epigastrium; there was no diminution of liver dullness, and he had much pain in the right shoulder.

A diagnosis of mesenteric thrombosis was made, morphia gr. $\frac{1}{4}$ was given, and rectal saline administered. The patient's condition improved and in two hours the abdomen was opened under gas-and-oxygen anaesthesia. The peritoneal cavity contained a great quantity of blood. The spleen was intact, and the stomach was delivered with abnormal ease owing to the lesser omentum having been torn away from the lesser curvature. The torn omentum was widely infiltrated with blood-clot and expanded to a thickness of about 2 inches. No actual bleeding-point could be seen, and there was no evidence of fresh hæmorrhage. The man's condition being grave,

ROYAL SOCIETY OF MEDICINE

SECTION OF EPIDEMIOLOGY

AT a meeting of this section on Jan. 24th, with Surgeon-Captain S. F. DUDLEY, the president, in the chair, a discussion took place on the

Use and Abuse of the Swab in Combating Diphtheria

Dr. H. J. PARISH, of the Wellcome Research Laboratories, Beckenham, began by saying that if immunisation were universal and timely the subject would be unimportant, but that there was still much diversity of opinion and practice. The responsibility for the diagnosis of diphtheria rested entirely with the clinician. In typical cases the swab should have only a confirmatory value, but where, clinically, the presumption was against diphtheria, it might help him to decide. Good technique was essential at the bedside as well as in the laboratory, and swab-taking should not be delegated to a student or nurse. An antiseptic gargle should not have been used for some time before using the swab, and with only a small nidus of infection care must be taken to rub the actual lesion and to avoid contamination with saliva. In a difficult case the bacteriologist should be given adequate data, and he, in turn, should issue his report without delay. He felt that antitoxin should be given whenever a swab was taken, as many lives were still being lost through failure to give serum early enough. The swab should be of greater value to the clinician and the medical officer of health as an administrative measure rather than as a diagnostic aid. Doubtful cases should not be notified until there had been a report on the swab. If negative, another swab should be taken, and if this was also negative the patient could safely be nursed at home, even in the presence of Schick-positive children: Vincent's angina or streptococcal sore-throat might, however, require hospital care. Caiger and O'Brien had reported that in 41 per cent. of 529 patients admitted as cases of diphtheria, and Dr. E. H. R. Harries that in 33.6 per cent. of 2099, a revision of the diagnosis was necessary. An "observation certificate" for admission to hospital would save much expense and a rebuff to the practitioner when his diagnosis was revised, but for this the L.C.C. system of isolation cubicles would be essential. Sometimes the membrane of a transient true diphtheria in almost immune persons might clear before admission to hospital and these might soon be discharged. It was often necessary to swab contacts in order to acquire early information about the spread of infection, and it was important to swab the nose as well as the throat, for there might be a positive result in one when the other was negative.

(Continued from previous page)

after evacuation of the blood, the abdomen was hurriedly closed. It was suspected that the left gastric artery had ruptured, possibly through an aneurysm. Three days later the patient died, and post-mortem examination showed syphilitic aortitis, aneurysmal dilatation at the origin of the coeliac artery, and rupture into the lesser omentum of an aneurysm about an inch in length situated on the left gastric artery. Evarts Graham in his "General Surgery" (Chicago, 1931) records almost a similar case treated successfully by Green-Powers.

In many outbreaks the real menace was the profuse carrier, but though those with few bacilli probably helped greatly in natural mass immunisation, the sparse carrier of one day might be a profuse and dangerous one on the next. The introduction of tellurite media had materially increased the proportion of positive reports and this increased the clinician's responsibility in interpreting them. It was of supreme importance to make virulence tests in convalescents and carriers, for they often harboured non-virulent forms.

In research the swab was invaluable in discovering the presence of diphtheria in Schick-negative reactors, the invasiveness of *Corynebacterium diphtheriae gravis*, the carrier rate and the effect upon it of artificial immunisation, and the origin of natural antitoxin. Certain strains of the gravis type seemed to be more invasive than the strains met with a few years ago, and were responsible for most of the diphtheria in Schick-negative reactors. The degree of protection shown by a negative Schick test might occasionally be inadequate to prevent infection by virulent strains, and it should be the aim of the practitioner to confer as high a degree of protection as possible. With the increasing prevalence of the gravis organism in various parts of England not only had there been an increase in the number of cases reported in Schick-negative reactors, but sometimes also in the number of carriers associated with those cases. A high carrier rate in an immunised population might be due either to the immunisation itself or to a more virulent and invasive strain, but there was no doubt that mass immunisation very greatly reduced the incidence of diphtheria.

The clinician must realise that the newer knowledge had complicated the work of the bacteriologist and this might explain some of the negative reports in undoubted clinical diphtheria. Some modification of laboratory technique was therefore desirable, and Dr. Parish suggested as a method, first, the examination of the direct smear, chiefly to exclude Vincent's angina, and then inoculation of a Löffler slope and of McLeod's chocolate tellurite medium, on a plate or, more conveniently, in a McCartney's screw-capped bottle. This enabled a report to be made in from 24-48 hours, but was difficult to carry out in a small laboratory. It tended, however, to shorten the bacillus and make microscopical recognition difficult. A simpler alternative was to give a preliminary report in 18 hours from a Löffler slope and, later, a full report after a thick subculture of the easily made Horgon and Marshall's blood tellurite medium and after fermentation and virulent tests. The great advantage of the tellurite medium over Löffler's was that it produced an increase of 10-25 per cent. in the positive results. It also differentiated the Klebs bacillus from Hofmann's and the gravis type from the others, and by inhibiting the growth of other organisms it allowed the colonies to be picked out.

The swab saved precious time in making a diagnosis and though improvements in technique had added to the cost the full laboratory examination was not necessary in the ordinary typical case. He had himself found the serum-treated swab most valuable for accelerating the report. He had described it in a letter to THE LANCET,¹ and had shown that an accurate report could be made in two hours in 80 per cent. of clinical diphtheria and in four hours in

¹ THE LANCET, 1935, i., 400.

95 per cent., contrasting with 83 per cent. after the 18 hours necessary by Löffler's method. The value of the swab was highest in administration and research as it was desirable to have the largest possible number of isolations. It was often very difficult with persistent carriers to decide if they were to be released from strict isolation before they became bacteriologically negative. This step should only be taken after a thorough overhaul of the upper respiratory passages by a competent specialist. Swabbing must not be used as a primary or even chief means of diagnosis, for diphtheria was a disease, not a mere bacteriological finding. It was also necessary to differentiate clinical diphtheria from the mere presence of the bacilli in the throat. Finally, he urged that every hospital should have its own bacteriological laboratory and that there should be closer coöperation between clinician and bacteriologist, but the onus in regard to early diagnosis and treatment rested with the physician.

Dr. C. O. STALLYBRASS (Liverpool), from the point of view of public health and hospital administration, discussed the value of the swab for diagnosing diphtheria before admission, in the isolation hospital, and in carriers and "missed" cases. He assumed that the swab was supplementary to artificial immunisation. Of 200 consecutive cases admitted to Liverpool hospitals as diphtheria, the diagnosis was confirmed in 175: the average age was 10 years; the average delay in calling medical aid was 36 hours, with a further 16 hours before the first dose of antitoxin was given; the mortality was 8 per cent. Swabs were much more often taken from adults than from children, and the delay in sending for the doctor was much greater in fatal cases. The condition of the patient, judged by the dose of serum on admission, was much graver in the fatal cases and in those who had not been swabbed outside, whose mortality was little more than half the average of the series (4.8 as against 8). The main causes of death were a severe type of infection and failure to realise the gravity of the infection in young children (by doctors as well as by parents). He urged the use of the swab in all doubtful cases, especially in children under 7 years of age. He advocated the more frequent swabbing of the nose. If a positive swab taken outside the hospital was not necessarily proof of diphtheria, still less did a negative swab show its absence. Swabs negative to diphtheria often showed Vincent's angina and swabbing was invaluable in the differential diagnosis.

In hospital the use of the swab had been radically changed by the division into "gravis," "intermediate," and "mitis" types. In Liverpool a case notified as diphtheria was seen on admission by a resident medical officer. Clinical diphtheria was sent to a general ward, doubtful cases to a bed-isolation ward or cubicle. A swab was at once taken and a Schick test carried out, followed, if necessary, by a dose of serum after four to six hours. The cultures if positive were tested for virulence, and if negative a second culture was made a few days later. Of 145 gravis only 1 and of 116 intermediate strains only 4 were non-virulent, but of 121 mitis strains 43 were non-virulent. The proportion of the gravis type in various cities was found from the literature to vary greatly.

With an outbreak of diphtheria in a children's ward, a kind of standstill order should at once be put into operation. The children could be separated into four groups: (a) Schick-positive, swab-positive; these should be isolated and receive a dose of serum.

(b) Schick-negative, swab-positive; carriers who should be isolated until a virulence test was done. (c) Schick-positive, swab-negative; these should be left in the ward and immunised. (d) Schick-negative and swab-negative; these remained in the ward and needed no further treatment. After this the standstill order could be relaxed.

The abuse of the swab lay mainly in allowing the bacteriological finding to warp the judgment, causing clinical diphtheria to be called something else, or a mere carrier an active case. This, however, still left open the question of what constituted clinical diphtheria.

Dr. J. D. ROLLESTON agreed with both the previous speakers that there was a need for collaboration between physician and bacteriologist, and that the onus in diagnosis rested primarily on the physician. There was still too often delay in giving antitoxin or in sending patients to a fever hospital, because a swab had not been received or was negative. Malignant diphtheria might simulate quinsy or mumps, and a swab might be negative because the bacilli were too deep in the mucous membrane, and it only became positive when the membrane began to separate. The danger of a wrong diagnosis was shown when 58 per cent. died of 40 patients with malignant diphtheria which had been incised, compared with 3.4 per cent. of other cases of equal severity. The direct smear helped to diagnose Vincent's angina and to show the prevalence of other organisms, but it should be limited to acute faucial diphtheria. A negative swab might be due to the struggling of the child, to applying it too soon after meals, to a recent use of antiseptic, or to the inexperience of the examiner. In the skin, diphtheria might simulate eczema, herpes, different forms of suppuration, and in wounds, in a number of which diphtheritic paralysis resulted. Obstinate whitlows would disappear after a small dose of diphtheria antitoxin. He was sceptical of the practical value of terminal swabbing before the patient was discharged from hospital; a negative swab was no guarantee that the patient was free from infection, and the return rate was no higher in hospitals which had given up this practice. It had, however, a certain forensic value.

The CHAIRMAN referred to a psychological abuse of the swab. If there were no such measure as swabbing, the practitioner would probably treat all his cases of diphtheria with antitoxin at once. He had found a 25 per cent. increase in the number of positive swabs by examining at 48 hours as well as at 24 hours, and he thought terminal swabbing would be much more valuable if the criterion of freedom were seven consecutive negative swabs in a week. He pleaded for more simultaneous Schick and swab tests, and more information was needed about isolation of carriers.

Dr. G. BOUSFIELD said that in poor districts the practitioner much opposed giving antitoxin to a patient unless he could prove to the relatives that it was necessary. If a case looked like diphtheria it should be treated as such by the doctor, or he should send the patient to an appropriate place. After having done 15,000 primary Schick tests, he had noticed that they were becoming less strongly positive. Care was needed before treating all the less profuse carriers, as that might upset Nature's balance and interfere with the process of natural immunisation.

Dr. E. A. UNDERWOOD objected to the text-book statement that antitoxin should be given whenever a swab was taken. It was also a questionable policy

to have doubtful cases removed to a fever hospital for observation.

Dr. E. W. GOODALL did not think it necessary to indulge in universal swabbing, and remarked that advocates of this did not include the staffs of fever hospitals. He had not met cases in which diphtheritic whitlows had caused other cases of diphtheria.

Dr. R. A. O'BRIEN thought every effort should be made to shorten the period in making a report on the swab.

Dr. CLARK TROTTER said it was difficult to get the practitioner to understand what he ought to do in cases of diphtheria. On the appearance of one case in a household the family doctor might swab all the other members and all who had been in immediate contact, just because he felt he was expected to do it. To eliminate mixed infections, Dr. Trotter said he was in the habit of giving every case of scarlet fever a prophylactic dose of diphtheria antitoxin; this greatly improved the scarlet fever cases and prevented any possible spread of diphtheria.

SECTION OF DISEASE IN CHILDREN

At a meeting of this section held on Jan. 24th, with Sir LANCELOT BARRINGTON-WARD, the president, in the chair, a paper on

Metabolism, General Nutrition, and Growth in Infancy and Childhood

was read by Dr. E. P. POULTON. He said that the work he had done with Mr. T. W. Adams possibly provided a new way of studying these problems, and he was bringing it before the section in the hope of getting assistance. He had had occasion to recalculate the metabolism results of Benedict and Carpenter from oxygen-consumption and respiratory quotient, and had found that in children these results differed from those obtained by calorimetry. Assumptions from the respiratory quotient were misleading, and he felt that carbon dioxide output should be regarded more truly as a measure of metabolism. By plotting the logarithm of the carbon dioxide against the logarithm of body-weight he found a linear increase up to 18 months, a flattening from 18 months to 4 years, and then a linear increase again. That is, as the child passed from 18 months to 4 years, the carbon dioxide output remained constant while the body-weight increased. A possible explanation was that when the child started walking more actively he lost fat, and metabolism continued thereafter at a slower rate. If this were so, there should be an alteration in the relationship of height to weight at this period, the gain in height increasing as compared with the gain in weight. Dr. Poulton demonstrated further graphs in which the logarithm of height and the logarithm of weight of children from birth to adult age were considered. There were inflexions in the curve when the body-weight reached 10 kg. (22 lb.) between the ages 10 months and 2 years, and again when the body-weight was about 18 kg. (39.5 lb.) at age 4-5 years. A third inflexion occurred at 15 years when body-weight was from 50 to 55 kg. (110 to 120 lb.). The slowing of the weight increase between 1 and 4 years without a proportional slowing in height increase could be explained by loss of fat, and the fact that metabolism remained about constant at this period, despite increase in weight, was regarded as due to the disappearance of *luxus* consumption associated with the fat of babyhood.

The relation of height to weight represented

general nutrition, and could be used with advantage to compare the general nutrition in different types of children and in different strata of society. An important question was whether nutrition was constant in different social strata. Baldwin had collected measurements in the United States which incidentally showed the change in relationship of height to weight at 5-6 years and again at 15½ years. The old figures of Roberts on public-school children and those of artisans showed what was generally agreed, that height and weight bore the same relationship to each other in all classes, so that this relationship could be roughly called an index of growth. There must, however, be a third factor, time, entering into it. It was usual to correlate time or age with weight, but when age and height are correlated there was a much closer agreement with the growth curves. Dr. Poulton showed charts to illustrate this point, taking measurements of boys from an Oxford preparatory school from 8 to 13½ years and older boys from Epsom College. It was interesting that Roberts's figures from the 'eighties, of height and age of boys, at public schools, naval and military colleges, and universities, and medical students, fell below what is regarded as ideal to-day. Fleming and Martin's statistics from Wales, including some elementary school-children, showed lower curves, while Greenwood's from elementary schools all over the country were lower still. Elderton's figures for Glasgow children taken by districts were all graded according to the social status. So in comparing the different classes of the community of varying social strata, while the height-weight curves were constant, the lower classes were less tall for their age, and practically speaking the social status could be graded by this property.

Prof. LEONARD FINDLAY was glad that Dr. Poulton had shown the fallacy of the height-weight index; these two were measurements of two totally different things—the height of growth and the weight of nutrition. There was a real difficulty with regard to standards; comparison of private patients with, say, Baldwin's measurements showed the former as sometimes as much as two or three years above the latter. Rate of growth of height and of weight varied much in different social classes. Another interesting point was the focusing of attention on the first eighteen months of life. In a study undertaken with Prof. Noel Paton, he had found that the rate of growth was strikingly greater during this period, and he thought that in questions of under-nutrition this was the period on which to concentrate if valuable time was not to be lost.

Dr. ALAN MONCRIEFF emphasised again the importance of considering the carbon dioxide output in estimating the metabolism in young children. The oxygen-consumption alone could be very fallacious. Secondly, he complained of the lack of proper growth standards for this country. Some years ago he had collected data from several foreign countries, and had found considerable variations. Yet we were content to accept as a standard figures from the mixed population of America. We could not begin to argue about malnutrition or undernutrition until we had standards for English children. He hoped that the promised and long-awaited anthropometric survey would shortly appear.

Dr. POULTON, in reply, pointed out that the height-weight relationship was only fallacious in so far as it was constant whatever class was studied. Brodie's figures for animals showed a difference between those fed improperly and those on adequate diets,

and he concluded that in this country all children got enough calories, and though a child could gorge himself on bread and gain weight, he would not grow taller. Possibly the difference in height in the different social strata resulted from lack of vitamins, and what was needed was more vitamin A, and perhaps D, rather than more calories. Dealing with the relation of height to weight, the height-age curve was straight, the weight-age curve flattened out, and height should be taken for measurement of growth. He wanted to stress the importance of weighing children naked. There was a real need for reliable observations on children from a statistical point of view.

SECTION OF UROLOGY

At a meeting of this section held on Jan. 23rd, Mr. E. W. RICHES being in the chair, a paper was read by Dr. J. LEON JONA, of Melbourne, on

The Kidney Pelvis

its normal and pathological physiology, illustrated by cinematography and pyelograms. In a preliminary anatomical survey Dr. Jona pointed out that the segmental character of the embryonic kidney was preserved in the adult calyces. These, together with the infundibulum of the pelvis and the ureter, were enclosed by layers of smooth muscle which were found, on pyeloscopy, to contract rhythmically in a manner which the speaker compared with the systole and diastole of the heart muscle. If the pelvis were filled with radio-opaque fluid through a ureteric catheter and observed on the fluorescent screen this action could be followed. The calyces contracted in regular order from above downwards, each contraction lasting from 1 to 3 seconds and being followed by a resting period of similar duration. The infundibulum contracted in a similar fashion and forced the urine down into the ureter. Regurgitation into the calyces was prevented by a kind of "snap" action of the proximal part of the infundibular recess. The cinematograph which followed at this point had been prepared by an artist to whom the speaker had demonstrated the sequence of events in the living subject. The film showed very clearly, by a synthetic series of diagrams, the rhythmic contractions already described.

Aberrations in the regularity of this mechanism were found in a variety of pathological states such as atony, spasm of the whole kidney pelvis, spasm of the ureter at one point, or atony of the ureter. Pyelograms illustrating these different conditions were demonstrated. Spasm was frequently reflex in origin and might be due to disease of the gall-bladder or appendix, inflamed lymph glands, or to an aberrant renal artery. Dr. Jona had even seen spasm of the left ureter in a patient with gall-stones. Atony and dilatation could occur in the absence of obstruction and might be due to the action of the sex hormones. Antiperistaltic waves were frequently associated with spasm of the ureter at one point; they were also observed in the ureters in apparently normal subjects when the bladder was distended and micturition prevented. Such antiperistaltic waves were an obvious mechanism in the production of pyelitis should the bladder be infected. The use of pyeloscopy might assist in the early diagnosis of renal tumours when the only clinical symptom was hæmaturia. In pregnancy the ureters were often enlarged by as much as two-thirds of their normal size, and this was often accompanied by elongation and kinking of the upper or free part of the ureter. Such a con-

dition was liable to persist in association with sub-involution of the uterus. Mr. Harold Burrows's observations on the effects of oestrogenic substances upon the musculature of the ureters were, said Dr. Jona, highly significant.

Dr. Jona demonstrated a graphic method of investigating pelvic pressure and contractility. In this the ureteric catheter is connected with a tambour and a record of the pressure is obtained on a revolving drum. With this apparatus he made a short record, using manual pressure on a rubber bulb in imitation of the conditions which would obtain in practice. Tracings in normal subjects, he said, showed a regular undulating curve corresponding with the rhythmic systole and diastole of the pelvis. A change from the horizontal to the sitting posture caused an appreciable increase in the intrapelvic pressure, as did also an increase of intra-abdominal pressure—for example, in deep inspiration. This graphic method of investigating the muscular activity of the urinary tract was of considerable service in distinguishing between cases of hydropelvis where the muscle would contract and those cases where atony prevailed. In the latter the addition of 10 c.cm. of fluid simply added to the distension without producing an appreciable rise in pressure. In such cases nephrectomy might be advisable, but it should always be borne in mind that if an obstructive cause could be found and removed a great degree of improvement was to be expected in the contractility of the pelvic musculature. The combination of pyeloscopy with graphic records of intra pelvic pressure was of considerable service in estimating the effects of drugs upon this part of the urinary tract. Thus, in one case, in which a tracing was demonstrated, a single dose of pituitrin had been effective in restoring a normal rhythm where dysfunction had previously prevailed. Both atropine and a small dose of histamine would cause a moderate rise of pressure. Acridine and mercurochrome had a similar effect which the speaker attributed to their action upon the muscle rather than to any antiseptic effect. One effect of aspirin was to lengthen diastole.

The observations described had all been made in women. Dr. Jona gave no account of his work on animals apart from a single experiment in which he demonstrated the deleterious effect of using too great a pressure upon the renal pelvis. In this the radio-opaque fluid had penetrated into the inferior vena cava and its branches.

DISCUSSION

Mr. YATES BELL said that in a series of 12 cases of renal pain he had found hypertonus of the pelvis in the majority. In one case, a girl of 12 who had suffered from intractable pyelitis for a period of from 4 to 5 years, an intravenous pyelogram was normal apart from the form of the calyces, which were small and globular. Pyeloscopy showed no contractions, but these were initiated by injecting 0.5 c.cm. pituitrin and, after a course of treatment with this drug, the patient's condition returned to normal.

Dr. N. S. FINZI considered that the modern fluorescent screen and improved X ray apparatus had been of enormous assistance in obtaining effective pyeloscopy. He thought that intravenous Uroselectan had superseded retrograde pyelography too extensively but there were indications that the pendulum was swinging back.

Dr. G. E. VILVANDRÉ suggested that the effects of pyeloscopy might be imitated by taking plates at

more frequent intervals in the course of a pyelogram. Ordinarily exposures were made at intervals of from 10 to 15 minutes; if plates were taken at intervals of one minute a record might be obtained of the contractions described by Dr. Jona. He also suggested that kinking of the ureter was fairly common and not by any means confined to pregnant subjects.

Mr. A. W. CUBITT discussed the bearing of intravesical pressure upon ascending infection of the urinary tract with special reference to cases in which prostatectomy had been performed. In such cases drainage of the bladder led to the conversion of a positive pressure into a negative one. He thought this might facilitate an ascending infection, and for this reason advocated complete closure of the bladder. He also described the relief of pain effected by atropine in a case of vesical stone.

Dr. JONA, in reply, remarked that cases such as Mr. Yates Bell had described were undoubtedly forthcoming if they were looked for. His only objection to Dr. Vilvandré's suggestion was based upon expense, which would be considerable. To Mr. Cubitt he expressed doubt as to whether the pelvis of the kidney would stand a negative pressure.

MEDICAL SOCIETY OF LONDON

Prof. G. E. GASK, the president, took the chair at a meeting of this society held at 11, Chandos-street on Jan. 27th, when Mr. V. ZACHARY COPE opened a discussion on

Acute Appendicitis

Even after the fifty years which had elapsed, he said, since Fitz's famous paper of 1886, the mortality from acute appendicitis was still considerable and did not show diminution. The main problems had always been to decide the best time to operate and how much ought to be done at the operation. J. B. Murphy of Chicago, than whom no one had done more to put the surgery of appendicitis on a sound footing and who had had an operative mortality of about 4 per cent., which would be considered good to-day, had emphasised the great importance of operating on all cases early and before perforation of the appendix. He had called this the first stage of the disease, applying the term "second stage" to that period, for about three days after perforation, when the inflammatory process was increasing and spreading. The operation, he had written, must then be a limited one: simple opening of abscess and relief of pus tension in the affected area, with the removal of the appendix if it were accessible and easily amputated. There should be the least possible separation of agglutinations. When the patient was apparently overwhelmed with intoxication, a simple incision was made and pus tension relieved with a large drainage-tube. In the third stage, the stage of subsidence of the acute symptoms, he had generally operated and let out pus. He had therefore operated promptly in nearly all cases. Where, however, the surroundings or low state of the patient and the absence of a competent surgeon contra-indicated an immediate operation, he had recommended Ochsner's treatment, with the warning that it required a great deal of judgment. Ochsner had aimed at changing a dangerous acute into a relatively harmless condition by inhibiting peristalsis and giving the peritoneum an opportunity to remove the infection by absorption or circumscription. He had not sought to avoid operation but had chosen the most favourable time for it. He had not only operated at once on every case in which he had thought

the appendix was still unperforated, but had often operated promptly upon appendicular peritonitis. For the past thirty years the majority of surgeons had followed the teaching of Murphy. During the last few years, however, a number of the younger surgeons had questioned the wisdom of prompt operation at all stages. They regarded cases in which symptoms had been present for fifty hours as suitable for delayed treatment; they put the patient in the high Fowler position, allowed no purgatives and gave no morphine. They allowed only water by mouth. They did not recommend delay in young children or where the diagnosis was uncertain, and they regarded as additional indications for operation the previous administration of a strong purgative, superficial hyperæsthesia, and obvious general peritonitis.

IMMEDIATE AND DELAYED OPERATION

The advantages of the so-called immediate operation were that the exact pathological condition was ascertained, the infective focus was usually removed, the infective field was drained where necessary, and the patients and relatives were saved a trying delay. Its disadvantages in cases with perforation of the appendix were said to be the danger of spreading the infection, the greater frequency of intestinal obstruction and ileus, and the frequency of secondary abscesses, fecal fistulae, and incisional hernia. The advantage of the Ochsner method was said to be that operation was undertaken when the infection was localised and the risk minimal. Its drawbacks were that if the infection did not become limited the patient might be in a worse state than before; extra work and strain were thrown on all concerned; treatment must be carried out on the threshold of the theatre by the surgeon himself; and delay with mistaken diagnosis might be fatal. There was a great deal of truth in these criticisms, but they were of varying weight.

Mr. Cope said he was doubtful whether statistics could solve the problem of which was the better method, and he thought there was need of a thorough investigation into the whole question of appendicitis mortality by a responsible and impartial body. From his clinical experience, in spite of the comparative and average success of prompt operation, he had from time to time had cases in which delay had seemed to be the better plan. He still always advised immediate operation, not only for the unperforated appendix but also for perforative appendicitis with diffuse peritonitis, so long as the patient was not too toxic and was reacting well to the inflammation. The cases which he decided upon their merits were those with a definite and circumscribed lump and those with advanced peritonitis. If he thought the lump represented a subsiding inflammation with perhaps a small, ill-defined abscess, he sometimes tried the starvation treatment of Ochsner. If he thought there was a well-defined abscess, he usually opened it. With advanced peritonitis and a toxic and dehydrated patient it was better to wait a few hours and sometimes a day or two while the patient was hydrated and detoxicated by intravenous and rectal saline. It would be a retrograde step to teach that delay was the usual correct treatment. Delay should not be practised except by experienced surgeons.

Mr. Cope described his own technique and, in conclusion, recommended that whenever possible an experienced surgeon should be in charge of any case of appendicitis.

EXPECTANT TREATMENT

Mr. R. J. McNEILL LOVE said that in appendicitis that had become limited to the right iliac fossa or

pelvis immediate operation might be extremely difficult. Although a practised surgeon could remove the appendix with the minimum of disturbance, many cases fell into the hands of the less experienced, whose operative results were buried in the records of their hospitals. The main points of expectant treatment were the four "F's": Fowler's position, fomentation, the four-hourly chart, and fluids by the mouth in minimal quantities. He had never felt very happy about fluids by mouth, but preferred intravenous infusion for four or five days. If expectant treatment was adopted for the localised condition, the disease followed one of three courses. In about 65 per cent. of cases the infection subsided and swelling disappeared, and three months later the appendix was removed at a clean operation with negligible mortality. In 25 per cent. of cases an abscess formed, showing that infection had become limited and resistance increased. Expectant treatment could be still carried on, but it was wise to drain the abscess. In 10 per cent. of cases expectant treatment must be abandoned because of increase of pain, tenderness, rigidity, and fever. The surgeon was then faced with the necessity of operating on a more toxic patient. Expectant treatment had been criticised on the ground, among others, that it was impossible to gauge the condition of the appendix. Once localisation had occurred, the surgeon knew something much more important: the condition of the surrounding peritoneum, omentum, and bowel, which were all acting as a wall to the inflammation. Discharging wounds and faecal fistulae were more common after the immediate operation. In suitable cases the mortality following expectant treatment was about 3 per cent. less than that obtained from immediate operation by experienced surgeons. The clean operation three or four months after the acute condition had subsided could be performed safely by a surgeon of less experience.

THE STATISTICAL ASPECT

Mr. H. C. W. NUTTALL, speaking of the statistical aspect, said that with a mortality of 2.53 per cent. he considered that he still had something in hand. Two points of view had to be distinguished: that of the full-time surgeon and that of the general practitioner who did a certain amount of surgery. The latter might easily be taught to operate carefully; it was more difficult to teach him to watch the patient. House surgeons must be taught never to attempt to remove the appendix if there were any difficulty. Hyperaesthesia was of very little value in diagnosis, as it was present in 50 per cent. of cases. The most difficult cases were those in which the condition had been established for some time and the surgeon could not tell where the infection had started and where to make the incision. Mr. Nuttall would still advise operation if the appendix region were incriminated. Some patients suffered severely from thirst unless they were given water by the mouth; to do so made little difference to the abdomen if the drainage were adequate. In the vast majority of straightforward cases he did not drain, but he always drained for the slightest amount of haemorrhage, for a blood-clot in an infected abdomen was very serious. He did not regard the diminution of mortality-rate by 3 or 4 per cent. by the expectant treatment as good enough; the immediate operation gave better results in the end over a large series of cases.

Mr. HUGH WHITELOCKE stated that at the Radcliffe Infirmary, Oxford, the staff delayed operation only in two or three cases a year, yet the figures had improved for two reasons: the introduction of continuous intravenous drip in severe toxic cases,

and the careful suction of local peritonitis, particularly from the pelvis. He had rarely drained by a stab incision over the pubes. By inserting a tube drain to the base of the pouch of Douglas and by withdrawing it about half an inch every day with a slight rotation, almost any pelvic abscess could be satisfactorily drained through a lateral gridiron incision.

Mr. JULIAN TAYLOR adduced as a reason for the low mortality at University College Hospital that the honorary staff dealt with practically all appendix cases. If the surgeon were experienced, it did not matter which principle he followed. The general presumption of the exponents of delayed operation that patients died from the dissemination of infection from an abscess was quite wrong; this was the rarest possible occurrence.

Mr. G. H. COLT said that some drainage statistics which he and a colleague had compiled and shown to a professor of statistics had illustrated the danger of any but a lateral incision. The mortality from an appendix abscess was approximately 3 per cent., but from spreading peritonitis it rose to 80 per cent. at about the tenth day. When the appendix and the more local inflammation had been removed and the operator saw clear lymph pouring into the local focus, he should leave a tube in for a short time; otherwise the risk was less if no drain were used. The difficulty lay in deciding what and what not to leave.

Mr. W. E. TANNER remarked that in some cases where the appendix was bound down to the back of the abdominal wall and the caecal end was healthy he had divided the caecal end, invaginated the caecum, pulled out the mucosa of the appendix, and inserted a drain; the patient was saved a second operation. When a very old patient had an appendix of this type a transfusion of 200 c.cm. of blood would promote local suppuration and the patient would get better. This was far superior to giving vast quantities of fluid intravenously.

Sir JAMES WALTON also considered that the important factor was not so much the method as the man who carried it out. The important thing was the teaching which the surgeon was to give to students. Every general practitioner was likely to regard himself as a skilled surgeon for the purpose of deciding on delay. The enormous improvement in results had been due to the fact that practitioners were learning to send cases up for early treatment. When an abscess was localised and well defined the surgeon should always operate, and the only question was whether the appendix should be removed. There were three factors: what the patient would stand, how difficult the appendix was to get out, and how quickly the individual surgeon could get it out.

Mr. J. E. H. ROBERTS agreed that a new body of statistics should be obtained from hospital surgeons. A form would have to be filled up when each case was seen and the treatment was planned, and the material would have to be submitted to a professional statistician. A clear exudate in the peritoneum did not necessarily mean general peritonitis but might be due to infection passing through the walls of an unruptured abscess. He could not believe that when there was a general infection of the peritoneum and the source of infection continued, it was not advisable to remove the rest of the appendix.

Prof. J. PATERSON ROSS considered that the main argument for delayed treatment arose when the abscess was diffuse in the peritoneal cavity. Even with a diffuse peritonitis he removed the appendix, just as he would remove a rusty nail from an infected knee-joint. After that, the Ochsner treatment was the right one.

REVIEWS AND NOTICES OF BOOKS

Gefäß erweiternde Stoffe der Gewebe

By J. H. GADDUM, Professor of Pharmacology at University College, London. With an introduction by H. H. DALE, Director of the National Institute for Medical Research, London. Leipzig: Georg Thieme. 1936. Pp. 200. R.M.18.

A LARGE number of pharmacologically active substances can be isolated from living tissues. Some of these, for instance the hormones, adrenaline, and pituitrin, are obtained from highly specialised cells and bring about an increase in vascular tone. Others may be prepared from a large variety of tissues and give rise to vasodilatation when injected into animals; it is with these substances that this monograph deals. Sir Henry Dale discusses their general nature and significance in an introductory chapter. Three are chemically well-defined substances of known constitution—namely, histamine, acetylcholine, and adenosine. The evidence is in favour of the view that histamine and acetylcholine, at least, exist in the cells in an inactive combination and are released when the cells are stimulated or damaged; after their release they tend to produce local rather than general effects. A short historical review is given, and it is interesting that these substances were well known chemically before their physiological significance was realised. Prof. Gaddum begins with a very useful section outlining the methods generally available for the study of vasodilators present in tissue fluids and extracts. Histamine, acetylcholine, and adenosine compounds are fully dealt with in separate chapters. A very useful section follows in which substances of unknown constitution present in extracts of various organs are discussed, such as the "heart hormone" of Haberlandt, Kraut and Frey's "kallikrein," and Gley and Kisthinos's "angioxyl." The evidence for the separate identity of these various substances is examined critically, and the information provided will be of particular interest to clinicians who are offered preparations containing such substances as their active principles. These earlier sections are likely to be used mainly for reference purposes; the later ones have a more general interest.

In recent years evidence has rapidly accumulated showing that the action of many nerves is brought about through the liberation of chemical substances at their endings, a conception which though not new had previously been based on scanty experimental data. Convincing evidence in favour of this view is given and the whole subject is fully reviewed. Sir Henry Dale has coined the term "cholinergic" for nerves in which acetylcholine or some closely related substance is the transmitter, and there is now evidence to show that probably all pre-ganglionic autonomic fibres and all post-ganglionic parasympathetic fibres are cholinergic, as are the motor nerves to striped muscle. "Adrenergic nerves," that is to say, nerves which act as if adrenaline or some related substance were produced when they are stimulated, are also dealt with in this section, although strictly they do not come under the general title of the monograph. In the final chapter recent additions to our knowledge of several topics of general interest are outlined, including local chemical mechanisms regulating the circulation, anaphylaxis, and traumatic shock.

An excellent bibliography is provided and a good index. The book is indispensable to those working

on pharmacological or physiological problems, and contains much information of value to the physician (who can read German) interested in the fundamental bases of medicine.

Essentials of Cardiography

By H. B. RUSSELL, M.D., M.R.C.P. Lond., Medical Officer in Charge of the Cardiographic Departments at St. Thomas's and the Royal Masonic Hospitals, London: J. and A. Churchill Ltd. 1936. Pp. 82. 7s. 6d.

THIS small book contains the essentials of electrocardiography and of radiological examination of the heart (orthodiagraphy) presented in an elementary form for the use of students.

In the first section, the different types of normal and pathological electrocardiogram are portrayed and simply yet clearly described. With a few exceptions the illustrative records are quite good, but the deflections are unlabelled which is a serious defect in a book intended for students. The second section of the book, dealing with radiology, is elementary but not very accurate. Some of the illustrative orthodiagrams are crude and the interpretation given is in several instances open to question. The anatomical diagrams might have been better, and that of the first oblique position is incorrectly labelled. Enlargement of the left auricle is not described, though it is mentioned as affecting the left heart border. The value and importance of radiological examination of the heart exceeds that of electrocardiography to-day, and some account of the method is required by students. If this section of the book were improved and slightly expanded, it would fulfil this requirement.

Principles of Bacteriology

Sixth edition. By ARTHUR E. EISENBERG, A.B., M.D., Director of Laboratories, Sydenham Hospital, New York; Member, New York Pathological Society, New York; and MABEL F. HUNTLY, R.N., M.A., Director of Nursing, Wesson Memorial Hospital, Springfield, Massachusetts. With annotations and a section on Microbic Variations by F. E. COLIEN, M.S., Ph.D., Professor of Bacteriology, Vocational School, Milwaukee, Wisconsin. London: Henry Kimpton. 1935. Pp. 378. 12s.

THIS is an American work designed as an introduction to Bacteriology for Nurses. In this country it would be considered unsuitable for such a purpose as it is against our educational rule to demand so much in the way of theoretical knowledge from nurses, most of whom have had but scanty general scientific training to serve as a foundation. This book is not likely to arouse enthusiasm for the American system of instruction. We find, for example, descriptions of such uncommon diseases as coccidial granuloma and sprue (said to be due to monilia!), but the treatment of such interesting and important subjects as diphtheria or streptococcal disease is quite inadequate. What can a nurse profit by reading a few paragraphs on such highly uncertain subjects as local immunity, Rosenow's elective localisation or bacteriophage, not to speak of the side-chain theory, bacterial variation, or the technique of the Wassermann reaction? An unfortunate feature of the book is the form in which many of the questions are put; a statement has "T"

and "F" written in front of it with the instruction to circle the "T" if the statement is true, the "F" if it is false. Here are a few examples. "The gonococcus is a streptococcus," "Dr. W. H. Park is the head of the New York Board of Health Laboratories," "Drs. George F. and Gladys H. Dick found the cause of pneumonia to be a streptococcus." We know that nurses often have to do their reading when they are too tired for any mental effort, but this is surely going too far in "spoon-feeding." It might even dawn on the tired reader that if she answers sufficient questions and uses the throw of a coin to make her decisions she will be practically certain to score a comfortable 50 per cent. It is fair to say that as the book has reached a sixth edition it cannot have failed in the purpose for which it was intended.

Modern Sociologists

1. PARETO. By FRANZ BORKENAU. London: Chapman and Hall. 1936. Pp. 219. 6s.

2. TYLOR. By R. R. MARETT, M.A., D.Sc., LL.D., Rector of Exeter College, Oxford. Same publishers. 1936. Pp. 220. 6s.

THESE two volumes owe their production to recognition by the publishers of a growing interest in social science, and the result is the issue of a series of sociological studies under the general editorship of Prof. Morris Ginsberg, professor of sociology in the University of London, and Mr. Alexander Farquharson, general secretary of the Institute of Sociology of London. The books are not intended to serve only as students' text-books, but the selection of both authors and subjects has been made with a view to supplying a systematic introduction for any intelligent reader to the best of modern thinking about the social world in which we live and work.

1. Pareto, born in 1848, was of aristocratic Italian descent, but his father was for some years a refugee in France and the son began his education in Paris. The father was a Mazzinist but the son showed marked antagonism towards the family tradition. Pareto became an engineer and while quite young obtained a considerable position in his calling, but he was never able to make his opinions fit with his career. He was caught between a government which was not renouncing economic State intervention and the revolutionary Socialist party. His attacks on economic protection developed into attacks on the government, and his situation became impossible. Being a comparatively rich man he retired from public life, and by a fortunate accident secured a chair at the University of Lausanne, whence came a series of writings whose bitterness was due to his position between two incompatible attitudes, but whose teaching was none the less valuable. Pareto died when Fascism had been only a year in existence so that, although in many directions his views might have coincided with Fascism, there is hardly evidence strong enough to justify the claim of the Fascists that Pareto was their chief precursor. Dr. Borkenau's closely explanatory description of Pareto's teaching will be welcomed by students of sociology.

2. Edward Tylor was a Quaker and was taken away from school too young to make it likely that he would develop into a scholar in the narrow sense of the word. In the widest sense he became a pre-eminent scholar, for admittedly his studies in anthropology made him the most learned man of his day over the vast field implied, though evidence forthcoming during the 20 years since he died would have extended his outlook and might have modified some

of his theories. His studies originated in a happy and accidental meeting in Cuba with the famous ethnologist Henry Christy. They travelled through Mexico together and Tylor's first book, "Anahuac," records their experiences. In 1860 he showed himself the learned anthropologist that he already was, in a volume entitled the "Early History of Mankind," published in 1865; here he proved the width and importance of his studies, and when in 1871 the classic work "Primitive Culture" appeared he became celebrated, gaining election as an F.R.S. while still under 30, and shortly afterwards the D.C.L. Oxf. Prof. Marett's exposition of Tylor's work makes good and valuable reading. Such chapters as those on Society and on Material Culture show how great a man Tylor was and the important directions in which he was a pioneer, and the chapter setting out the connexion of religion and animism explains a direction of Tylor's researches with which his name is especially associated. This is a really useful little book.

A Doctor's Odyssey

A Sentimental Record of Le Roy Crummer: Physician, Author, Bibliophile, Artist in Living, 1872-1934. By A. GAYLORD BEAMAN. London: Humphrey Milford, Oxford University Press. 1935. Pp. 340. 11s. 6d.

THIS is an intimate picture of a man who had a large number of medical friends and connexions and deserved his position and popularity. Physician, book-collector and virtuoso, traveller, artistic critic, and gourmet, he touched life at many angles and always received and communicated impressions. The author describes the biography as "a sentimental record" and plays Boswell to his Johnson with admiration and without criticism. The chapter describing in detail the collection of books which Dr. Crummer made includes interesting notes on his activities as a collector and repeats his amusing little estimates of characteristics of both the shop and the shopkeeper at the various marts which he visited. The Crummer collection is now in the possession of the University of Michigan and will there remain a memorial of a very interesting personality.

Quarterly Journal of Medicine

THE January issue contains the following papers:—
Erythrocyte Sedimentation-rate in Diseases of the Heart, by PAUL WOOD (see p. 271).

Observations on the Treatment of Myasthenia Gravis:—A. M. COOKE and R. PASSMORE give the results of the use of various therapeutic measures on myasthenia gravis in a girl of 13 years. They found that glycine, acetylcholine, and Parathormone produced no clinical improvement, whereas Prostigmin by injection led to complete relief of symptoms for four hours, while eserine and ephedrine by the mouth gave a lesser but much more prolonged improvement. They also studied the creatine and creatinine metabolism in this patient and formed the opinion that the biochemical lesion is not an inability to form creatine from its precursors but rather an inability to metabolise creatine properly.

Glycogen Disease (von Gierke's Disease) by R. W. B. ELLIS and W. W. PAYNE.—This paper is illustrated by a detailed account of seven cases. The familial incidence of many of them is demonstrated and it is suggested that the condition may possibly be inherited as a Mendelian recessive character.

Two Cases of Muscular Degeneration Occurring in Late Adult Life.—S. NEVIN reviews the recorded cases of late progressive muscular dystrophy. Pathological and biochemical examinations of the affected muscles obtained at biopsy were made on these two cases, and changes were demonstrated differing at least in degree from those characteristic of progressive muscular dystrophy.

Achrestic Anæmia.—M. C. G. ISRAËLS and J. F. WILKINSON give an account of a group of cases of megalocytic anæmia which do not fit into the categories so far described; closely resembling pernicious anæmia, but differing from it, especially in course, prognosis, and treatment. This class of anæmias they term "achrestic" because they seem to represent a failure to utilise the anti-anæmic principle. The distinguishing characteristics are shown to be a megalocytic anæmia, the presence of free HCl in the gastric juice, failure to respond properly to anti-anæmia therapy, megaloblastic hyperplasia of the bone-marrow, and a prolonged course, eventually fatal.

Leucocytosis in Typed Lobar Pneumonia.—JOHN FLEMING reports observations on the leucocyte count in pneumonia on a series of cases in which the special type of pneumococcus concerned has been determined. He is able to show that during the first three days of illness a leucocytosis of over 20,000 is characteristic of most cases of Type I. lobar pneumonia, while a leucocytosis of less than 20,000 is usually found in Type II. pneumonia; further, that the leucocyte count is of prognostic value when the type of organism, the age of the patient, and the duration of the illness are all considered.

Gargylism.—R. W. B. ELLIS, W. SHELDON, and N. B. CAPON describe a syndrome characterised by bone changes, a peculiar facies, congenital clouding of the corneal, abdominal distension with enlargement of the liver, spleen, and mental deficiency. They report in detail seven cases personally observed, and review ten cases from the literature.

British Journal of Surgery

THE January issue (Vol. XXIII., No. 91) contains the following papers:—

Spondylitis Ankylopoietica, by F. CAMPBELL GOLDING (London). An account of the radiological findings in 91 cases. Early joint and muscle pains occurred in the majority; the opinion was reached that sacro-iliac disease antedated by several years the spinal changes.

An Improved Technique for the Introduction of Radium Needles in the Treatment of Carcinoma of the Breast, by R. BROOKE (Chichester). The radium needles are contained in hollow trocars passed through the breast substance and fixed at each end in a rigid frame.

Further Observations on the Disturbance of Metabolism Caused by Injury, with particular reference to the dietary requirements of fracture cases, by D. P. CUTHBERTSON (Glasgow). A diet rich in first-class protein and of high caloric value appeared largely to mitigate the drain on the body nitrogen.

Œsophagectomy for Carcinoma of the Thoracic Œsophagus, by E. S. J. KING (Melbourne). Report of a successful operation by the transpleural route; preliminary gastrostomy and artificial pneumothorax had been performed.

Gastric Diverticula, with report of a case before and after operation, by G. A. EWART and G. R. MATHER CORDNER (London). Clinically there is no characteristic picture, and the operation is difficult. The X ray diagnosis is discussed in detail.

A Method of Treating Fractures of the Lower Limb: Use of a Combined Counterpoise and Traction System with a Thomas Leg Splint and Hinged Knee-piece Attachment, by A. LEWER ALLEN (Johannesburg). The splint is so suspended that it is used as a finely balanced, first-class lever, the site of fracture and the fulcrum coinciding.

Renal Rickets and Dwarfism: A Pituitary Disease, by BRUCE CHOWN (Winnipeg). In two cases described the association of dwarfism, polyuria, and urinary tract dilatation suggest a pituitary-diencephalic lesion. Such a lesion was found in the second case. The nephritis is regarded as secondary to an abnormal mineral metabolism.

Isolated Dislocation of the Base of the Fifth Metacarpal, by NORMAN ROBERTS and C. THURSTAN HOLLAND (Liverpool). Forward and inward dislocation (three cases reported) is easily reducible by traction, but requires prolonged extension. Outward dislocation into the palm (one case) may require open operation.

Rupture of the Long Head of the Biceps Brachialis, with notes on four cases, by H. A. H. HARRIS (Chelmsford). Two cases were successfully treated by suture of the long head of the biceps to the coracoid process of the scapula.

Progressive Post-operative Cutaneous Gangrene, by H. T. COX (Manchester). A case is reported which showed extensive sloughing and a definite zone of black gangrene. Histologically the process was limited to the true skin. Operation was successful.

Intravenous Pyelography in a Series of Cases after Transplantation of the Ureters, by G. GREY TURNER (London) and J. H. SAINT (Newcastle). Investigation in six cases showed satisfactory renal function in five; in one only was there impairment on both sides, and that was partial. The action of the whole colon as a urinary reservoir was demonstrated.

A Gridiron Access to the Biliary Apparatus, by C. JENNINGS MARSHALL (London). An external rectus incision is carried down to the posterior layer of the rectus sheath and through the posterior lamina of the internal oblique aponeurosis. The transversalis is divided by transverse incision.

Mucoid Carcinoma of the Cæcum in a Boy of 13 Years, by ROBERTSON F. OGLVIE (Edinburgh). The diagnosis at operation was tuberculosis of the cæcum. Death occurred by generalised metastasis.

Anterior Dislocation of the Hip, by J. A. MACFARLANE (Toronto). Open operation was required in a case of suprapubic dislocation, although attempts at manipulative reduction were made immediately after the accident.

Calcified Cyst of the Pericardium, by A. DICKSON WRIGHT (London). A hæmatoma, caused by a blow with a hockey-ball, became encapsulated and calcified. Successful removal is reported.

A Chloride-secreting Papilloma of the Gall-bladder. A Tumour of Heterotopic Intestinal Epithelium: with a critical review of papilloma of the gall-bladder, by A. B. KERR and A. C. LENDRUM (Glasgow). Cholecystostomy was followed by such excessive chloride loss as to prove fatal.

The Treatment of Acute Mammary Abscess by Incision and by Aspiration, by R. J. V. BATTLE and G. N. BAILEY (London). A method is described of treatment by repeated aspiration and washing out with Dakin's solution. The indications for this method and for incision are discussed in five types of breast abscess.

The Influence of Œstrogenic Compounds in Causing Hernia and Descent of the Testis in Mice, by HAROLD BURROWS (London). Œstrone has been found to inhibit or prevent descent of the testis. Scrotal herniæ are induced by every potent Œstrogenic compound, but only in the presence of a mature or nearly mature testis.

An Experimental Method of Providing a Collateral Circulation to the Heart, by LAURENCE O'SHAUGHNESSY (London). A pedicled omental graft has been applied to the surface of the heart, the experiments being carried out in 14 cats and 2 dogs.

There is an account of a visit to the surgical clinic of the St. Vincent's Hospital, Melbourne; and also reports on cases of special interest and rarity.

AN INTERESTING AMALGAMATION.—A notice appears in the current *Riforma Medica* announcing an amalgamation for subscription purposes of the three Italian medical journals, *Il Policlinico*, *La Riforma Medica*, and *La Minerva Medica*. The communication points out that such a conjunction offers to the medical profession the opportunity of keeping in touch with all professional activities in much more convenient circumstances through the medium of the three great magazines. The combined subscription to the three journals is 150 Lire in Italy, and the subscription can be sent to the managers of any of the three papers; it can be made in two sums of 75 Lire each, the first of which is due now, the second instalment falling due on June 30th. Subscribers to the three periodicals will not only receive the journals at this reduced price, but will be allowed a discount of 10 per cent. on all the publications of the journalistic group P.R.M. It is suggested that by placing the subscribers in a position to estimate the progress of medical literature in a very convenient manner they will reap advantage, while the journals will be able to realise through the union a valuable conjunction of work and influence and stability.

THE LANCET

LONDON: SATURDAY, FEBRUARY 1, 1936

PHYSICAL STANDARDS IN INDUSTRY

IN his opening address on Jan. 24th to the newly formed Association of Industrial Medical Officers Sir DAVID MUNRO remarked how difficult it had been since the war to obtain systematic data about the physical condition and state of health of any large groups. The report by National Service medical boards upon the physical examination of 2½ million men of military age in 1918 had given rise to alarm at the time, but statistical criticism had since shown that except for youths of 18 the examinees could not be regarded as a representative sample of the nation's manhood. But that census did show a mass of remediable defects among those of an age to start on an industrial career; and recent rejections of recruits for the Army and Air Force told the same story. At the head of the causes for rejection stood such items as loss and decay of teeth, deformities of feet, defects of vision and hearing—in particular middle-ear disease—and heart trouble, many of them remediable defects. Prof. E. P. CATHCART's investigation for the Industrial Health Research Board included measurements of height, weight, and strength in men representative of every section of the working community, but it had not been found possible to correlate these measurements with the disabilities causing rejection, although again there was no question of the magnitude of the remediable defects. Bearing all this in mind, Sir DAVID went on to suggest that medical officers in whole-time employment with industrial firms were probably better placed than any other scientific men or administrators for getting information about physical fitness or unfitness. What he would like to see was some system of setting out essential data of physique and disabilities found on entry and of recording them on some kind of agreed form, so that the data collected would be comparable firm by firm. It should also, he hoped, be possible to keep a record of the numbers rejected and of the causes of rejection, which would throw light on the known gaps in our existing health services. He would also like to see the data of physical states at entry and causes for rejection, followed by a comparison of those who are successful in industry, entered on these standards, with an unsuccessful group. If a medical record of sickness could be kept for every one of the personnel followed up, it would surely throw much more light than we have at present on the causes, incidence, and prevalence of occupational disease; and here again the entries should be on an agreed form comparable between one firm and another, for the key to advance in knowledge of occupational disabilities is accurate diagnosis. What he was suggesting was in fact a

piece of combined research in which the Research Board could assist. The first step towards such collaboration would be for medical officers to send to the Board such records as they now keep; with the aid of expert medical statisticians it should then be possible to see what can be made of existing systems and what is required for coördinating further information. Sir DAVID MUNRO touched on the difficulty, well known to the Research Board, that operatives are shy of medical examinations. These objections on the part of the worker (to quote the introduction to one of the Board's annual reports) are easy enough to understand and are due partly to the spectre of unemployment which is always before his eyes and partly to there being many things about medical examinations, as he has experienced them, which offend his sense of fair play. To both of these factors is due a suspicion that, if the slightest physical defect is shown in the examination, it will be recorded against his name, and should the management have anything against him it will serve as an excuse to get rid of him; for he must know that physical unfitness is often an excuse for dismissal. Sir DAVID was hopeful that the Association would be able to collect the information without exciting prejudice. What he had in mind was strictly a piece of research. There was no intention of making an official collection of sickness statistics in rivalry with those of the Ministry of Health and the General Register Office.

RADIOLOGY IN RELATION TO OBSTETRICS

ALTHOUGH in the past few years, as the result of improvements in apparatus and the development of new techniques, the place of radiography in the study of the pregnant woman has been generally realised in continental countries and in America, obstetricians in this country have not availed themselves of radiographic facilities to the same extent. At combined sections of the Royal Society of Medicine, where the subject was discussed last week, Prof. FLETCHER SHAW divided the blame between the obstetrician and the radiologist; while the one had been slow in utilising radiological methods, the other had been slow in developing the technique. It would now appear that the obstetrician is at last becoming cognisant of the great help he may receive from X ray examination of his patients; introducing the discussion Prof. D. DOUGAL said that in every maternity hospital it was essential to have a radiological department equipped and staffed for diagnosis and research. It is to be hoped that this standard will now be generally accepted, sight not being lost of the fact that X ray examination is supplementary to but does not supplant thorough clinical examination. Further, in order that the utmost may be obtained from his work, the radiologist should be in full possession of clinical data about the patient, since in all radiological investigations it is by correlation of the clinical and radiological evidence that the ultimate diagnosis is reached. In addition, if antenatal radiography is to advance, the radiologist should

be informed of all pertinent events subsequent to his examination; from a consideration of these he will learn what modification in technique may be required to get even better results. In the early months of pregnancy a positive diagnosis may be established by radiography at the sixteenth week; by this time the vertebral bodies and the vertex of the skull are ossified sufficiently to cast characteristic shadows. It is perhaps not too much to hope that further refinement in technique may demonstrate foetal parts as early as the twelfth week. The Aschheim-Zondek test is positive much earlier than this, but the demonstration of foetal parts is incontestable.

Radiographic pelvimetry has proved its value; with radiograms taken under standard conditions it is possible by a simple calculation to determine the diameters of the pelvis. Measurements should be made as early as possible before the uterine contents obscure the definition. At the same time as the pelvic diameters are ascertained it will be possible to exclude deformities of the pelvic inlet, whether due to congenital abnormalities, skeletal dystrophies, or local bone disease. The information thus gained may lead the obstetrician to anticipate difficulties which might be encountered when labour commences. As gestation advances radiography is of help in determining multiple foetuses, in recognising abnormalities of the foetus, and in estimating the maturity of the foetus more accurately than can be done by calculation from the date of the last menstrual period. Towards term the position and presentation can be shown on the film, information that is not always certain even when the clinical examination has been made under general anaesthesia. About the value of cephalometry or the mensuration of the foetal head there is more difference of opinion; during labour it is the bony pelvis which is rigid, whereas the foetal head is capable of alteration in its diameters. But Dr. L. N. REECE is confident that cephalometry may be used to fix the last moment at which the head will pass through the birth canal. In the diagnosis of placenta praevia two radiographic methods are available. In the first the amniotic fluid is rendered radio-opaque by the injection of a medium like Uroselectan B when the placental site will be shown as a defect in the shadow of the amniotic fluid; this method, known as amniography, is not free from the risk of inducing premature labour and foetal death. In the second method the bladder is filled with a solution of sodium iodide, when a central or marginal placenta praevia is revealed by an alteration in the position of the shadow of the foetal head in relation to the superior outline of the bladder. In the diagnosis of pyelitis of pregnancy help may be had from intravenous urography in assessing the excretory power of the kidneys and the degree of enlargement of the renal pelvis, their calyces, and the ureters; when the diagnosis has been made serial urograms may be used as a guide to treatment. Over and above all this, should the pregnant woman present signs or symptoms of intrathoracic mischief the radiologist should be called in.

It has been argued that antenatal radiography is unnecessary since the majority of labours terminate normally, but as Prof. DOUGAL remarked at the R.S.M. discussion this argument would apply just as much to clinical pelvimetry. And surely the early recognition of abnormalities, maternal and foetal, will do something towards reducing mortality? The demonstration of multiple foetuses will prepare the mother for unexpected additions to her household, while the demonstration of foetal abnormalities will prepare the obstetrician for difficulties in the conduct of the labour and may in some instances lead to the induction of premature labour. Reckoned in terms of money, X ray examination looks expensive in comparison with other methods of investigation; but its routine use would soon bring down the cost considerably, and complications avoided should be entered on the credit side.

AN ELOQUENT GOOD-BYE

A FEW days ago Lord HORDER marked the end of his term as physician to St. Bartholomew's Hospital by addressing his colleagues at the hospital and the students in a farewell address. The address, with which the issue of THE LANCET opened last week, is an able review of the situation of clinical medicine, in which the author traces in wise and witty terms the main reasons for its present position, and closes by pointing shrewdly to a place where the clinical training of students might well be and could easily be bettered.

The orator testified to being a personal witness in his own time of three great advances in the science and art of clinical medicine which have rendered the doctor of greater service to the patient. That he would mention two of these advances would be immediately guessed, for it is plain how immeasurably, whether in the field of the internal physician or in that of the surgeon, precision of diagnosis and treatment has been gained through radiology; and equally plain is it that the correlation of laboratory methods with ward work has brought about similar enlightenment to the physician of the day that was denied to an older generation. But to the wisdom and skill of that older generation Lord HORDER paid tribute when he pointed out that, although deprived of the opportunities for more accurate knowledge enjoyed by their successors, they were able to meet difficult situations often in an astonishingly pertinent manner through cultivated powers of observation. Consultation of obituary notices of our forefathers will show how often they had impressed their contemporaries by their apparently intuitive knowledge; apparently they guessed, for it might happen that the surmise turned out to be correct when its author could not supply hard-and-fast reasons, but really they were deducing their view from things detected by their sharpened senses, though unrevealed to those less fortunately endowed. The other factor to which Lord HORDER attributed the main progress in clinical medicine is relevant here. It is the increased frequency of and greater thoroughness in post-mortem examinations. "The clinician,"

he says, "began to think morbid-anatomically." That is exactly what the old observer was doing, though he had not the same chances which his modern example enjoys of ascertaining in the dead-house whether his solution of the cross-tissue lights had been correct. It is clear from older medical literature that great importance was attached by many physicians to the lessons of post-mortem pathology, but the facilities for learning the lessons of the post-mortem room were even in times comparatively recent very scanty at many institutions. It is a notable advance in clinical medicine that the better opportunities should be more generally utilised.

Particular attention may be drawn to Lord HORDER's suggestion that in one place the medical education of the senior student could be definitely improved to the saving of his time, and the advance of his appreciation of clinical work. His actual words are:

The fundus oculi and the membrana tympani are normal anatomical structures, yet few clinical clerks have ever seen them before they enter the wards and, largely as the result of this fact, some have not seen them clearly even when they leave. We could profitably exchange the time spent over theories of colour vision and the intimate structure of the organ of Corti for these important matters. The blood-cells are a part of normal histology, but they have rarely been counted, or, if they have, it has only been during the demonstration of the Thoma-Zeiss pipette. The contours of the abdomen, the reflexes

and tendon-jerks, the normal gait, the surface markings of the lungs, the deposits that may occur in urine apart from disease, the flora of the faeces in health . . . is it really economical that the time of the clinicians—and of the senior clinicians—should be taken up in teaching about these things?

Similar observations have been made by the orator himself and by others in the recent discussions of the medical curriculum. And in the many places in which practical reform has lately taken place no doubt the criticism has been met, but it is a point which all teachers in all schools might well remember. While abstaining almost wholly from reference to himself in his eloquent farewell words, Lord HORDER, we may be certain, is here alluding to a situation in medical training, the effect of which he has often felt personally. To a great teacher nothing is more baulking than to find that the lessons which he is striving to convey are rendered of little use to his audience by their lack of fundamental knowledge, and all the members of hospital staffs will remember to have been hampered in their educational work in this manner. Also many a man, looking back on his career as a student, will wish that he had been made to lay down as part of his regular routine that foundation for work which later he was compelled to construct, as best he could, beneath an erection already to some extent elaborated. Lord HORDER's words are very timely.

ANNOTATIONS

WHAT'S HIS NAME?

It is in keeping with current tendencies in medical psychology that disorders of memory are chiefly regarded from the standpoint of emotional interference. Where a memory has been lost or falsely recalled, it is in such mechanisms as repression that we are apt to seek the explanation, unless concussion or some other crude damage is to blame. Engrams and biological memory do not preoccupy us as they did the readers of Semon, although the ancestral memory of Jung and the organic mneme of Rignano are not far removed from Semon's conceptions. Among non-medical psychologists to-day there are some who have studied the development of memory in young children; but there are few, medical or otherwise, who have investigated how this function behaves during the later life of a normal person. To read psycho-analysts, one might suppose that a man would have every experience from the cradle to the analytic hour available to memory, if only the appropriate conditions for its recall could be analytically brought about; to read the psychiatrists, one might suppose that between the extremes of arterio-sclerotic or senile dementia on the one hand, and the boasted mental vigour of a Cornaro on the other, there is no change in the powers of memory that one may look for among men who had reached or passed middle life, no failure that comports with the slow physical changes that betoken age without presaging decay. Yet we all know, in ourselves or our intimates, how insensibly the recalling of names and dates becomes less prompt and easy as the fifties pass into the sixties. It has been pointed out that such a falling-off may be compatible with

continuously productive mental work within an accustomed sphere, though unexpected demands upon the memory, or emotional disturbance, will be likely to accentuate the affection. It is perhaps significant that some elderly writers on these topics have said that the function of memory is in a certain regard inversely proportional to intelligence; people with exceptionally good memories produce nothing new because they do not "work over," and unconsciously modify, their material as less gifted people do. Hence, thought Kraepelin, the few hours of sleep that these fellows of prodigious memory usually require; they do not have to use sleep for working over their memories, as the rest of us must. Forel declared that forgetting is one of the conditions of intelligence. Against these partial views may be set the words of Pascal, a man as phenomenal in memory as in intelligence, who wrote (*Pensées*, Article XXV., 14): "La mémoire est nécessaire pour tous les opérations de l'esprit." Certain it is, that to be unable to recall at need is a provoking experience to those who have been accustomed to find their memories loyal and prompt. The order of these lapses is unclear. Although for the grosser defections, Ribot's law of regression may suffice, the much commoner elusiveness of names must be brought under some other rule. Bleuler,¹ unrepentant apostle of associationism, would have it that substantives go first, and especially concrete ones, because in them the word is less important than in the case of verbs and conjunctions and other indications of a relationship; for the mental representation of the concept "Jackson" or "table" the word is

¹ Bleuler, P. E.: *Naturgeschichte der Seele*. Berlin: Julius Springer, 1932.

scarcely necessary, the image of the object sufficing, whereas in the case of abstract images the word supplies the simplest and clearest component which can easily release definite associations or can itself be stirred readily from without into activity. Bleuler's treatment of the matter raises issues that can scarcely be studied without regard to the verbal and nominal losses in aphasia—and to begin to discuss aphasia is to open the floodgates, if not to plunge into the bottomless whirlpool.

ROUTINE EXAMINATION OF MILK FOR TUBERCLE BACILLI

WHEN milk is to be tested by guinea-pig inoculation for the presence of tubercle bacilli the technique adopted must depend on a compromise between accuracy and expense. A single guinea-pig is liable to die prematurely, and if there are very few bacilli in the milk they may not produce lesions in every animal. An attempt has therefore been made by Mattick and White¹ to estimate the increase in efficiency obtained by inoculating two guinea-pigs per sample in place of one. Their findings are based on examination of 4775 samples, of which approximately 3100 were bulk samples while the rest came from individual cows. From the results it is calculated that if 1000 bulk samples were tested by inoculation of a single guinea-pig 84 reinvestigations would be needed because of premature death whilst 62 positive samples would be falsely reported as negative. If two guinea-pigs were used instead of one, only seven reinvestigations would be needed because of the premature death of both animals, and only four false negative results would be returned. These figures make very clear the advantage of using two experimental animals for every sample. Another question concerns the actual technique. In the present investigation the deposit from 75 c.cm. of milk, centrifuged for 20 minutes at 3000 r.p.m., was emulsified in 5 c.cm. of saline and divided between two guinea-pigs. It may be asked why the test should not be made more sensitive by inoculating each animal with all the deposit from 75 c.cm. of milk; this would not add much to the expense of the test though it would of course increase the labour of centrifugation. Mattick and White do not comment on this point, but there are two obvious objections to the use of large quantities of milk. First, by doubling the strength of the inoculum, the amount of extraneous matter, other than tubercle bacilli, is doubled and the chance of intercurrent infection thus increased; for the observations recorded show that the amount of dirt in the inoculum influences the probability of premature death. Secondly, the problem of transit of samples may make it difficult or even impossible to obtain large quantities of milk. Against these objections must be weighed the undeniable advantage of increasing the concentration of tubercle bacilli by doubling the volume of milk tested. In the present experiments each pair of guinea-pigs was kept in a single cage and out of the 9550 which were inoculated about 10 per cent. died prematurely. This figure, which agrees with those given by other workers, might well be lowered if only one animal was kept in each cage, but the extra attention and accommodation required might neutralise the economy.

It is noteworthy that in Mattick and White's inquiry only 13 per cent. of samples taken from cows suspected, on clinical grounds, of suffering from

tuberculous mastitis proved to be excreting tubercle bacilli in the milk. Superficially this figure reflects upon the value of the routine clinical examination of udders for suspicion of tuberculosis. But it must be remembered that tuberculosis is only one of several common causes of chronic mastitis and the symptoms of tuberculous mastitis are by no means characteristic. In all cases of doubt a sample must be sent in for laboratory examination and this may well account for the low proportion of positive returns.

RECURRENT PAROTID SWELLING

MUCH attention has lately been paid to recurrent swelling of the parotid gland, partly in the hope of elucidating its pathology and partly to show that it differs from epidemic parotitis. The newer methods of investigation, such as sialography, and the examination of catheter specimens of parotid saliva, have thrown some light on the condition, but the various investigators have naturally tended to emphasise different aspects of the problem, and their data are not always comparable.

The diagnosis is used to cover all cases of periodical or recurrent enlargements of the parotid, irrespective of the frequency or duration of the attacks or the underlying lesion. In 19 such cases studied by Payne,¹ no fewer than 16 of the patients were women, the average age at onset being 29, and the average duration of symptoms nine years. As a whole, the group showed nervous instability, and there were wide variations in their attacks. Characteristic changes were found in the saliva, which was always infected (most commonly with *Streptococcus viridans*) and sialography demonstrated equally characteristic changes in the ducts, strongly resembling those of bronchiectasis. Similar cases have been recorded by Pyrah,² and more recently Pearson³ has described a series of 17 cases, 13 of them in children under twelve. This series differs from those previously described not only in age-incidence, but also in the preponderance of males and the rapidity of appearance and disappearance of the swelling in many of the children. Pearson divides his cases into non-infected and infected, but it is not clear whether bacteriological culture of the saliva was carried out in all of them. Sialography in both groups showed changes like those recorded by Payne. In a large proportion of the cases there were associated symptoms attributable to allergy (e.g., asthma, hay-fever, or urticaria), and the saliva of one patient during the attacks contained plugs packed with eosinophils. In this connexion the report of Meyer⁴ of a familial history is interesting; his patient, the mother, and the great grandmother had all suffered from recurrent parotid enlargement.

From the practical point of view, two facts are especially important. The first is that many of the cases are diagnosed and treated as mumps, or as recurrent mumps, though it is doubtful whether there is ever a second attack of mumps. Secondly, it is noteworthy that gross suppuration is rare, although the local condition may be disconcerting, and the immediate prognosis is therefore good. The separation of these cases from recurrent swelling of the parotid due to calculi should not be difficult, but swellings of the same kind have been recorded in toxic conditions such as lead-poisoning or in association with the use of iodine or mercury. Similarly,

¹ Payne, R. T. : THE LANCET, 1933, I., 348.

² Pyrah, L. N. : Brit. Jour. Surg., 1933, xx., 508.

³ Pearson, R. S. B. : Arch. Dis. Childhood, October, 1935, p. 363.

⁴ Meyer, H. S. : Jour. of Pædiat., 1934, iv., 248.

¹ Mattick, A. T. R., and White, P. : Med. Officer, Dec. 28th, 1935, p. 265.

they should be readily differentiated from the occupational enlargements of the parotids seen in glass-blowers and players of wind instruments and occasionally in malingerers, for in these the swellings are pneumatocoeles. For the rest it must be admitted that no uniform explanation is applicable to the groups of cases now being considered. The rapid development of the parotid swellings in early life and their frequent association with allergic symptoms are striking features, as is also the observation that in adults they are associated with emotional instability. As seen on X ray examination the changes in the ducts are alike in children and adults. Whether the primary obstruction is allergic, spasmodic, or catarrhal is uncertain, but once it has developed, it is followed by dilatation and sooner or later by infection. In childhood it may be found that the attacks cease with the elimination of certain articles of food from the diet, with the clearing-up of buccal infection or with simple massage of the parotid gland. In adults the same methods may be successful, but where organic changes are more advanced, slitting and dilatation of the duct, auriculo-temporal avulsion, and X ray treatment may all give better results.

PHYSIOLOGICAL CHANGES DURING PUBERTY

ALTHOUGH much statistical information is available concerning growth in the years of puberty, it is mostly based on the study of large groups of children at different age-periods. Thus it has been shown that about two years before puberty begins there is a slowing in vertical growth, followed by a rapid increase during several subsequent years, girls being taller than boys. The maximum increase in weight occurs slightly later than the maximum increase in height. Of the signs of puberty in girls, breast development is usually the first, and it is followed by rounding of the hips and the appearance of pubic and axillary hair, in that order. As a rule menstruation is the last, or almost the last, sign, becoming established when breast development is nearly complete.

Thinking in terms of the individual rather than the age-group Dr. Gustav Nylin¹ has made an intensive study of 12 girls in the four years during which the onset of puberty might be expected. They were inmates of the State Institute for the Blind at Tomleboda, and were most of them suffering from congenital eye defects, but they were chosen because their physical and psychical status was otherwise as nearly as possible normal. Conditions of examination were standardised. In all but one subject the maximum growth in height was found to correspond with the commencement of puberty, though the age at which this occurred varied considerably (from 9.8 years to 14 years, with an average of 11.8). The duration of this maximum height increase varied from 471 to 884 days, and in most cases breast development was complete when growth ceased. As breast development was found to be the first sign of puberty, there therefore appeared to be a close relationship between breast development and height increase. The thyroid also seemed to increase in size during the same period, but as the means of measuring its growth were not accurate, little emphasis can be laid on this impression. Nylin also found that the height-increase declined when menstruation began. The arteriovenous oxygen difference under standard conditions proved singularly constant during growth, from which he concludes that the blood flow is a

direct function of standard metabolism, since the latter was observed to increase considerably during the period of maximum growth. The pulse-rate fell throughout the period of study, and showed no signs of rising with the onset of puberty; but there was a rise in both systolic and diastolic blood pressure during the period of development. The vital capacity also increased during development, though its increase became manifest later than the other functional changes.

THE WILLIAM HARVEY MEMORIAL

WE wish to impress earnestly upon our readers the situation of the Harvey Memorial Fund instituted some time back with the object of rebuilding the fallen tower of Hempstead Church, Essex. Our readers have been kept informed of this movement and must sincerely

hope with us that it will soon come to a satisfactory conclusion, for the delay has been regretted by many, though strenuous efforts have so far failed to abbreviate it. The present position is that the work of restoration, which so far has been exceedingly well carried out, has proceeded, and about two-thirds of the structure has been restored; but the fund

is now exhausted and progress has ceased. The last third of the work, which includes the rehauling of the bells, remains to be dealt with, and a sum of approximately £2000 is yet required for the termination of the undertaking. Lord Horder has become chairman of the committee in the place of the late Sir John Rose Bradford, and all donations should be made payable to the Harvey Memorial Fund and sent to Dr. G. de Bec Turtle, Royal College of Physicians, Pall Mall East, London, S.W.1.

AN ANTISTREPTOCOCCAL AGENT

INTEREST has lately been aroused by the claims of German workers to have synthesised a chemotherapeutic compound efficient against streptococcal infections. This substance, which has been named Prontosil, when given either subcutaneously or by the mouth, protected mice against a lethal dose of streptococci injected into the peritoneal cavity. Whereas in untreated animals there were enormous numbers of cocci in the peritoneal exudate, in those treated with prontosil the organisms were few and mainly undergoing phagocytosis. The drug has no appreciable bactericidal action in vitro, and the mechanism by which it acts in the body was therefore obscure. At a discussion in London last autumn¹

¹ Physiology of the Circulation during Puberty. Acta Med. Scand., Suppl. lxxix., 1935, p. 77.

¹ THE LANCET, 1935, i., 840.

it emerged that English workers had been able to confirm the original claims only in part; a longer survival in experimentally treated mice was common, but ultimate recovery, so far from being the rule, was rather the exception. This difference was apparently attributable to the properties of the streptococci used, those in the favourable German experiments being derived directly from human sources, whereas in England the strains employed had been submitted to repeated mouse passage, with a consequent increase in virulence for mice. The still more recent findings of C. Levaditi and A. Vaisman,² who used non-passaged strains, indicate a striking therapeutic effect, but one to which there were exceptions in every series of animals; with whatever dosage, either of the drug or of culture, 100 per cent. survival was never obtained. These investigators also report experiments designed to ascertain how the drug acts. On the possibly inadequate ground that reticulo-endothelial "blockage" does not interfere with the therapeutic action of prontosil, they conclude that its effect is not secured by any sort of stimulation of the defence mechanism. On the other hand, they have come to the conclusion that it acts by preventing capsule-formation, and so rendering the streptococcus susceptible to phagocytosis. This plausible idea is supported only by the observation that the drug is ineffective when the inoculum consists of (capsulated) streptococci derived directly from the peritoneal cavity of another mouse. The hypothesis may very well be true, but it perhaps requires verification by other means. Meanwhile the therapeutic utility of this drug needs to be studied further in the clinical field, though the temptation to its indiscriminate employment should be resisted. Levaditi and Vaisman have shown by experiment that prontosil is without influence on a number of other bacterial and virus infections, and the original clinical results reported from Germany indicate that it is of value only in infection by *Streptococcus pyogenes*. Its use should evidently be restricted to cases of this infection.

RECONSTITUTION OF DURHAM UNIVERSITY

THE Commissioners appointed under the University of Durham Act, 1935, have drawn up a first draft of statutes for the reconstitution of Durham University. Under the new constitution the Newcastle College of Medicine and Armstrong College will cease to exist as separate corporations and be merged in University College, Newcastle-upon-Tyne. The council of University College will consist of the principal, the dean of medicine, six and twelve members to be appointed in the first instance by the existing councils of the College of Medicine and of Armstrong College respectively, six members to be appointed by the academic board of University College, four members by the Newcastle City Council, two members by the Northumberland County Council, two members by the house committee of the Royal Victoria Infirmary, one member by the committee of management of Newcastle-upon-Tyne Dental Hospital, two members representative of other associated hospitals, and, if the council so determine, two co-opted members. None of the members appointed by the existing council of the College of Medicine shall be full-time teachers and not more than two shall be part-time teachers in University College. The council will appoint a dean of medicine for a period not exceeding five years who shall be responsible—under the authority of the council, the academic board, and the

principal—for guiding the organisation and development of medical education and research and for maintaining close relations between University College and the associated hospitals. All matters relating to the organisation of medical education and research shall be referred in the first instance to a medical studies committee of the academic board. As soon as possible after the appointed day a temporary Newcastle council will be formed which will forthwith appoint a dean of medicine who shall thereupon become a member of the temporary council in place of the existing dean of the board of the faculty of medicine. As soon as this appointment has been made the temporary council will provisionally determine, without any report from the academic board, what holders of academic posts shall be members of this board. The Commissioners are ready to receive and consider any representations made to them before April 1st, 1936. Such representations should be sent to the secretary to the Commissioners, 3, Sanctuary Buildings, Great Smith-street, London, S.W. 1.

ACTION OF AMYL NITRITE

THE inhalation of amyl nitrite as a treatment for angina pectoris was introduced by Lauder Brunton in 1867. He tried it because he knew that venesection diminished the severity of the attacks of pain and it seemed to him that amyl nitrite, a drug already known to diminish vascular tension, should act similarly. The striking relief which it afforded was related by him to the fall of blood pressure produced by the drug with consequent relief to the heart. This, the most apparent explanation, received almost universal assent and is still held by some clinicians. It is only of recent years that the view has been attacked as inadequate, but the cumulative evidence against it as a complete explanation is now considerable.

Five years ago Lewis,¹ investigating a series of cases of angina pectoris associated with high blood pressure, found that amyl nitrite would often give relief without conspicuous change in the blood pressure, and concluded that the effects of the drug were not to be ascribed to simple lowering of the pressure but were "in part, if not in chief part, due to dilatation of the coronary vessels." Studies on the relationship of blood-pressure changes to the disappearance of pain in angina of effort after the inhalation of amyl nitrite have led to similar conclusions.² That amyl nitrite dilates the coronary vessels in animals is certain; but the fall in systemic blood pressure tends to reduce the flow of blood and this effect might well lead to a reduction in the total blood-flow through the coronary arteries. Actual measurements in the intact animal have given conflicting results, although the balance of evidence is in favour of an increase in the total blood-flow. The importance of further evidence in man is therefore apparent.

It is now widely believed that alterations in the electrocardiogram similar to those seen in coronary thrombosis may occur when there is a relative ischaemia of the cardiac muscle. Nitroglycerin has been shown by Scherf and Schnabel³ to prevent, or diminish the degree of, this alteration in attacks of angina pectoris, and Evans and Hoyle⁴ have demonstrated improvement in abnormal electrocardiograms after amyl nitrite. Nagl⁵ has recently

¹ Lewis, T.: *Heart*, 1931, xv., 305.

² Wayne, E. J., and Laplace, L. B.: *Clin. Sci.*, 1933, i., 103.

³ Scherf, D., and Schnabel, P.: *Klin. Woch.*, 1934, ii., 1397.

⁴ Evans, W., and Hoyle, C.: *THE LANCET*, 1933, i., 1109.

⁵ Nagl, F.: *Wien. klin. Woch.*, 1935, xlviii., 1543.

^{*} *Presse méd.*, Dec. 25th, 1935, p. 2095.

recorded simultaneously the effect of amyl nitrite on the electrocardiogram, arterial and venous blood pressures, and heart-rate of normal persons. Alterations in the T wave of the electrocardiogram were brought about which are interpreted as due to a temporary relative cardiac ischæmia. It is believed that this can be accounted for by the rise in the heart-rate which increases the work of the heart at the same time as the coronary flow is reduced by the fall in blood pressure. Nagl suggests, therefore, that amyl nitrite should not be used in cases of angina pectoris with a tendency to tachycardia. It is known that its inhalation may rarely increase the severity of anginal pain⁶ or even induce an attack,² and changes such as Nagl describes may well be the cause. But in practice it is impossible to foretell which patients will respond well and which badly to amyl nitrite and actual trial in an attack is the only test. It is worth noting that patients who suffer from the relatively mild pain of angina of effort usually prefer to take nitroglycerin, while amyl nitrite is best reserved for the long-lasting "spontaneous" attacks in which it gives the spectacular relief on which its reputation rests.

ETTORE MARCHIAFAVA

THE death of Prof. Marchiafava in Rome has been overshadowed by war, but the passing of so great a figure in international medicine should not be forgotten because he had outlived his contemporaries. Ettore Marchiafava was born in Rome on Jan. 3rd, 1847, and he died there on Oct. 25th, 1935. He took his degree in medicine in 1871, was nominated next year assistant in the university department of pathological anatomy, and succeeded to the chair in 1883 when Tommasi-Crudeli was transferred to the chair of hygiene. During his 40 years as professor of pathological anatomy Marchiafava made many important contributions to medical knowledge. This was a time of renaissance in Italian medicine, in which he bore a distinguished part. He was a great teacher; his lectures on patho-

logical anatomy made the dead live again to his hearers as he recalled the history, the symptoms and physical signs, and summed up their relation to post-mortem findings. But outside Italy Marchiafava's fame is based upon his observations on malaria. As early as 1879 he maintained that melanin was derived from the destruction of the hæmoglobin of the red corpuscles, and he went on to interpret correctly the early stages of development of the malarial parasite. With Celli he demonstrated the development of the parasite in the red corpuscle, the amœboid movement, and the production of melanin. In 1889 he and Bignami discovered the parasite of æstivo-autumnal or subtertian fever, and in 1892 they described the character of the pernicious forms. He was also able to differentiate the quartan from the benign tertian parasite. Marchiafava's interest in pathology never

ceased, and in his ninth decade he was still to be found at work in the Institute of Pathological Anatomy.

RED CELL SEDIMENTATION IN HEART DISEASE

THE value of the erythrocyte sedimentation-rate as an indication of active disease has been demonstrated in rheumatic carditis, and also in syphilitic aortitis, thyrotoxicosis, and hypertensive heart disease. In the January issue of the *Quarterly Journal of Medicine* Paul Wood gives the results of sedimentation tests done on 164 cases of all types of heart disease and heart failure, excluding cases with any form of intercurrent infection or with a secondary anæmia as shown by a red cell count of under 4 million or a hæmoglobin under 70 per cent. As controls he has used 19 patients with cardiac neuroses. He finds that congestive heart failure retards the sedimentation-rate regardless of the cardiac pathology and therefore masks evidence of active disease. Increased sedimentation-rates are found in active rheumatic heart disease, myocardial infarction, and syphilitic aortitis; the result in this last condition may help in the distinction between an aortic valvular disease due to syphilis, rheumatism, or athero-sclerosis. Again, the sedimentation-rate may enable one to distinguish between coronary thrombosis, angina of rest, and angina of effort, since in cases of coronary thrombosis the rate is not immediately increased, but after a day or two increases steadily to a maximum, till about the end of the third week, after which it slowly returns to normal. Angina of effort, on the other hand, shows a normal sedimentation-rate, and angina of rest, in the absence of syphilitic aortitis, gives a slightly to moderately increased rate which does not change materially from week to week.

THE ENDOCRINE ORGANS AND INSANITY

"We believe that it cannot be successfully denied that the *corpus* of present day psychiatric literature conveys, and is intended to convey, the idea that the endocrine pattern is a significant and important causal factor in the etiology of those abnormalities of behavior that are collectively subsumed under the term 'insanity.' But where is there precise *proof*, in the truly scientific sense, that this is so?"

HAVING put this question to themselves, and finding no satisfactory answer, Raymond Pearl, Marjorie Gooch, and Walter Freeman set about the task of seeing whether a statistical study of the weights of the endocrine organs in a group of the insane would provide any information from which conclusions could be drawn. Their study,¹ most carefully and laboriously carried out, deals with 1307 insane persons dying in hospital and examined *post mortem* by Freeman. Each individual was placed, according to the preponderance of clinical evidence, into one of four broad groups—namely, cycloids, paranoids, schizoids, and epileptoids. This material, as the authors point out, has serious limitations; it relates wholly to a mentally diseased population, and standards of comparison from normal persons can be taken only from the very heterogeneous materials available in the literature. Secondly, the progress of the patient to death may well have changed the biologically normal weight relations of the parts. Imperfect as the data are, they should, however, be capable of revealing any pronounced differences between what the authors term the endocrine pattern of the psychiatric disease types.

⁶ Wood, F. C., and Wolferth, C. C.: *Arch. Internal Med.*, 1931, xlvii., 339.

¹ *Human Biology*, 1935, vii., 350 and 555.

In fact the analysis shows no striking or orderly difference in the weights of the various organs in the four groups. If, for instance, aberrations of thyroid structure and function are significant factors in the ætiology of different types of psychoses, this fact is not reflected in any definite manner in the weight of the organ, so far as the present data indicate. On the other hand, the quantitative pattern of the endocrine system as a whole, as indicated by organ weights, does appear to differ between the insane and the most reliable "norms" that the authors have been able to discover. This difference concerns not so much the total mass of all the endocrine organs taken together as a whole, in proportion to body size, but the *pattern* of the system—the proportionate quantitative contribution of the several organs to the total. Judging by this comparison, the insane are deficient relatively in thyroid tissue but over-supplied relatively with parathyroid, thymic, and adrenal tissue. They show only a generally small and probably insignificant relative excess of pituitary and pineal tissue and a small relative deficiency of testicular or ovarian tissue.

The authors with becoming caution conclude, therefore, from their elaborate study that the pattern of the endocrine system as a whole *may* really differ significantly between the mentally diseased and the not-mentally diseased, but to prove this will require more evidence, and evidence of a different character, than they have been able to present. Until that evidence is available they suggest that vague generalisations about the importance of the endocrine glands in insanity are premature.

A CAUSE OF ULCERATIVE COLITIS ?

CHRONIC ulcerative colitis is sometimes regarded as a sequel to bacillary dysentery and sometimes improves under treatment with antidysenteric serum. Bagen attributes it to a specific diplo-streptococcus; others have put forward the claims of certain anaerobic bacteria. None of its "causes," however, has yet been generally accepted and attention must therefore be paid to the evidence put forward by Dack and his fellow-workers¹ in Chicago. Believing that no satisfactory growth of a delicate and deep-seated organism is likely to be obtained in ordinary cultures of fæces—or indeed from scrapings of ulcers seen directly with proctoscope or sigmoidoscope where the contents of the upper bowel are continually pouring over the ulcerated area—they have investigated 3 cases of chronic ulcerative colitis in which symptoms and radiographic and proctoscopic examinations were characteristic of the severe form of the disease, and in which the affected colon had been completely isolated following an end ileostomy. Numerous observations of these cases led to the recovery from the colon of Gram-negative pleomorphic non-sporulating rods extremely sensitive to oxygen and difficult to subculture. The same organism was isolated by appropriate methods from the non-isolated colon in 7 out of 12 additional cases of non-specific chronic ulcerative colitis and in 2 cases of specific (amœbic) ulcerative colitis. Complement-fixing antibodies were found in the serum of 14 out of 16 cases of typical chronic ulcerative colitis, but in only 3 of 16 control patients. In several cases complete fixation was obtained with a serum dilution of 1 in 10. The organism in question seems to resemble very closely the bovine *Bacillus*

necrophorus which produces severe septic processes in a number of domestic animals. This organism may invade any tissue and produces various necrotic foci—e.g., calf-diphtheria, necrotic ulcers of the intestine in hog-cholera, metastatic necrosis of liver and lungs of cattle and swine, and necrotic stomatitis of calves, lambs, and pigs.

MILK BY FOUR DIFFERENT NAMES

FROM April 1st of this year there will be four grades of milk instead of the five on sale at present. The draft Milk (Special Designations) Order, 1936, does not employ exactly the nomenclature forecast in our leading article of July 6th last, but the scheme is substantially the same, with its advantages and disadvantages. In future there will be two grades of fresh milk, called Tuberculin-tested and Accredited; also two grades which have been treated by heat, called Pasteurised and Certified (Pasteurised). The last-mentioned is tuberculin-tested milk which has been pasteurised, and it will therefore be the cleanest and safest of the four grades, having a bacterial content of not more than 30,000 bacteria per c.cm. (compared with 100,000 in pasteurised). The present top grade, Certified, which is bottled on the farm and contains no more than 30,000 organisms, is abolished. Tuberculin-tested and accredited milks will closely resemble the present Grade A (T.T.) and Grade A respectively; but after the end of this year the requirement that they shall contain no more than 200,000 bacteria per c.cm. before delivery to the consumer will be replaced by a methylene-blue reduction test. Everyone will be glad that the name "Grade A" should give way to a more non-committal description, and it is an advantage that the "accredited" herds should be inspected quarterly instead of every six months. But whatever its name, this type of milk cannot—as we said in July—be recommended by the medical profession for consumption in the raw state.

Under the new Order the Ministry of Health will no longer grant licences to producers of tuberculin-tested milks. All the licences will henceforward be issued by local authorities.

OWING to the death of King GEORGE it has been decided not to hold the Hunterian festival dinner of the Royal College of Surgeons on Feb. 14th, but the Hunterian oration will be delivered at 4 P.M. on that day by Mr. C. H. Fagge as arranged. The ball of the St. George's Hospital medical school on Feb. 19th has been cancelled, and the dinner of the Royal Society of Medicine on the same day has been postponed. Prof. Edward Mellanby's lecture, on Jan. 31st to the Royal Institution, on Recent Advances in the Treatment of Disease has also been postponed.

INDEX TO "THE LANCET," Vol. II., 1935

THE Index and Title-page to Vol. II., 1935, which was completed with the issue of Dec. 28th, is now ready. A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXVI.—PROGNOSIS IN ASTHMA

It is generally held that asthma does not appear unless there is a hereditary predisposition, and as this predisposition is inherent and permanent it is impossible to speak of a cure for asthma. On the other hand, we have reason to believe from the study of pedigrees and from the results of skin tests on apparently normal individuals that the asthmatic tendency may remain latent throughout life, and we know that many patients lose their asthma for long periods of time.

Little is known about the factors which determine the latency or manifestation of asthma. Some physicians of experience do not share the prevalent enthusiasm over modern methods of treatment, and believe that we are no better able to control the disease than were physicians of a generation ago, though we are better equipped than they to relieve its symptoms. Asthma is a variable illness, and while we must often sympathise with the patient in his relapses, we can also congratulate him on his remissions. It is understandable that these remissions should be attributed to the treatment, rather than to that waywardness of the disease which we consider responsible for the relapses, and every therapeutic novelty is for a time regarded as a cure for asthma—vaccines, endocrines, allergens, X rays and irradiation, ketogenic diet, gold, liver, artificial fever, and sympathectomy. Attacks of asthma, like attacks of peptic ulceration or acute rheumatism, tend to recover spontaneously, and of patients seeking medical advice for asthma some 50 per cent. may be expected to improve without specific treatment. With few exceptions no treatment precludes the likelihood of relapse in a few months or years, and though it is possible to distinguish those who are likely to do well from those who are likely to do badly, it is rarely wise to predict complete cessation of the paroxysms. For all this, I believe that the outlook for the asthmatic patient to-day is better than it was thirty years ago.

In what follows I shall assume the orthodox treatment of asthma. The paroxysms are relieved by antispasmodics such as adrenaline and ephedrine. Between the attacks attention is paid to the hygiene of life, the avoidance of overloading of the stomach or colon, the minimisation of contact with animal and vegetable dusts. Psychological stimuli are removed and respiratory exercises are carried out regularly. Septic foci and nasal abnormalities are treated with the utmost conservatism. When there is bronchitis an autogenous vaccine from the sputum is used, and if the patient is clearly sensitive to common inhalants such as pollen or orris root the attempt is made to desensitise him.

The questions that arise in prognosis are (a) risk of death in a paroxysm; (b) prospect of immediate improvement; (c) prospect of permanent recovery; (d) effect of the disease on the general health and duration of life.

Death in or following a Paroxysm.—It is sometimes suggested that asthma is more annoying than dangerous, and that it has little influence on the duration of life. It is true that death during a paroxysm is unusual. It is nevertheless not so unusual as is taught, and whenever a patient passes into the status asthmaticus or has persistent dyspnoea for more than one or

two days the risk of sudden death should be seriously considered. Experience of a large clinic at which several hundred patients are in regular attendance suggests that one or two of these patients may be expected to die of asthma every year. Death may result from the immediate effects of the paroxysm, from heart failure, or from pneumonia. I believe that pneumonia is usually initiated by patchy or more massive collapse of the lungs induced by excessive secretion of mucus and bronchospasm, and it may be followed by pleurisy and empyema. A rarer sequel of the paroxysm is spontaneous pneumothorax, which is usually more alarming than dangerous. I have also seen cerebral hæmorrhage in a young woman.

Prospects of Immediate Improvement.—With modern treatment about 20 per cent. of patients are completely relieved of their asthma for some years; between 15 and 20 per cent. are absolutely resistant to treatment, while the remainder are more or less improved though still subject to attacks. In other words, between 66 and 75 per cent. of cases are significantly improved. Failure to improve may be due to incomplete investigation and treatment, or to ignorance and lack of coöperation on the part of the patient. The patient may know the cause of his asthma but is unable to avoid it and desensitisation proves unsuccessful. The ability to spend one's childhood at a public school on the south coast rather than in an overcrowded tenement in Hoxton, to winter in Switzerland, or to undergo a long and expensive course of desensitisation, is naturally an important element in prognosis. Favourable features are early age of the patient, brief duration of the asthma, and infrequent attacks. The popular belief that children "grow out" of asthma probably exaggerates the frequency of spontaneous recovery and should not be allowed to encourage neglect of treatment. A seasonal incidence and sensitisation to a single inhalant such as pollen, to which the patient can be specifically desensitised, are of good prognostic omen. Allergic complications such as hay-fever, rhinorrhœa, eczema, and migraine are of no moment, and, indeed, in so far as they stress the importance of protein hypersensitiveness, are of good augury. Nasal disease, respiratory complications (such as bronchitis, emphysema, and pulmonary fibrosis), and hyperpiesia mitigate strongly against lasting improvement. The chronic nasal patient, shorn of turbinates, wheezing and whistling through his antrostomies, is as big a bugbear to the physician as is the chronic abdominal patient, and he is as little amenable to treatment. As already indicated, the chances of improvement are inversely proportional to the age, and while the duration of the asthma is less significant than the age of the patient, it is unusual for a patient who has had asthma for more than 20 years to gain real freedom from the disease.

The Prospect of Permanent Recovery.—What happens to patients who are for a time completely relieved of their asthma? Unfortunately many of them relapse, and within five years nearly half of them are having asthma again. It is probable that the longer the remission the smaller the likelihood of relapse, but it is quite common for patients to relapse after being free for ten or more years. Remissions of this kind occur most frequently between the ages of 15 and 30,

and it is not unusual for adults coming for treatment to give a history of asthma in childhood which disappeared at puberty and has only reappeared after many years. In such cases it is usually a new and different stimulus which is evoking the asthma—in Rackemann's simile the gun remains loaded and a new trigger is firing the attack. Once more improvement should follow appropriate treatment, an improvement which in chastened mood we shall now describe as relief rather than cure.

Effect of Disease on General Health and Duration of Life.—The risk to life is greater in patients over 40, more especially when the asthma did not develop till adult life; in those whose attacks are frequent and difficult to relieve by symptomatic remedies; and in cases accompanied by atheroma, hyperpiesia, or emphysema. The family history is more often negative and protein hypersensitiveness is more often absent in fatal cases than in the average asthmatic. On the other hand, extreme protein hypersensitiveness is not unduly dangerous except in so far as acute anaphylaxis may result from the parenteral introduction of the protein in skin testing or in attempted desensitisation. In patients under 40 with mild and occasional asthma the mortality is probably not more than 25 per cent. above the standard figures. In patients over 40 with frequent and severe paroxysms the mortality is two or three

times the standard value, the excess of deaths being due to heart disease and pneumonia.

Apart from respiratory and cardiovascular complications asthmatics are a healthy race, perhaps less liable than their fellows to infectious illnesses. They are bad subjects for operation or for acute respiratory disease, but have the compensation that an operation or a febrile illness is often followed by a relatively long period of freedom from asthma. The distress induced by a hearty meal induces many of them to maintain their nutrition at a subnormal level, but this doubtless has its advantages as well as its drawbacks. They are intelligent and courageous, and while psychological factors play an important part in their illness it is unwise to regard an asthmatic as neurotic in the derogatory sense or he will confute you by dying in an attack. If the physician cannot cure the malady the patient can nevertheless learn to manage it and live with it, and he should be encouraged to live as full a life as possible. Occupations which entail arduous physical exertion or exposure to dust are unsuitable, but with these exceptions the asthmatic should be encouraged to look forward to a career on an equal footing with his fellows.

L. J. WITTS, M.D., F.R.C.P.,

Professor of Medicine in the University of London at St. Bartholomew's Hospital Medical School.

SPECIAL ARTICLES

MENTAL HEALTH

TROUBLES OF ADULTS AND CHILDREN

THE fourth biennial conference of the National Council for Mental Hygiene was held at the Central Hall, Westminster, from Jan. 23rd to 25th. At the opening session the chair was taken by Mr. W. F. Roch, vice-president, and a discussion on Mental Hygiene and International Relations was opened by Lord ALLEN of HURTWOOD, who said he believed that the psychological factor would increasingly determine the question of war or peace. Almost for the first time in history the exercise of imaginative will-power could now give the victory to peace, notwithstanding the causes of war that still remained. There was now no physical reason why anyone in any part of the world should be hungry, ill-clad, or ill-housed, or why nations should fight for their livelihood. There was now a mechanism, in the League of Nations, whereby men could make effective over the world of nature that mastery which science had placed in their hands. Men's minds, however, seemed to be still inadequate and the problem was one deserving the consideration of those interested in mental hygiene. Mental adjustment and control were essential to counterbalance the accumulated fund of tradition and behaviour which caused every nation to work off its unsocial passions on its neighbours. The evils of the Treaty of Versailles might have been due very largely to life in an ill-ventilated nursery ruled over by a tired nurse and visited by a preoccupied father and a too-loving mother. The citizen must cease to make his children in his own image. Dr. WILLIAM BROWN read the paper published on p. 290, and a brief discussion followed.

At the first session on Friday morning the chair was taken by Dr. Arthur MacNalty, and the subject of discussion was the Organisation and Correlation of Mental Health Services in Local Areas. The

opening speakers were Prof. R. M. F. Picken, Miss Evelyn Fox, and Dr. T. S. Good. In the afternoon, under the chairmanship of Mrs. E. M. Hubback, Dr. Helen Boyle, Mrs. Neville Rolfe, and Mr. Claud Mullins opened a discussion on Problems of Marriage and the Establishment of Courts of Domestic Relations. Eloquent appeals were made by magistrates and doctors alike for the establishment of special courts, imbued with the atmosphere of the consulting-room, to try to prevent the breaking-up of marriages which might be saved by modern psychological methods and the application of sympathy and common sense. Several speakers also urged extension of the divorce law for cases where there was no possibility of successful treatment.

In the evening the Bishop of Southwark took the chair, and a discussion on the Priest and the Doctor in the Treatment of Nervous and Mental Disorders was opened by Dr. H. CRICHTON-MILLER. Nervous and mental disorders, he said, did not arise from simple causes, and it was in the field of multiple causation that the coöperation of priest and doctor was most often justified. It was essential to guard against the facile acceptance of a single explanation which, more than anything, led to partial and ineffective treatment. The adjustment of a personality to, for example, a persistent neuralgic pain should be the concern both of doctor and priest. The three great sources of maladjustment were fear, guilt, and inferiority, and in each of these, and particularly in the second, the priest had a part to play. The problem for discussion was: "How far does equanimity count in promoting and maintaining health, and what measure of equanimity can be secured by the representative of organised religion?" Just as science was broader than the practice of medicine, so religion was broader than the function of the priest.

Canon T. W. PYM expressed the difficulty of the priest who was certain that his penitent was nervously ill when the general practitioner called it overwork

or indigestion and dismissed the matter. The temptation to unprofessional psychiatry was very great. Even when the patient was put in the hands of the right doctor the priest's business was by no means over. For the rebuilding of the religious section of the mind after the psycho-analytic breaking-down the religious expert was needed. Probably very much could be done by ministers of religion to prevent the onset of a nervous or mental disease if only the clergy could obtain some reliable instruction.

Mr. Z. F. WILLIS regretted a tendency to water down Christian essentials in order to establish a respectable concordat with science. He outlined the contributions which the priest could make to psychotherapy, emphasising his value in convalescence.

On Saturday the subject of the three sessions was

Education for Living

In the morning the period before the age of eight was discussed, in the afternoon that from eight to fourteen, and in the evening that from fourteen onwards. The chair at the first session was taken by the Rev. A. W. Harrison.

THE NURSERY

Dr. R. G. GORDON outlined the problems of the infant, and the seeds that might be sown in the early months of life. The relationship of the child to the parents should be an equilateral triangle; divided loyalties were reflected in the growing child by a sense of bewilderment or an attempt to play off one parent against the other. Recent work had thrown a good deal of light on eidetic imagery: an imagery so vivid that it could not be distinguished from reality. About 50 per cent. of children experienced it, but it always faded soon after puberty. A child might be accused of lying when he was really merely describing such images, and if they were really alarming they might have a serious effect on the child's development. Frightening experiences, whether real or imaginary, produced a feeling of insecurity in respect of his environment, while sexual experiences or images produced a sense of guilt or insecurity.

Dr. MARIA MONTESSORI described the process of the child's growth and said that all living creatures in the early stages went through sensitive periods. The young caterpillar found the tender shoots at the tip of the branch as the result of his extreme sensitivity to light, and lost that sensitivity as soon as he was capable of absorbing other nourishment. By means of temporary sensibility of this kind each characteristic was fixed and stabilised. The child's purpose was totally different from that of the adult. He did not scrub a table to get it clean but to scrub until he had mastered scrubbing. The child who had been thwarted in one of his sensitive periods had lost for ever that particular chance of natural growth. Such thwarting might provoke violent reactions with no apparent cause. It was therefore essential to investigate the causes of naughtiness and capricious behaviour. The adult knew the child as he was in disease but had no knowledge of the healthy child because, like all other undiscovered forces of the universe, he was outside the adult's experience.

Miss J. A. CALLARD (vice-chairman, Welsh committee, National Union of Teachers) said there was no reason why the nursery and infant stages should not be regarded as a whole, and the primary consideration at this period was the incessant care for the physical well-being of the child, and regard for the cultivation of desirable habit and deportment. The more formal aspects of instruction would not be

emphasised, but continuous progress would be made in knowledge and expression by methods which invoked in aid of education the pleasurable activities natural to children. As a result of modern training, teachers were both qualified and anxious to undertake this work. There was a crying need for more and better provision for the younger children of this country. The pre-school child had suffered hitherto an avoidable neglect. The open-air principle was particularly desirable for the younger children, and a garden was invaluable. Miss Callard pleaded for the use of the opportunities already available; hundreds of classrooms in infant schools were unoccupied, and their adaptation would be less costly than building nursery schools. There was no reason for the creation of a gulf between schools for those under five and for those over five, and the amenities of a nursery school should be accessible after that age. Regular and nutritious meals were essential, as were also training in hygiene and cleanliness, and provision of bathing facilities and stretcher beds for the afternoon rest. There was a need for unification of administrative control.

In the afternoon the chair was taken by Dr. J. A. Glover, and Dr. EMANUEL MILLER spoke on

MOULDING THE MIND: EIGHT TO FOURTEEN

He looked with suspicion, he said, on any efforts to mould the mind, for the phrase implied preconceived ideas as to shape and a ready-made design for living. The major conflicts of life were faced and dealt with in the first five years, neurosis and character formation being the resultants; intelligence alone remained to develop. The ability to exercise curiosity, to make emotional contacts with schoolmates and teachers, depended on the degree of emotional freedom left after the years of early struggle. Before teachers set to work on the child between eight and fourteen they ought to be provided with such knowledge of his childhood as was put into the hands of physicians by the social worker of a child guidance clinic. It must be ascertained whether the child was tenderly mother-fixed or terrified by parental authority; whether he had latent anxiety or an obsessional disposition. The attempt to mould the mind must be made with knowledge of the material presented. The intellectual capacity and character must be studied and estimated. Special handling would be called for if there were lack of capacity to play in group games, inability to ask questions or excessive questioning, lack of curiosity about manual operations, excessive "goodness," indifference and shyness in social contacts, attitudes of renunciation, or repeated physical incapacity with trivial physical signs or absence of organic disease. Moulding should be designed to remove anxiety or obsession by active treatment, to obviate frustration by love, to afford outlets for aggression in the play group, to condone vulgarity, to organise the "gang spirit" by suitable group activities, to accept sympathetically the tendency to inverted sex interests by preparing for heterosexual enlightenment at puberty, to correct physical anomalies before puberty, and to cultivate manual and artistic aptitudes.

Miss M. WITHERS (headmistress, Dawson Junior Girls' School, Barking) said that nowadays children were not educated for their work but for their leisure. If they were to get the most out of life every side of their nature must have an opportunity to develop; there must be an inner harmony and balance not easily upset by the buffets of life. The school must see that each child was given ample opportunity for

self-expression. This, with the younger ones, came most naturally through painting, acting and rhythmic movement, but if these were to be continued successfully with older girls there must be a carefully planned progressive scheme. The objects of education could be helpfully discussed with nine- to ten-year-olds. Coöperation between home and school was very important, as parents were apt to be concerned primarily with the means of securing a job. When the early forms of self-expression ceased to interest, some kind of craft work was most likely to appeal. Nature study and elementary science were always attractive, and children took infinite delight in growing plants, animals, and the vagaries of the weather. The humanities were the most important of all subjects. Literature gave immense pleasure to children. Children should leave school with the belief that they were entering on a great heritage and that the infinite resources of knowledge were only waiting to be explored.

Miss F. HAWTREY (principal, Avery Hill Training College) said that her students were taught to aim at directing activities rather than at moulding the mind. It was easier to change theory than practice. Modern theory was enlightened, but the average class still contained 40-60 children, wedged in heavy dual desks between high windows, and formative experiences were almost impossible to attain. The child owned nothing but his own copybook; the figures he modelled must return to the common lump, and the well-thumbed text-books must go back to the school cupboard. Schoolrooms were dark and stuffy, and cold water alone ran into the small stained basins. The asphalt playground was as hideous as a prison yard. Moreover, there were still many teachers who had learned in a hard school and felt that they must teach in a hard school. Amidst these surroundings "education for living" must be practised. One of the most serious and insidious threats to freedom arose from the scholarship examination. A little girl of 5½ was said to have observed, "I shall have to get a move on; I have only 4½ more years to get my scholarship." Yet many thousands of teachers were now giving their lives to put the new theories into practice. Bare classrooms were filled with flowers. Flower-beds were made in playgrounds with soil and manure brought in paper bags. Opportunities were found for music, dancing, dramatic work, and painting. The Hadow recommendations would not become effective until suitable schools were provided; the reform of school buildings was an urgent question for education. Schools ought to be beautiful. Prof. Burt had said that the ideal school should be a wilderness playground with a shelter somewhere in it. Nowadays a child's natural exclamation on seeing a gull was, "Look, Mummy, it flies like an aeroplane!" The sum of one penny a day per child would be enough to ensure the future and enable the young "to draw good into themselves from all their surroundings."

THE FINISHED PRODUCT

The evening discussion on the adolescent was conducted under the chairmanship of Mr. Basil Yeaxlee. Mr. R. E. ROPER said that the educational ladder at this age was supposed to lead to higher things, but the trouble about a ladder was that so few people could use it at one time. The post-war increase which had filled the schools was now swelling the ranks of young labour. Into this mad medley were thrown those who had completed secondary school or university courses, slaving for a certificate or degree which would give a better chance of

employment. The anxiety and competition inseparable from adult life to-day cast their shadows over the 8-14 group with a ruinous pre-selection from which infant schools were not wholly free. There was an increase in young adult tuberculosis and a rise also in the number of those certified as mentally defective, and in suicides and attempted suicides. The present chaos could be reduced to some order by raising the school-leaving age, with maintenance where necessary, by extending continued education and by improving school premises. The size of the classes must be reduced and education must be thought of in terms of the individual. All examinations before the last year should be abolished, and even this one should be combined with records of school life as a whole. Above all, anxiety must be removed from education. "Finished" too often meant "done for"; the educationist must see that it meant "perfect," so far as age permitted.

Miss G. HADOW (principal of the Society of Oxford Home-Students) declared that most of the girls who came to her from secondary schools were healthy minded and wholesome, but the exception always attracted the greater interest. There was no doubt that some girls felt the responsibility of being a prefect as something that was a strain, and reacted from it during their first year at college. A break between school and university would nearly always be beneficial, as for many people the change was too abrupt. This especially applied to day-girls, who were often miserably homesick when they first went to college. The difficulties in the way of this break were the loss to the school of a girl at a time when she was most useful, and the necessity of the scholarship. It would be a very good thing if the idea could be disposed of that university education was a mark of special distinction at which every intelligent girl should aim. The present tendency was to judge the worth of a school by the number of girls it sent to a university, and girls who were not really suitable were pushed into college life. Very few entrance candidates showed much evidence of thinking for themselves, and the general attack on and defence of all kinds of opinions encountered at the university were often a shock. One of the weaknesses in school training was lack of precision in thought and expression; there was no evidence of the present generation thinking more clearly or accurately than the last. Its interests, however, were world-wide, and the tone of Oxford was one of conscious responsibility as citizens. Young Oxford passionately desired to be just. The present generation had got over the tendency of the immediate post-war group to kick against every kind of restriction. Like every generation, they wanted experiment and adventure, but their sense of justice and citizenship stood out conspicuously.

Mr. G. A. LYWARD (director, The Clinic and School, Finchden Manor School, Tenterden) said that he proposed to speak about honesty but to call it teachability. He quoted a question presented to him recently by a group of 20 neurotic adolescents after a discussion on coöperation. "Doesn't it look," they said, "as if clear thinking is feeling?" There were two kinds of stealing in adult life: the open and direct, or the indirect dishonest way of, for example, telegraphist's cramp. Both types of thieving were apt to end in confinement: though one place of detention was called a prison and the other was not, both were but external indications of an already imprisoned condition. All of us started life in a prison of some kind, and those who had the care of us

from 0 to 14 helped us to pay off the original debt and enabled us to live like the kings of old, "of his own." Those who were neglected or indulged and so robbed of this capacity remained credit-seekers. They were not the joy-finders, for joy was born of pleasure and pain, success and failure. It did not come to those who lived to please mother. An adult might be defined as a person that had at last grown able to rely upon himself as teachable. The physically grown-up who were not adults in this sense were still fundamentalists and never clear thinkers. The unteachable group included those who were already neurotic at 14. They held on tenaciously to a variety of ideas and ideals which were dangerously different from what they could afford to feel about the same issues. They did not feel personally at all, having as it were numbed themselves against the pain of loss and failure. They were easy prey to the too good and the too bad around them.

The aim of the educationist must be to render teachable, to wean the babe from his delinquency, waywardness, or indebtedness, so that he could concentrate and consecrate body and mind to an ordered life and service which were increasingly free. From 14 onwards was the time when it was necessary to do what the baby could not do: to make distinctions. The whole question involved in differences had to be faced. Before 14 it was comparatively easy to shut one's eyes to differences. At 14 the thinking apparatus might work in either of two opposite ways: it could clarify or confuse and camouflage. It was a shame that the world so often fell to pieces for the child of 14. It would be a sign of grace if the public schools would open their eyes to the fact that a system in many ways desirable for the 14-year-old was not suited to the hundreds who went to public schools still at an emotional age of 3. The number of such would be considerably reduced if more preparatory schoolmasters would appreciate the value of real chaos plus security. Thousands of 14-year-olds were not at public schools but were leaving State schools for all kinds of occupations. At that age they were not so much teachable as suggestible, and when they could not stomach what they met they might either identify themselves with it so that they lost their play and became industrial personalities, or let themselves become machines in work and compensate by an equally mechanical pleasure-world.

All education should be organised with an eye to the danger and ease with which escape from life could be made. There should be more bureaux where adolescents could be saved if possible from drifting into jobs on motives which could not long remain adequate. Ways of escape from growing up might be found in all sorts of culture and even in the scholarship system. Curing was not so effective when the healer did not relate the child's emotional problems to his classroom difficulties, and the true task of the teacher everywhere was to discover the child through his classroom difficulties and vice versa. There were still many teachers as blind as their pupils to the fact that all subjects and all work revealed mind at its creative task of carrying life from the vine to the branches. The unphilosophical teacher was a dangerous teacher, afraid to teach to the feeling because he himself confused "feeling" with "feelings." Children must be so taught that they would expect to find differences within sameness, for in that lay their hope of ultimately finding a unity in the differences. Only such a person was truly honest, truly loving, truly human, and teachable.

MEDICINE AND THE LAW

Respite of Death Sentence after Medical Inquiry

REFERENCE was made under this heading last week to the case of *R. v. Mortimer*, the man who was found guilty of murder in that he had deliberately driven a motor-car so as to run down a woman on her bicycle. There had been a question of the admissibility of evidence of his having similarly driven a car at other women both before and after this particular occasion. The comment was ventured that the defence, having relied on disputing the identity of the motorist, had been debarred from raising the question of insanity. The case established conduct so abnormal that it seemed inevitable that the Home Office would intervene before execution of the sentence.

Hardly had this comment been made before it was officially announced that the Home Secretary, acting under Section 2 of the Criminal Lunatics Act, 1884, had caused a medical inquiry into Mortimer's state of mind, and, after considering the medical experts' report, had recommended the respite of the capital sentence. Thus Mortimer's punishment is nominally commuted to penal servitude for life, and he goes to a convict prison where he will be kept under medical observation. We see therefore how narrow the scope of a criminal trial must necessarily be. Mortimer's conduct was that of a madman, but the issue of his mental state (which must have been the dominant question for the average spectator at the trial) was excluded. In other words, the case illustrates the two different standards which the community applies at different stages of the administration of justice. To the judge and the jury at Winchester assizes, and to the Court of Criminal Appeal, Mortimer was 100 per cent. sane and was fit to be hanged; to the authority which carries out his sentence Mortimer was partially insane and unfit for the death penalty. Naturally the assize court was concerned with his mental state at the date of the offence, whereas the Home Office was concerned with it at the date of the medical examination after the trial; but it will probably not be asserted that Mortimer suddenly changed from sanity to insanity between the two dates. The difference of standard is clear. The criminal court would be concerned with the question whether the prisoner, at the time of the offence, was insane within the limits of the doctrine of criminal responsibility as laid down by the courts. The Home Office is concerned with the question of his insanity under the ordinary law whereby a man can be certified and removed to an asylum. The distinction was brought out by the Home Secretary in the House of Commons after Ronald True's case (Commons Debates, June, 1922, p. 210), and was carefully examined by the Atkin Committee on Insanity and Crime (see the report, Cmd. 2005, published in 1923); possible change in the law and practice of cases falling within Section 2 (4) of the Criminal Lunatics Act, 1884, was one of the questions specifically referred to the committee. There is an ancient legal repugnance to the execution of an insane criminal. Sir Edward Coke, for instance, observed that such a course would be "a miserable spectacle, both against law and of extreme inhumanity and cruelty, and can be no example to others." The repugnance is due to the two ideas that a man of unsound mind is barred from submitting some possible point in stay of execution, and that it is not Christian charity to send him into another world

when he is not of capacity to fit himself to meet his Maker.

Use of Inquest Depositions in Criminal Court

When a man and woman were charged, at Clerkenwell Police-court last week, with the murder of a woman who died after an alleged illegal operation, the prosecution put in the depositions taken at the inquest. Counsel for the male defendant objected, on the ground that, though the man had been called upon to give evidence on three occasions before the coroner, he had never been cautioned that what he said might be used in evidence against him. Counsel suggested that the accused had been severely cross-examined at the inquest which had in effect developed into an inquiry whether the witness had not been an accessory to the alleged illegal operation. Asked by the magistrate if he asserted that the inquest had been improperly conducted, counsel replied that he did not go quite so far, but he did complain that something not proper was done. The prosecution contended that it had been clearly laid down that the question of being cautioned was a point to be taken by the witness and was not for the coroner. This was possibly a reference to a case in which THE LANCET has a special interest, *Wakley v. Cooke*, where the judges supported the view that people should be allowed to make any statement they desire at an inquest and, while not bound to incriminate themselves, must look after their own interests in giving evidence. The prosecution at the Clerkenwell Police-court further referred to a dictum of Mr. Justice Swift that cases of alleged illegal operation would never be brought into court at all if witnesses were cautioned. The magistrate allowed the inquest depositions to be admitted. This course seems clear in view of Section 5 (3) of the Coroners Act, 1887, though doubts have arisen in the past over admitting a witness's deposition taken before a coroner where the accused was not present at the inquest.

Inquest on Death in Nottingham Nursing-home

The Nottingham inquest on Miss Ada Louisa Baguley, a cripple aged 50, who died in an unregistered nursing-home carried on by Nurse Waddingham and Mr. R. J. Sullivan, stands adjourned in view of the ill-health of an important witness. Pending its completion, it is not possible to comment on the important elements of the case and the light it throws on the safety of the system of certification before cremation. Reference may however be made to a point taken by the legal representatives of the proprietors of the nursing-home. Mr. William Smith, on their behalf, drew attention on Jan. 21st to the fact that the coroner had stated that Dr. Roche Lynch, the Home Office analyst, would be called at a later stage. Dr. Roche Lynch had already given evidence, and Mr. Smith expressed the fear that the calling of Dr. Roche Lynch a second time might have the effect of completely shattering any point which might have been made in favour of his clients. He considered he ought to have the assistance of an analyst of equal standing, if that were possible. The coroner replied that Dr. Roche Lynch was not in opposition to Mr. Smith or his client, but was present to help them all in the case.

The incident aptly illustrates the problem inherent in inquest procedure. It is the coroner's inquiry, held in the public interest. To him it is an investigation. On the other hand, to parties or witnesses possibly involved, the inquest, as it develops, may assume the nature of a trial. The coroner naturally wants all the help he can get, and will call and recall

witnesses in his own discretion for that purpose. The legal representative of an interested party may seek to shut out evidence or may press for the principles of a criminal trial where there comes a stage when the case for the prosecution is definitely closed. While all coroners will wish to observe the rules of fair play on which British criminal procedure is based, it is certainly impossible to coördinate inquest procedure with that of assize courts where a specific person is accused of a specific offence. So long as the coroner's court continues, he must have a discretion to conduct the proceedings in his own way.

PARIS

(FROM OUR OWN CORRESPONDENT)

FRENCH DENATALITY

THE decline of the birth-rate has for many years been a popular theme for French Jeremiahs, the latest of whom is Dr. L. Devraigne who, in a communication to the Academy of Medicine on Christmas Eve, entertained his audience with certain lugubrious statistics. In 1868 there were 1,034,000 births, whereas in 1934 there were only 667,000, of which 50,000 were in the families of foreigners. Between 1868 and 1934 the population of France has risen only from 38 to 41 millions. Even in the brief interval between 1932 and 1934 there has been a decline of 45,000 in the birth-rate, whereas in Germany in the first quarter of 1935 there were 47,000 more births than in the corresponding quarter in 1934. In the four years 1930-34 the number of marriages was reduced by 44,000 to 298,000, a decline so prodigious that Dr. Devraigne is surely justified in commenting on it with an exclamation mark. It is true that infant welfare work is much more effective now than it was forty years ago, when 150,000-180,000 infants died every year, and in 1934 there were only 47,000 deaths during the first year of life. But even if, as Dr. Devraigne believes, this figure can be further reduced, the denatality of France will not have been successfully combated. If the country is not to become one vast infirmary for old folk, there must be an average of three children per family, and even this modest standard can only be attained, he thinks, by generously subsidising large families from public funds.

THE FAMILY DOCTOR OF THE FUTURE

A correspondent of *Concours Médical*, who signs himself Briau, draws a modest but quite attractive picture of the family doctor of the future. The family doctor of to-day has died a more or less natural death, the cause of which is specialisation. Perhaps this is just as well for, according to Briau, he had fallen from that high estate enjoyed by the contemporaries of Balzac. In those days the practice of medicine was an art; now it is supposed to be a science. The transition from one to the other has left the family doctor in the lurch; losing the art of his predecessors, he has not compensated for this loss by acquiring the science of his contemporaries, the specialists. Having recorded his death with the causes thereof, Briau proceeds to model from the corpse a new family doctor, less resplendent but more useful. He must not expect great emoluments or great honours, but the modesty of his income and station in life is to be compensated for by the feeling that he fits into the picture. His education is to be general and thorough, essentially practical and

unembarrassed by post-graduate courses in special subjects which divert his attention from his primary function. Like a station-master, he is to control and supervise rather than to lay his own hands on any task requiring great technical skill. He is to be responsible for prenatal and postnatal infant welfare, but the confinement itself is to be in the hands of the specialist that he has advised the family to summon. As the child grows older and the parents are tempted to offer themselves the luxury of an imperious (sic) English nurse, he must not let himself

be ousted, and he must remember that what may be good for little Anglo-Saxon children born in the fog of their cold and wet country is not necessarily just what Latin or Celtic babies need. He will prevent scolioses, dystrophies, and the rest by shunting the incipient patient off to an appropriate specialist. Though he must not specialise, the future family doctor must read medical periodicals and attend medical meetings in order to keep abreast of the times and to distinguish between the specialists to avoid and those to consult.

PANEL AND CONTRACT PRACTICE

Temporary Residents

THE London local medical and panel committee recently suggested to the insurance committee that the distribution scheme should be amended so as to provide that in respect of temporary residents in convalescent homes or similar institutions credits shall be given only in those cases in which a continuation card is submitted containing evidence that medical treatment (which should not include an examination for the purposes of the home) has been given. The subcommittee of the insurance committee expressed the opinion that the proposal was worthy of adoption if made applicable to all temporary residents and the panel committee has now decided to vary its proposal accordingly.

Another Case for Clause 7 (2)

Two insurance doctors have just had to appear before the London medical service subcommittee simply because, according to the facts found by the subcommittee, they had handled a case in their own way instead of acting in accordance with the terms of service. A girl, aged 16½ years, became ill and went with her mother to the surgery of the senior partner, receiving treatment for which a fee was demanded. According to her statement to the subcommittee, the mother demurred, pointing out that, although her daughter had not received a medical card, she was in fact insured. The doctor said she should pay and then apply to the committee for a refund, but no fee was actually paid as the doctor had not the necessary change. Next day the junior partner visited the girl at home, and a similar conversation ensued but no fee was paid on this occasion either. A third consultation took place two days later but on this occasion no reference was made to insurance. An account was rendered and was paid, the junior partner telling the mother that she should apply to the committee for reimbursement. The senior partner told the committee that he had no recollection of anything being said about the patient being insured, while the junior partner was positive that nothing was said when he saw the girl. The mother, on the other hand—she is an insured person on the list of the junior partner—was equally positive that both the doctors were made aware of the position and in fact that her application for reimbursement was made at the suggestion of the junior partner. At the conclusion of the hearing both doctors agreed that there had probably been a misunderstanding and they expressed their willingness for the case to be dealt with as though they had issued form G.P.4. The committee found that there had been a failure on the part of the junior partner to comply with the terms of service, but in view of his offer to refund the amount

charged, decided to take no further action in the matter. And all this trouble might have been saved if the practitioners had followed the procedure laid down for their protection in Clause 7 (2) of their Terms of Service.

The Chemist who was Annoyed

A test prescription for Mist. gent. acid. was recently presented to a certain chemist, and in due course the medicine was analysed. The analysts stated that in addition to a trace of hydrochloric acid and possibly a small proportion of infusion of gentian (there should have been 200 and 300 minims respectively) the sample contained hydrobromic acid equivalent to 146.8 minims of acid. hydrobrom. dil., and alkaloids of nux vomica equivalent to approximately 16 minims of extr. nuc. vom. liq. or 190 minims of tinct. nuc. vom. in the 10.65 fluid ounces dispensed. The chemist was invited to explain the discrepancy, but the only remarks offered by him were that "whatever concoction the analyst has been analysing it has nothing whatever to do with the mixture that I dispensed and supplied." In further letters he attacked the staff of the insurance committee, and when writing to say that he did not propose to attend the hearing by the pharmaceutical service subcommittee, he made the somewhat naïve suggestion that it would be remarkable if he could compound Mist. gent. acid. without getting any of the ingredients into the bottle. But he did not take the precaution of having the second half of the mixture analysed by an independent analyst and has only himself to thank that the committee are asking the Minister to withhold the sum of £5 from his remuneration.

A Part-time Assistant

Three insurance doctors, each with the maximum number of insured patients, are in partnership and have recently had to refuse new acceptances in order to bring their lists within the permitted maximum. The partners realise that to refuse acceptances may adversely affect their practices, and have applied for the consent of the insurance committee to their employing an assistant, but they take the view that the extra number of insured persons likely to secure inclusion in their lists would not justify the expense of a whole-time assistant, and so they have asked to be allowed to have an assistant for two days a week until the extra number of insured persons justifies the appointment of a full-time assistant. The maximum additional number of patients who may be accepted by virtue of employing an assistant is 1500, and the committee have acceded to the doctors' request upon the condition that while the assistant is employed for not less than two days a week the additional number of insured persons accepted shall not exceed 350.

PUBLIC HEALTH

Diphtheria v. "Bacteriological Diphtheria"

PUBLIC authorities who control not only schools, day and residential, in which cases of diphtheria may occur but also infectious diseases hospitals to which they are removed are as much concerned to limit the number of cases as to economise the occupation of beds. There can be no question that the child with definite or even suggestive clinical evidence of diphtheria is properly removed to hospital for further investigation and treatment. There is equally no question that the increasing practice of indiscriminate swabbing without virulence tests and without determination of the state of immunity by Schick tests results in the unnecessary hospitalisation of numbers of children who are neither in danger themselves nor dangerous to the community from which they are removed. Entitled "Nomenclature of Diphtheritic Infections," a report just published¹ presents the conclusions of a L.C.C. departmental committee appointed by Sir Frederick Menzies. The title is an understatement of the contents of the report which covers far wider ground, since procedure is suggested for dealing with children, both immunised and non-immunised, in schools and homes of all types from whom positive swabs have been obtained but who show no clinical manifestations of diphtheria.

Diphtheritic infections include the various clinical forms of the disease, "bacteriological diphtheria"—that "tautological and meaningless" label—and carriers both convalescent and contact. Diphtheria is defined in the report as the reaction of the body to virulent strains of the *C. diphtheria*, and the keynote throughout is insistence upon virulence tests of the organism in the absence of clinical signs of the disease. Attention is drawn to the danger to others of the child suffering from anterior nasal diphtheria, in the opinion of the committee the commonest source of infection, particularly in schools and hospital wards. The condition, although intensely infective, produces as a rule nothing more than nasal discharge and debility which may be unremarked until severe types of the disease have arisen in other children as the result of contact. There can be no doubt that frank nasal diphtheria is a greater menace than the occult carrier state, since the dosage of infection transmitted is likely to be greater.

In the production of convalescent carriers there are, the report says, only two factors: a clinical attack of the disease and an unhealthy condition of the nasopharyngeal mucosa. The factors which are operative in producing "healthy" or contact carriers are the opportunity for and amount of infection and the local condition of the respiratory passages under which the bacillus may survive. What results from the contact-carrier state depends upon the state of immunity at the time of infection. Thus non-immunes may contract clinical diphtheria or, as the result of summation of subclinical doses of infection, attain "natural" immunity. Immunes may be transient contact carriers or become chronic carriers. It is emphasised that since they do not contract clinical diphtheria, the greater the number of immunes in a closed community the higher the carrier rate tends to become. In a community wholly immune, carriers are not harmful but bene-

ficient, since the repeated infection of immunes tends to raise, or at least to maintain, the level of anti-toxic immunity. The moral of this is obvious. The presence of virulent strains of the diphtheria bacillus in any considerable community of children is well-nigh inevitable. If some of these children are susceptible to the disease, outbreaks of clinical diphtheria are from time to time almost as inevitable.

Hence the report advocates the determination of the state of immunity of all inmates by means of the Schick test and the active immunisation of all positive reactors, confirmatory Schick tests being insisted upon. Half-measures are not only useless but detrimental to the progress of immunisation. It is among institutions whose inmates are only in part immune, or whose state of immunity following prophylactic injections has not been verified, that the objector (always on the lurk for mischief) finds some of his most venomous barbs. This lead from the largest public health authority in the world is to be welcomed by those who would put an end to the suffering of children from a preventable disease. The report proceeds to lay down the steps which should be taken for the disposal of cases under the various conditions of institutional practice, and concludes with an appendix in which are described the correct method of swabbing and the details which should be supplied to the bacteriologist; the inoculation of media; standard forms of report which should be used by bacteriologists; and the clinical significance of the bacteriological findings.

Practitioners who rely upon the morphological diagnosis of the diphtheria bacillus in a smear or culture may study with advantage the following scheme for the complete identification of the organism given on p. 16 of the report.

Stages in the Complete Identification of Virulent Diphtheria Bacilli and Time Occupied (in Days) from Taking the Swab

Day	Stage	Swab	
0	1st	Löffler	
0	2nd		
1	3rd	Micro. positive	Micro. negative.
1	4th	Inoculate tellurite plate	
3 (m.)	5th	Diphtheria-like colonies	Negative (diphtheroids or Hofmann only).
3 (m.)	6th	Inoculate serum agar	
3 (aft.)	7th	Inoculate fermentation tubes	
	8th	Read fermentation tests	Negative (diphtheroids or Hofmann only).
		True diphtheria bacilli	
4	9th	Virulence test	
5 or 6	10th	Result of test	Non-virulent diphtheria bacilli.
		Virulent diphtheria bacilli	

m. = morning; aft. = afternoon.

¹ Report of Departmental Committee (A. F. Cameron, E. H. R. Harries, A. Joe, J. E. McCartney, and A. Topping). London: P. S. King and Son, Ltd. No. 3161. 3d.

Intended primarily for the guidance of medical officers in the L.C.C. service, the report, which is a

reflex of modern practice in the control of diphtheria in institutions, should find a wider medical public. It contains a good deal for threepence.

Rat Plague

Early in December last a dead rat found in a grain warehouse at the docks at Liverpool was submitted to the bacteriologist for examination and found to be infected with plague. An intensive search and rat destruction campaign was immediately carried out in the vicinity, with the result that a few days later one of many trapped rats was also found to be infected. Although vigorous action has continued to be taken it would appear that no other plague-infected rats have been found, and there have been no human cases. The docks of Liverpool have an extensive trade with South America and the East, from both of which parts of the world plague-infected rats may gain access to this country, especially from grain-bearing ships.

It would probably be true to say that the destruction of rats on ships and on docks, and the search for plague-infected rats, has come to be the major activity of port sanitary authorities. During the year 1934, 2739 rats were caught in ships at the port of Liverpool, of which all but 2 were of the black variety, and in addition 2121 rats were caught on the quays, of which all but 156 were black. It is,

of course, the black variety of rat which is most likely to be infected with plague. The examination of rats for evidence of plague infection is carried out extensively; the number of rats examined at Liverpool in 1934 was 3486, of which all but 227 were black. Although the most careful precautions are taken (by exercising the powers and duties prescribed by the Port Sanitary Regulations, 1933) to keep down the rat population on ships, and to prevent the access of rats from ships to the shore, the danger of the introduction of plague is a cause of constant concern to port medical officers of health, and the prompt detection of the presence of plague-infected rats at Liverpool is evidence of the attention given to the subject. The more intensive activities which have followed the discovery seem to give assurance that no enzootic will occur in the area. Under present-day powers and administration a recurrence of the widespread rat infection which took place in East Anglia early in the century is highly improbable.

It is only occasionally that the importance of the large-scale routine work of the port sanitary authorities is prominently brought before the public, but port medical officers are well aware that if the work of their staffs was not carried out with assiduity and intelligence occurrences of this kind would not only be more frequent, but also much more serious.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

The death of H.M. King George V.—The *London Gazette* of Jan. 24th publishes Orders in detail for the mourning to be worn by Officers of the Royal Navy and Royal Marines, Officers of the Army, and Officers and Warrant Officers of the Royal Air Force for six months from Jan. 21st, ending July 20th, 1936.

Surg. Comdrs. G. W. Woodhouse to R.N. Hospital, Portland; R. W. Higgins to *President* for course; and W. G. C. Fitzpatrick to *Victory* for R.N.B., and to *Vernon*.

Surg. Lt.-Comdr. T. F. Crean to *Pembroke* for R.N.B., Chatham.

Surg. Lt. (D.) R. W. Stevens promoted to rank of Surg. Lt.-Comdr. (D.).

Surg. Lts. D. W. Walker to *Pembroke* for R. M. Infirmary, Deal; and T. McCarthy to *Furious*.

VACANCIES FOR MEDICAL OFFICERS AND SURGEON LIEUTENANTS (D.)

Applications are invited for eight vacancies in April for Medical Officers in the Royal Navy. Copies of the regulations for entry, conditions of service, &c., may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools. Applications for entry must be received not later than Feb. 22nd.

The establishment of Dental Officers in the Royal Navy has been increased and applications are invited for appointment to commission as Surgeon Lieutenants (D.). Application forms and a pamphlet may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1. Applications for entry in March must reach the Medical Director-General not later than Feb. 6th.

ROYAL NAVAL VOLUNTEER RESERVE

H. B. Howell entered as Proby. Surg. Lt.
Proby. Surg. Lt. H. J. Wade to *Excellent*.
Proby. Surg. Sub-Lts. D. S. Macphail and J. A. Shepherd to be Surg. Sub-Lts.

ROYAL ARMY MEDICAL CORPS

Maj. T. C. Bowie retires on ret. pay.
Capts. T. W. Davidson and C. R. Christian to be Maj. (Substituted for notification in the *Gazette* of May 8th, 1934.) (*Vide THE LANCET*, May 19th, 1934, p. 1080.)
Capt. J. G. E. Vachell to be Maj. (Substituted fo

notification in the *Gazette* of Feb. 15th, 1935.) (*Vide THE LANCET*, Feb. 23rd, 1935, p. 450.)

TERRITORIAL ARMY

Capt. G. W. Wright, M.M., T.D., to be Maj.
Lt. R. Rutherford to be Capt.
Hugh Weir (late Cadet Serjt., Glasgow Univ. Contgt., Sen. Div., O.T.C.), to be Lt.
James Lockhart Gowan (late Cadet, George Watson's Coll. Contgt., Jun. Div., O.T.C.), to be Lt.

ROYAL AIR FORCE

The undermentioned Flying Offrs. are promoted to the rank of Flight Lt. :—

A. W. Smith, J. W. Patrick, J. S. Wilson, C. A. Lewis, R. G. James, and G. H. Stuart.

Flying Offrs. C. M. Carlyle-Gall to R.A.F. Station Aldergrove; E. B. Harvey and D. S. MacL. MacArthur to Medical Training Depot, Halton, on appointment to short service commissions.

Flying Offr. R. S. Peill to R.A.F. Station, North Coates Fitties.

Dental Branch.—Flight Lt. J. G. Stewart is transferred to the Reserve, Class D.

Flying Offrs. D. P. Boyle to No. 5 Flying Training School, Sealand; K. G. Swiss to No. 3 Flying Training School, Grantham; and H. M. G. Williams to Headquarters, Coastal Area, Lee-on-the-Solent.

VACANCIES FOR COMMISSIONS IN THE MEDICAL BRANCH

Applications are invited from Medical Men for appointment to Commissions in the Medical Branch of the Royal Air Force, for entry in May, 1936. Copies of the regulations and form of application may be obtained on application from: The Secretary, Air Ministry (D.M.S.), Adastral House, Kingsway, W.C.2. Completed applications from intending candidates for the vacancies in May, 1936, must be received in the Air Ministry not later than March 17th, 1936.

INDIAN MEDICAL SERVICE

Col. W. H. Hamilton, C.I.E., C.B.E., D.S.O., F.R.C.S., I.M.S., is apptd. Hon. Physician to the King, Oct. 22nd, 1935, vice Col. E. C. Hodgson, D.S.O., I.M.S., retd.

Indian Medical Department.—Maj. (Sen. Asst. Surg.) L. P. Gernon retires.

USE OF ANALGESICS BY MIDWIVES

REPORT OF AN INVESTIGATION BY THE BRITISH COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS¹

At the request of the National Birthday Trust Fund the British College of Obstetricians and Gynæcologists has carried out an investigation to ascertain if there is any form of analgesia (relief from pain) which can be used with safety and success by a midwife in the absence of a medical practitioner. The trial has been made in institutions, as adequate medical supervision and facilities for the necessary observation and accurate recording of results are more readily available in such places. Thirty-six hospitals, for the most part maternity hospitals or departments attached to medical schools, accepted the invitation to take part in the investigation.

Five methods were adopted for investigation: (1) chloroform capsules, (2) the Christie Brown chloroform inhaler, (3) the Mennell chloroform inhaler, (4) the Minnitt gas-and-air apparatus, (5) the administration of paraldehyde per rectum. The records of nearly 10,000 cases have been studied and classified into three main groups: (1) nitrous oxide and air, (2) chloroform, (3) paraldehyde.

Nitrous Oxide and Air

Nitrous oxide and air was administered with the Minnitt apparatus to 3865 cases, and in 627 of them an additional anaesthetic was administered, mainly on account of some obstetric difficulty. Nitrous oxide and air was thus administered to 3238 cases without any supplementary anaesthetic or analgesic. In this series there were three maternal deaths which were in no way due to the analgesia. Among the 627 cases in which an additional anaesthetic was administered there were six maternal deaths; in every case the death was the result of serious obstetric difficulty and in no case was it attributable to the administration of the gas and air.

The stillbirth-rate when the Minnitt apparatus alone was used was 2.0 per cent. When administered by a sister, staff-nurse, or pupil-midwife it was 1.2 per cent. The higher stillbirth-rate in cases undertaken by a medical practitioner is accounted for by the fact that he would be more likely to be called upon in difficult cases in which a relatively high stillbirth-rate is to be expected. When a full anaesthetic was given (frequently on account of some obstetric abnormality) the stillbirth-rate was 4.3 per cent. The stillbirth-rate for the whole series, however, shows that the method does not involve any added risk to the foetus, and the low stillbirth-rate when the analgesic was self-administered (or administered by a pupil-midwife) indicates that the actual administration does not call for more special skill than that which may be acquired by a midwife during her period of training.

The number of cases in which obstetric interference was necessary is an indication of the degree to which the normal forces of labour were interfered with. In the series of 3865 it was 8.4 per cent. (forceps delivery alone 6.6 per cent.), and as these figures compare favourably with the interference-rate in ordinary practice, the conclusion is justified that this method has no deterrent influence on the natural course of labour.

¹ The report, of which this is a summary, was passed by the College at its meeting on Jan. 25th, 1936, and is signed by the president, Sir Ewen Maclean. Copies may be had, price 1s., from the hon. secretary of the College, 58, Queen Anne-street, London, W. 1.

The records of the patients who received analgesia from the Minnitt apparatus have been analysed (Table I.) as regards the efficacy of the method.

TABLE I

	Per cent.
Satisfactory	77.0
Doubtful	5.3
Unsatisfactory	17.7

Investigation was further made into the relative effectiveness of this form of analgesia when self-administered or when administered by persons of varying degrees of experience. The proportion of cases in which satisfactory analgesia was obtained with various classes of administrators is set out in the table below. Table II. is an analysis of 3238 cases in which the Minnitt gas-and-air apparatus was used without any additional anaesthetic or analgesic.

TABLE II

Efficacy of Gas-and-Air Analgesia in the Hands of Various Administrators

Administered by—	Total cases.	Percentage of satisfactory cases.
Patient herself	1086	88.0
Pupil midwife or Medical student 	553	81.4
Midwife	797	82.1
Medical practitioner	802	82.8

CONCLUSIONS

(1) The investigation has proved that the administration of gas and air by the Minnitt apparatus is safe for use by midwives in hospital, provided that a recent examination by a medical practitioner has revealed no contra-indication thereto.

(2) The use of that apparatus should be restricted to those midwives who have had a special training in its use, and who have shown themselves capable of managing it. Such training could be carried out concurrently with that for the certificate of the Central Midwives Board when the proposed longer period of training is adopted. For those already holding the C.M.B. certificate a special course would be required. The reasons for stressing the importance of a long training are that it requires considerable experience to learn the essentials of obstetric analgesia. Furthermore, experience in mechanical adjustments and in the changing of gas cylinders is essential if the machine is to work efficiently.

(3) Gas and air administered by the Minnitt apparatus produces satisfactory analgesia in a high proportion of cases. Sometimes, however, there is a restlessness and difficulty in controlling the patient; it is essential, therefore, that one other responsible person should be present in addition to the midwife in charge of the case.

(4) Further experience is necessary before the suitability of the Minnitt apparatus for domiciliary practice is proved, as this investigation has only been carried out in hospitals where additional help was always readily obtainable.

(5) Owing to the weight and bulk of the apparatus, transport would present serious difficulties if used in domiciliary practice, but it is possible that the wider use of "light" cylinders and further simplifications of the apparatus may go far to solve this problem.

(6) The apparatus presents certain mechanical difficulties which have necessitated return to the makers. Whilst due regard must be given to those difficulties, it may be possible to overcome them, once there is a sufficient demand to stimulate mecha-

nical improvements. It must be borne in mind, however, that a certain amount of mechanical aptitude would be still required to change cylinders of gas and to make minor adjustments. Such adjustments involve the use of a spanner and the frequent inspection of washers and joints.

(7) The cost of the apparatus is a handicap to general use. Apart from the initial expense, the cost of the nitrous oxide is high. Moreover, there is a serious risk of wastage owing to the fact that, as the apparatus is now constructed, leakage may occur at many places unless constant attention is given to minor adjustments.

Chloroform

In the majority of patients chloroform analgesia was used alone, but in some it was necessary (frequently on account of some obstetric abnormality) to supplement the analgesia with general anaesthesia. Thus, for each method the patients have been divided into two groups (Table III.), and the maternal deaths in each group have been recorded.

TABLE III

Maternal Deaths with Different Methods of Chloroform Analgesia

Method.	Analgesia alone.		Analgesia plus general anaesthesia.	
	Total cases.	Deaths.	Total cases.	Deaths.
Chloroform capsules ..	2338	1	194	0
Mennell inhaler ..	1430	1	141	2
Christie Brown inhaler..	809	0	63	2
Total	4577	2	398	4

Thus the maternal mortality-rate in this group of 4975 patients was 1·2 per thousand. From a study of the details of these six deaths, the conclusion reached is that chloroform was directly responsible for death in one case, that it was probably an important factor in the fatal issue in two cases, and that it was in no way responsible for death in three cases.

The total stillbirth-rate for all cases in which the analgesia was obtained (Table IV.) by the use of

TABLE IV

Stillbirth-rate with Different Methods of Chloroform Analgesia

Method.	Analgesia alone.		Analgesia plus general anaesthesia.	
	Total cases.	Stillbirth rate per cent.	Total cases.	Stillbirth rate per cent.
Chloroform capsules ..	2338	2·4	194	17·5
Mennell inhaler ..	1430	1·3	141	4·3
Christie Brown inhaler..	809	1·9	63	3·2

chloroform was 2·6 per cent. It includes all cases in which obstetric interference became necessary after the analgesia had been started, so that it may be said that there is no evidence that the chloroform analgesia is attended by increased risk to the foetus.

The interference-rate for all cases receiving chloroform capsules was 5·3 per cent. (forceps delivery 3·7 per cent.). Thus there is no evidence that the

use of chloroform as an analgesic in these cases caused any material interference with the normal forces of labour. Table V. shows the efficacy of the analgesia produced by the three methods investigated.

TABLE V

Efficacy of Analgesia with the Three Methods of Chloroform Analgesia

	Chloroform capsules, per cent.	Mennell inhaler, per cent.	Christie Brown inhaler, per cent.
Satisfactory ..	81·8	84·9	78·8
Doubtful ..	3·7	2·7	6·3
Unsatisfactory ..	14·5	12·4	14·9

Investigation has been made into the proportion of the patients in whom satisfactory analgesia was obtained when the analgesic was administered by persons of varying degrees of experience. Table VI. is an analysis of the cases in which no additional anaesthetic was given.

TABLE VI

Efficacy of Chloroform Analgesia in the Hands of Various Administrators (percentage of patients who obtained satisfactory analgesia)

Administered by—	Chloroform capsules.		Mennell inhaler.		Christie Brown inhaler.	
	Per cent.	Cases.	Per cent.	Cases.	Per cent.	Cases.
Patient herself ..	87·7	(277)	83·4	(177)	82·1	(252)
Pupil midwife or medical student	81·8	(1239)	81·5	(92)	82·2	(157)
Certified midwife	83·9	(695)	92·1	(559)	81·3	(347)
Medical practitioner	86·6	(127)	93·7	(302)	86·8	(53)

Note.—The figures in parentheses represent the total numbers of cases in the several groups.

CONCLUSION

Chloroform by any method should not be used by midwives acting alone. This conclusion has been reached with regret, but both the immediate and delayed dangers which are well recognised occurred in this investigation, and it is not possible fully to guard against such occurrences if the administration of chloroform is in inexperienced hands. This finding should not be taken to prejudice the administration of chloroform in midwifery by registered medical practitioners who, aware of the dangers, can take precautions to lessen the risks.

Paraldehyde

While there can be no doubt that in some selected cases the use of paraldehyde, given in oil per rectum during the first stage of labour, may be a valuable means of relieving pain, the general opinion of those who have used it as a routine method in this investigation is that it is unsuitable for general use by midwives. In arriving at this conclusion they have had in mind the technical difficulties in administering the drug, the need for careful selection of suitable patients, the choice of time for giving the injection, its variable action even when patients are carefully selected, and the inadequate analgesia at the time of the actual birth of the child. This last is probably the most important objection to its widespread use by midwives, since, even if effective in the early stages of labour, some additional method of analgesia must be provided if the pain associated with the moment of birth is to be relieved.

CORRESPONDENCE

BACTERIOLOGICAL TESTING OF MILK

To the Editor of THE LANCET

SIR,—Your issue of Jan. 11th comments on an extract from my annual report for 1934, dealing with the bacteriological examination of samples of graded milk, which appeared in the *Medical Officer* of Dec. 28th, 1935. "Dr. Howell," it is remarked, "is hardly being fair when he assumes that variations in count are due to the failure of bacteriologists to 'faithfully and carefully carry out the suggested procedure.'" Other factors are suggested as the likely cause of the widely different results given by different laboratories of the examination of samples of the same milk. "The factor which probably has most effect on the bacterial content of milk is the state of the weather, which is altogether outside the bacteriologist's control." Unless samples are transported to the laboratory on ice "there may be big variations in bacterial growth within a short period of transit."

This fact is of course well known by everyone with an elementary knowledge of milk bacteriology, but cannot be advanced as an explanation of the wide divergence of the figures in the reports I have quoted. One bottle of milk was taken and after thorough shaking was divided into six parts. The milk, before division, and the bottles into which it was placed were of an even temperature. The bottles were immediately packed into an efficient ice-box and conveyed to the laboratories. The difference in time taken for delivery of the parts which were reported to have the lowest (9270) and the highest (3,400,000) total counts was about 20 minutes. The temperature of the milk upon arrival was stated by the laboratories to be 13°C. in the first case and 11°C. in the second case. It will be seen that the part for which the lower temperature was given was stated to have a bacterial count 360 times greater than that of the part for which the higher temperature was given. As a further proof that the temperature of the milk had nothing to do with the difference in the figures I have quoted, I would point out that each laboratory gave the same temperature for the two parts which they each examined, yet each laboratory gave different figures for the two parts, in one case the results varied from 147,000 to 3,400,000.

I fully appreciate the difficulties of trying to standardise a test of this sort and I have pointed out that particular attention must be paid to every detail. Your article states, "There are mechanical faults such as errors in the graduation of pipettes to be controlled"—but surely this is a difficulty quite easy to overcome. Every properly equipped laboratory should have standardised equipment.

The Milk and Dairies (Amendment) Act gives power to a local authority to withdraw a licence to sell graded milk, if reports on a dairyman's milk show that samples do not comply with the standards laid down. It would be most unfair if such action was taken on reports which gave incorrect figures due to the use of improperly graduated pipettes in the laboratory. I agree that the human element plays an important part in the bacteriological examination of milk. I still consider, however, that the tests are worthless unless they give more comparable results. I hold no brief for the dairyman who does not take every precaution to safeguard his milk but, at the same time, I sympathise with the man who may be called upon to answer charges on unreliable data.

Dairymen have been and are being prosecuted for selling graded milks not in conformity with the standards. In view of my experience it may well be that some at least are innocent of the charges made against them.—I am, Sir, yours faithfully,

J. B. HOWELL,
Jan. 24th. Medical Officer of Health, Hammersmith.

MEDICAL EDUCATION AND BLOOD EXAMINATION

To the Editor of THE LANCET

SIR,—I should like to endorse all that Dr. Herbert Brown says in his letter in your issue of Jan. 11th. The medical journals have unfortunately given little encouragement to the routine examination of the blood in diagnosis and prognosis in their editorials on the subject, and I was told by the head of a preparatory school that he wished me to discontinue "blood examinations" as "the boys didn't like it and other doctors were able to do their job without it."

The discovery of early leucocytosis in a lobar pneumonia saves much exhausting examination of the chest. The search for the return of the eosinophils justifies a daily differential count, the "drift from the left" being also noted, and are signs of improvement so much more certain than any symptom. There is just one additional point to stress—one should have a record of the patient's blood picture in normal health. To quote Dr. Brown, "the process is interesting, even fascinating" and extremely valuable. He has, I think, mentioned the one drawback—it takes an hour in each case.

I am, Sir, yours faithfully,
H. ANGELL LANE.
Battle, Sussex, Jan. 22nd.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
JAN. 18TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2554; diphtheria, 1283; enteric fever, 13; acute pneumonia (primary or influenzal), 1219; puerperal fever, 46; puerperal pyrexia, 105; cerebrospinal fever, 22; acute poliomyelitis, 3; acute poliomyelitis, 2; encephalitis lethargica, 5; dysentery, 23; ophthalmia neonatorum, 87. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 24th was 3964, which included: Scarlet fever, 1120; diphtheria, 1129; measles, 475; whooping-cough, 610; puerperal fever, 19 mothers (plus 13 babies); encephalitis lethargica, 283; poliomyelitis, 5. At St. Margaret's Hospital there were 20 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 3 (3) from enteric fever, 58 (7) from measles, 6 (1) from scarlet fever, 27 (11) from whooping-cough, 42 (3) from diphtheria, 37 (11) from diarrhoea and enteritis under two years, and 89 (18) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza is falling, the total deaths for the last seven weeks (working backwards) being 89, 110, 110, 80, 67, 62, 45. The deaths this week are scattered over 52 great towns, Leeds reporting 7, Birmingham 6, Newcastle-on-Tyne 3, no other great town more than 2. Liverpool had to report 19 deaths from measles, Manchester 9, Croydon and Salford each 3. Liverpool also had 4 deaths from whooping-cough, Manchester 2. Deaths from diphtheria were reported from 28 great towns, Hull, Manchester, Oldham and Sunderland each reporting 3; Leeds, Liverpool, Birmingham, and Swindon each 2.

The number of stillbirths notified during the week was 259 (corresponding to a rate of 42 per 1000 total births), including 43 in London.

OBITUARY

**WILLIAM BLAIR-BELL, M.D. Lond.,
F.R.C.S. Eng.**

LATE PRESIDENT, BRITISH COLLEGE OF OBSTETRICIANS AND
GYNÆCOLOGISTS

THE news of the sudden death of Prof. Blair-Bell, which occurred on Saturday last, Jan. 25th, has been received with deep regret by the medical world and a large circle of public and private friends. He enjoyed a great and even international reputation as gynæcological and obstetrical surgeon with a large scientific outlook.

William Blair-Bell was born at Wallasey in 1871, the son of the late Dr. William Bell, J.P., and Helen, daughter of the late General Butcher. He received his general education at Rossall and went for his medical training to King's College, London, where

PROF. BLAIR-BELL

Photograph by Elliott & Fry

he was a successful student, Warneford and Junior medical scholar, prizeman in physiology and obstetric medicine, and Tanner prizeman in gynæcology. He took the double English diploma in 1896 and graduated as M.B. London in the following year, when he was elected an Associate of King's College. He was prosector at the Royal College of Surgeons of England, and demonstrator of anatomy and physiology in King's College, and early showed his mark

as clinician and observer by papers in the King's College Hospital Reports, the *Edinburgh Medical Journal*, and *The Lancet*. He proceeded to the M.D. Lond. in 1902 and took the B.S. Lond. in 1904.

He now returned to Liverpool, with which city he was for the next 30 years and more so importantly connected. He was appointed in 1905 gynæcological surgeon in charge of out-patients at the Royal Infirmary, Liverpool, and held appointments also at the Wallasey Cottage Hospital and the Wallasey Dispensary. His work immediately attracted wide attention. He communicated regularly to the *Proceedings* of the North of England Gynæcological Society, and his coöperation became sought by the editors of systematic treatises. He wrote the articles on malformation of the uterus, injuries to the uterus, fistulæ of the uterus, and subinvolution of the uterus, in Latham and English's system of treatment; he wrote the section on obstetric operations and on sexual functions in women in the "Practitioners' Encyclopædia," and the chapter on operations on the Fallopian tubes in Burghard's "System of Operative Surgery." His papers in *The Lancet*, *British Medical Journal*, *Practitioner*, and the *Proceedings* of the Royal Society of Medicine, sometimes alone and sometimes in collaboration, all showed him to be a resourceful surgeon with an unusual knowledge of physiology—papers published in the *British Medical Journal* on the physiology of the

female genital organs (in collaboration with Pantland Hick) and a communication to the Royal Society of Medicine on the relations of calcium metabolism to menstruation may be instanced.

In 1910 Blair-Bell gained the John Hunter medal of the Royal College of Surgeons of England and the triennial prize for an essay on the anatomy and physiology of the pituitary body and the relationship with disease of its abnormal and morbid conditions. Two years later he delivered the Arris and Gale lectures before the College, taking as his subject the genital functions of the ductless glands in the female. The lectures which were printed in *THE LANCET* with full illustrations showed not only the advanced nature of Blair-Bell's physiological studies and his acquaintance with detailed laboratory work in biochemistry, but also his wide reading and philosophical outlook. In 1913 he became full gynæcologist and surgeon at the Royal Infirmary, and in 1921 he was appointed professor of these subjects in the university. He held the chair in the university for ten years and was emeritus professor at the time of his death. As a teacher he was thoroughly in his element; it is not too much to say that under him there flourished the best teaching department in gynæcology of any British school.

Blair-Bell, who had now been president of the North of England Gynæcological Society and vice-president of the section of obstetrics and gynæcology at the Royal Society of Medicine, made in 1925 his first long and formal statement of views upon cancer, which afterwards became the subject of much discussion. He delivered on Nov. 10th of that year, before the Academy of Medicine in Toronto, an address on the specific character of malignant neoplasia with special reference to the control of cancer from this standpoint, and in the course of the address revealed the intensive study of the subject on which he had been engaged in coöperation with a group of Liverpool workers.

HIS WORK ON CANCER

Prof. Walter J. Dilling, director of the department of pharmacology of Liverpool University, sends the following account of this work:—

"It is a sorrowful privilege for one who has been closely associated with Blair-Bell's investigation into the nature and control of malignant disease to write a historical eulogy upon his brilliant and indefatigable endeavours to elucidate this problem. He was urged to research upon cancer by a yearning for knowledge with which he might alleviate human suffering and prolong life, and, in 1909, he formulated his "working hypothesis"—namely, that the chorionic epithelium, particularly the syncytium, was a normally malignant tissue and that a means, which could check its development, would be useful in arresting the progress of malignant growths.

"At first he explored the idea that the invasive properties of chorionic epithelium might be arrested by embryonic or placental extracts, but, when these failed, he concentrated his attention on the fact that lead salts caused abortion and were particularly deleterious to young life, surmising, as a corollary, that they might restrain the growth of neoplasms. The discovery that lead destroyed spermatozoa in the testes and induced coagulation necrosis in the ectodermal tubules of the chorion, encouraged him to treat, on Nov. 9th, 1920, an inoperable spheroidal-celled medullary carcinoma of the breast by intravenous injections of a partly colloidal lead iodide—

within a month the growth had practically disappeared, the enlarged glands subsided, and this patient is still alive. Other hopeful improvements were achieved in a variety of cases and, at a meeting on Jan. 30th, 1923, the late vice-chancellor of Liverpool University, Dr. J. G. Adami, inspired the formation of a Cancer Research Committee, which consisted originally of Sir Robert Jones, Messrs. J. A. Smith and Rex Cohen, with the present registrar of the university, Mr. Edward Carey, as acting secretary, in order to subsidise and facilitate researches upon Blair-Bell's theories and remarkable clinical results.

"Blair-Bell's knowledge of the modern advances in the medical sciences was admirably and amazingly comprehensive, but he recognised that satisfactory and rapid progress towards his objective could be achieved only by employing the 'Aggregate Mind' of his scientific colleagues. His preliminary results and his aspirations were communicated to Prof. W. C. M. Lewis (physical chemistry), the late Prof. E. E. Glynn (pathologist), and the writer (pharmacologist), who agreed to assist in the investigation. Funds, provided at first through the generosity of the Cancer Research Committee—notably by Mr. Rex Cohen—defrayed the cost of early researches and provided free treatment for poor patients in nursing homes; but, later, when the Liverpool Medical Research Organisation was incorporated for charitable purposes, financial support for the work was derived partly from voluntary subscriptions and partly from the fees of patients. Cordial coöperation was maintained between the scientific and clinical workers at the frequent meetings with Blair-Bell, when results were criticised and the scientific staff informed of the clinical effects or defects of new preparations of lead. At these discussions Blair-Bell's intellect was dominant, and displayed an alert elasticity with quickness of perception which justified his position as director and organiser of researches covering extensive fields of modern science.

"Publications by Blair-Bell and members of the scientific and clinical staff appeared from 1922 onwards, and by 1930 some 64 papers had recorded the results of intensive investigations on many aspects of the cancer problem and of the influence of lead on normal and malignant tissues. These researches were subsequently collected and co-related by Blair-Bell in 'Some Aspects of the Cancer Problem,' and a consideration of the evidence contained therein will vindicate Blair-Bell's reputation from the suggestion that he maintained undue reticence about his methods or results, will substantiate the reasons for his caution in endeavouring to restrict the general therapeutical use of lead compounds in malignant disease until their specific value was more definitely determined and their toxicity more easily controlled, and will also justify his belief that lead salts exert an inhibitory influence on some forms of neoplasms. Interest in the work was excited in many parts of the world, and supporting evidence accumulated from many sources, amongst others from Carter Wood in America. As the investigation proceeded, changes and—latterly from lack of funds—restrictions in the fields of the research became necessary. Prof. I. M. Heilbron's collaboration—and recently that of Prof. A. Robertson—achieved the synthesis of many less toxic compounds of lead and the beneficial effects of these in selected cases continued to maintain the hope that the pursuit of this line of inquiry would ultimately yield a compound of lead which possessed greater and more reliable inhibitory effects on tumours both in animals and in man.

"Although he retired from his chair and active practice in 1931, Blair-Bell still maintained an intimate relationship with this research work which, under the direction of Dr. Morris Datnow, continues, so far as restricted funds permit, to be prosecuted actively in Liverpool, both in its scientific and clinical aspects and with results which continue to support the view that intravenous injections of suitable lead compounds do cause in a percentage of cases a retardation or even retrogression of some malignant growths. The work of the Liverpool Medical Research Organisation as a scientific body is a memorial, if still imperfect and incomplete, to the untiring zeal and devotion of Blair-Bell to the advancement of medical science, an objective for which he was always prepared to make personal sacrifices."

Blair-Bell, while frequent in his contributions to contemporary literature, had a useful treatise to his credit dating from an early period in his career. In 1911 appeared his large treatise, the *Principles of Gynaecology*, in which he endeavoured to present a complete and modern survey on which gynaecology should be established. The work was concise and readable, drawn up on a simple and logical arrangement, and admirably produced. While following academic lines in general he challenged attention by the stress which he laid on the importance of the calcium content of the blood and on the large part played by the secretions of the ductless glands in the causation of certain gynaecological conditions. In many directions the lapse of time would seem to have confirmed observations which were not all at the time generally accepted. This was his only textbook.

FOUNDATION OF THE COLLEGE

Blair-Bell erected a permanent memorial to his energies and his high conception of his branch of medical and surgical work when he became the prime advocate of the foundation of the British College of Obstetricians and Gynaecologists. He put forward vigorous arguments for the institution of such a college; he replied trenchantly to those who held the opposite view, and when in 1929 the college came into being it was recognised as absolutely fitting that he should be elected the first president. At the last dinner of the college Lord Dawson spoke of him as "the restless, lovable torch-bearer who never forgot—or allowed anybody else to forget—that he was bearing a torch," and his branch of the profession will never forget their debt to him.

Dr. J. S. Fairbairn, Blair-Bell's immediate successor in the presidency, writes:

"Blair-Bell's was a striking and forceful personality. Gaunt with ascetic features that did not belie the earnestness and grim determination that lay beneath them, he pursued whatever he took up with almost fanatic zeal. Gifted with a fine intellect, the power of dramatic expression, and of wide interests, he was a delightful host and companion. No one of his day and generation exercised a greater influence on British gynaecology than Blair-Bell, an outstanding instance of which was his prominent part in the foundation of the British College of Obstetricians and Gynaecologists. In spite of indifferent health, he threw himself, body and soul, into the work of drawing up its constitution and seeing through its incorporation, and, after his election as its first president, of establishing it in the position he had determined it should occupy. He had ambitions regarding the high place the new college should take and was inclined to be impatient with those, both within and without the

college, who were unable to accept his own estimate. There can be little doubt that this impatience arose in great measure from the knowledge that his life hung by a thread and might end as it did. He was certainly lavish in the expenditure of his strength and energy, for no details escaped him or were too small for his undivided attention. Nowhere will the passing of William Blair-Bell be more deeply mourned than in the college that meant so much to him and owes so much to him."

The following is a brief enumeration of the appointments that Blair-Bell held at the time of his death. He was consulting gynæcological and obstetrical surgeon to the Royal Infirmary and the Maternity Hospital, Liverpool, and emeritus professor at the university of those subjects. He was the consulting director of the Liverpool Medical (Cancer) Research Organisation, president of the Royal Infirmary, Liverpool, and honorary fellow of many obstetrical societies, British and foreign. He was elected fellow of King's College, London, in 1928, and F.R.C.S. Eng. in 1929. He was an honorary fellow of the American College of Surgeons, the universities of Liverpool and Glasgow gave him the LL.D. degree, and he was a Commander of the Royal Order of the Star of Roumania.

Prof. Blair-Bell married his cousin, Florence, daughter of Mr James Bell, who predeceased him. They had no children. Those who enjoyed his friendship or acquaintance cannot fail to remember his personality, and to recognise the aptness of Dr. Fairbairn's words. Blair-Bell was of the stuff from which great men are made, and he was a great man both in example and accomplishment.

CHARLES ANDERSON FERGUS, L.R.C.P. Edin.

THE death is announced in his eightieth year of Dr. Charles Anderson Fergus, for many years medical officer for East Kilbride parish where the whole of his medical career was spent. He practised with his father, and within the memory of many he was always entitled "the young doctor," then he became popularly known as "Dr. Charles," and lived to be affectionately spoken of as "the old doctor." He had a particularly strong hereditary claim on the regard of the neighbourhood. His grandfather was ordained minister of the Relief church 140 years ago, while his father, Dr. James Fergus, who graduated in medicine 95 years ago, founded the medical practice in Kilbride immediately after qualification. Of Dr. James Fergus's two sons, the elder, who practised in Yorkshire, is still living at the advanced age of 88 years.

MURDO TOLME MACKENZIE, M.B. Edin.

Dr. Murdo Mackenzie, who died on Jan. 11th in his seventy-eighth year, had seen 50 years' service in the Scottish islands. He was the son of the factor of the MacLeod estate and was educated at Daniel Stewart's College and the University of Edinburgh, graduating as M.B., C.M. in 1880. He was early appointed medical officer for the whole parish of North Uist, and until recently had charge single-handed of the island and also of Grimsay, Heisker, and Berneray, but under the reorganisation of the Highlands and Islands service he became responsible only for the west side of North Uist. There he was parochial medical officer and M.O.II., surgeon to the Lockmaddy prison, and acted as sheriff substitute for Inverness-shire, of which county he was a J.P. He was also medical officer to the post office, and after

the war did considerable work under the Ministry of Pensions. He endured for most of his working life the great physical hardships of practice in the island district, and became an absolute repository of the physical and family stories of his whole environment, having been either publicly, professionally, or personally in contact with practically everybody. He had a fine record of service and his reputation is safe in the recollection of the people of North Uist.

THE LATE PROF. STARR JUDD

Edward Starr Judd was born in Rochester, Minn., on July 11th, 1878, and died on Nov. 29th, 1935, when on the way to address a meeting at Philadelphia. Having graduated at Minneapolis in 1902 he became an intern at St. Mary's Hospital, Rochester, and in the following year first assistant to Dr. C. H. Mayo, the remainder of his life being spent as a member of the Mayo Clinic. In 1918 he was appointed to the graduate chair of surgery in the University of Minnesota.

Prof. Grey Turner writes: "Those who know the Mayo Clinic will be very sorry to hear of the death of Edward Starr Judd while still on the good side of 60. At the time of my first visit to Rochester thirty years ago Judd was an able second to the brothers Mayo, and in fact those three constituted the sole surgical team of that day. He was even then doing a fair share of the operative work and appeared to be thoroughly familiar with all branches of surgery. From that time to his death, save for short vacations, he operated every day of the week except Sunday, and his lists seldom ran to less than six cases, so that in the course of his career he probably did more operations than any other surgeon.

"Judd was a first-rate all-round man, and though in recent years his work was mostly confined to the abdomen, he was never a specialist in any sense of the word. He was a beautiful steady operator, always the same, never fast never slow, and above all never put out or fussy. The patient always seemed safe in his hands, and many a spectator picked him out as *the* man to operate on those near and dear. But he was not only a renowned operator but a great doctor, and the investigation and care of his patients was thorough and sympathetic. His writings were not voluminous but were always practical and sound, and like his operative work showed good judgment throughout. In the clinic Judd was obviously an influence for good, and his earnest conciliatory manner must have been an enormous asset in such an organisation. He possessed the highest of all distinctions in that he was a *maker* of surgeons, and I have heard many now well known in the surgical world who have acknowledged this indebtedness to him.

"Judd was of a quiet, restful disposition, delighting in his work, in his home, and in loyalty to his chiefs, ever on his lips as 'W. J.' and 'C. H.' His one relaxation appeared to be duck shooting, but even that fascinating sport only lured him away from work for short periods. He will be missed far beyond his immediate circle."

In 1931-32 Prof. Judd was president of the American Medical Association.

ST. BARTHOLOMEW'S HOSPITAL, LONDON.—The Smithfield Benevolent Fund committee has raised £10,000 to establish visitors' rest rooms and a canteen at this hospital.

MEDICAL NEWS

University of Oxford

Radcliffe Travelling Fellowship.—An examination for this fellowship, which is of the annual value of £300 and is tenable for two years, will be held on Feb. 18th. Candidates must have passed all the examinations for the degrees of B.M. (not more than four years previously) and B.A. Further particulars may be had from the regius professor of medicine, University Museum, Oxford, to whom all intending candidates should send their names before Feb. 13th.

George Herbert Hunt Travelling Scholarship.—Applications for this scholarship, which is awarded without examination, are invited from graduates in medicine of the university of not more than five years' standing who wish to travel abroad for at least three months for the purpose of clinical study or research in medicine. Preference will be given to those who intend to become surgeons or general practitioners, and applications should be sent to the dean of the medical school, University Museum, before Feb. 24th.

University of Cambridge

On Jan. 25th the following degrees were conferred:—

M.D.—B. C. Thompson, C. H. Wrigley, and D. N. Roeyn Jones.

M.B. & B.Chir.—S. M. Davidson and K. C. Bailey.

M.B.—Wilfrid Warren.

B.Chir.—L. J. Bacon, T. L. H. Shore, G. N. St. J. Hallett, J. R. Kerr, J. R. G. Harris, A. G. Salaman, J. R. J. Winter, C. A. Dowding, Frank Stansfield, and R. D. Ewing.

Royal College of Surgeons of England

The Begley studentship will be awarded to the candidate who this year obtains the highest marks in the anatomical part of the examination in anatomy and physiology held by the conjoint examining board in March and April. The studentship is tenable for three years, and has an annual value of £20. Further information may be had from the secretary of the college, Lincoln's Inn Fields, W.C.

British Postgraduate Medical School

Six lectures on fractures will be given by Prof. Hey Groves on Fridays from Feb. 7th to March 13th, and four lectures on cerebro-spinal syphilis by Dr. Gordon Holmes, F.R.S., on Mondays from March 2nd to 23rd. Both series will be held at 2.30 P.M. at the school, and applications for tickets should be sent to the dean. Further particulars will be found in our advertisement columns this week.

Demonstrations of Contraceptive Technique

On Thursday, Feb. 6th, at 2.30 P.M., a demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs. Mario Stopes, D.Sc., and Dr. Evelyn Fisher at the Clinic for Constructive Birth Control, 108, Whitfield-street, London, W.1. Tickets will be issued to medical practitioners and senior students who apply in writing to the hon. secretary at the clinic.

British College of Obstetricians and Gynæcologists

The quarterly meeting of the council of the College was held on Jan. 25th in the College House, when Sir Ewen Maclean, the president, reported that a loyal address had been sent to H.M. King Edward VIII. He reported further that the outline of a scheme for a national maternity service had been submitted to the Minister of Health. The report of the investigation into the use of analgesics suitable for administration by midwives was passed.

The following were elected to the membership of the College:—

Alan John Stewart Lawson Boyd, South Africa; Mildred Isabel Ealing, London; Barton Gilbert, London; Stanley Henderson, Liverpool; Edwin Holmes, Hove; Charles Roy MacDonald, Sheffield; John Sinclair MacVine, London; Thomas N. MacGregor, Edinburgh; Stanley Devenish Meares, Sydney; Elizabeth Main Moore, London; Frederick Walter Gifford Nash, Bedford; John Gregory O'Donoghue, Melbourne; Patrick Playfair, London; Anthony Watson Purdie, Glasgow; Cleveland Patrick Scott, London; Edward Solomons, Dublin; William Ralph Winterton, London; Bryan Leslie Jeffreson, Leeds; Israel Goldberg, Cape Town; Presley Archer McLeod, Ontario; Cyril MacDonald Plumtre, Madras; and Harold Rowntree, Lahore—the four last-named in absentia.

Post-graduate Course in Orthopædic Surgery

A special course will be held at the Royal National Orthopædic Hospital, 234, Great Portland-street, London, W.1, from March 9th to 21st. Applications should be made to the secretary of the hospital.

Journées Médicales de Bruxelles

This congress will be held from June 20th to 24th under the presidency of Prof. Robert Danis. Further information may be had from the secretary of the meeting, Dr. R. Beckers, 141, rue Belliard, Bruxelles.

Physical Exercise and Education

On Tuesday, Feb. 4th, and on the following three days, at 6 P.M., Dr. J. Alison Glover, senior medical officer of the Board of Education, will lecture at Gresham College, Basinghall-street, E.C., on some aspects of exercise, physical education and swimming. The lectures are open to all.

The Psychological Clinic and Community Welfare

Four lectures on this subject will be held at the Liverpool Psychiatric Clinic (56, Bedford-street North) on Wednesdays from Feb. 5th to 26th at 5.15 P.M. Juvenile courts, probation work, patrol work, and industrial and vocational psychology are the aspects which will be discussed.

A Memorial to Prof. A. F. Dixon

A meeting of friends and colleagues of the late Prof. Francis Dixon was held in the Common Room, Trinity College, Dublin, on Jan. 24th, to consider the establishment of a suitable memorial to him. In the absence of the provost of the college the meeting was summoned by the vice-provost, Mr. W. E. Thrift, who presided over the deliberations. Several projects having been discussed, a general committee was appointed to forward the movement, and an executive subcommittee was requested to study and report on the most suitable form of memorial. Prof. J. W. Bigger is acting as honorary secretary and Mr. G. A. Duncan, F.T.C.D., as honorary treasurer.

Standard Blood Counting Apparatus

A committee of the British Standards Institution have prepared a specification for haemocytometer counting chambers and dilution pipettes. The institution is desirous that this draft should receive the widest possible consideration, so that the specification, when finally published, may command the greatest possible measure of agreement. A copy of the draft specification may be obtained, post free, on application to the Director, British Standards Institution, 28, Victoria-street, London, S.W.1, to whom suggestions for amendment of the draft may be sent. Any comments submitted will receive careful consideration when the draft is being revised for publication.

Association of Industrial Medical Officers

The second meeting of this association was held in the London School of Hygiene and Tropical Medicine on Friday and Saturday, Jan. 24th–25th, under the chairmanship of Dr. H. B. Trumper (Imperial Chemical Industries Ltd.), in the absence of Dr. Howard Mummery through illness. On Friday a discussion took place on Physical Standards in Industry, opened by Sir David Munro, secretary of the Industrial Health Research Board (whose address is summarised in a leading article on p. 265). He was followed by Dr. H. H. Bashford, chief medical officer to the Post Office. In the evening members dined together. On Saturday, Dr. T. O. Garland (Carreras Ltd.) read a paper on The Relation between the Industrial Medical Officer and the General Practitioner. He was followed by Dr. J. C. Bridge, chief medical inspector to the Home Office. Dr. Garland spoke of the importance of closer co-operation and contact between industrial medical services and other medical practitioners, and referred to the place of treatment in the industrial clinic. He also discussed briefly the position of the employee and employer in relationship to the industrial doctor. Dr. Bridge dealt with the relationship of the certifying surgeon to the industrial medical officer.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Feb. 4th.

Orthopaedics. 5.30 P.M. (Cases at 4.30 P.M.) Mr. Eric Lloyd: A Director for the Insertion of the Smith-Petersen Nail in Collum Femoris Fractures. Mr. E. P. Brockman: 1. Osteochondritis of the Head of the Radius. Mr. W. H. Ogilvie: 2. Deformity of Spine and Hips. Mr. T. T. Stamm: 3. Occupational Deformity of the Hands.

Pathology. 8.15 P.M. (department of pathology, Medical School, St. Thomas's Hospital, S.E.). J. Bamforth: 1. Carcinoma of Thymus with Malignant Cells in Sputum. 2. Teratoma of Testicle with Positive Friedman Test. 3. Endotheliomatous Change in a Uterine Fibroid. C. L. G. Pratt: 4. Effect of Toxins on Electrocardiograms of Animals. 5. Method of Constant Intravenous Injection in Anaesthetised Animals. J. St. C. Elkington: 6. Actinomycosis of Brain and Meninges. 7. Hamangioma of Spinal Cord with Syringomyelia. 8. Oligodendroglioma of Third Ventricle. J. O. Oliver: 9. Gonococcus Ecto-antigen. 10. Hemochromatosis with Analysis of Organs. 11. Widespread Hepatic Thrombosis. 12. Pulmonary Thrombosis with Calcification of Clot. N. R. Barrett: 13. The Examination of New Growths by the Wet Film Method. D. C. L. Derry: 14. Plasma-celled Myelomatosis. 15. Chronic Inflammatory Lesion of the Lung with Complete Necrosis of Spleen. 16. Rheumatic Carditis Associated with the Presence of Bacteria in the Mitral Valve. C. H. Wrigley: 17. Demonstration of Particles of Malignant Growths in Sputum.

WEDNESDAY.

History of Medicine. 5 P.M. Prof. Alexander Haddow: Historical Notes on Cancer from the MSS. of L. W. Sambon.

Surgery. 8.30 P.M. Sir W. Dalrymple-Champneys: The Sterilisation of Surgical Catgut (cinematograph).

THURSDAY.

Tropical Diseases and Parasitology. 8.15 P.M. Prof. R. T. Leiper: The Crustacea as Helminth Intermediaries. Dr. B. G. Peters: Some Recent Developments in Helminthology.

FRIDAY.

Otology. 10.30 A.M. (Cases at 9.30 A.M.) Mr. W. Stirk Adams, Mr. T. E. Cawthorne, and Dr. M. Mitman: Value of Radiology in Disenses of the Ear.

Laryngology. 5 P.M. (Cases at 4 P.M.) Mr. Maxwell Ellis: The Mechanism of Bronchial Movements and the Naso-pulmonary Reflex.

Anaesthetics. 8.30 P.M. Dr. I. W. Magill: Anaesthetics in Thoracic Surgery, with Special Reference to Lobectomy.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, Feb. 7th.—8.30 P.M. (De Vere Hotel, Kensington), Dr. Geoffrey Evans and Mr. Hamblen Thomas: Epistaxis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

MONDAY, Feb. 3rd.—5 P.M., Mr. A. M. Boyd: The Investigation of Peripheral Vascular Disease.

WEDNESDAY.—5 P.M., Mr. H. Osmonde Clarke: Injuries of the Carpal Bones.

FRIDAY.—5 P.M., Mr. F. H. Bentley: Wound Healing in vitro. The Interrelation of Epithelial and Fibrous Tissue Growth. (Hunterian lectures.)

GRESHAM COLLEGE, Basinghall-street, E.C.

TUESDAY, Feb. 4th, and 5th, 6th, and 7th.—6 P.M., Dr. J. Alison Glover: Some Aspects of Exercise, Physical Education and Swimming.

UNIVERSITY OF LONDON.

WEDNESDAY, Feb. 5th.—3 P.M. (London School of Hygiene, Keppel-street, W.C.), Col. L. W. Harrison: Venereal Disease.

FRIDAY.—11 A.M., Mr. H. E. Mudge, D.Sc.: Nutrition.

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.

FRIDAY, Feb. 7th.—2.30 P.M., Prof. Hey Groves: Fractures (first of six lectures).

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.

WEDNESDAY, Feb. 5th.—4 P.M., Mr. W. H. Ogilvie: Carcinoma of the Tongue.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.

TUESDAY, Feb. 4th.—5.30 P.M., Dr. T. F. Cotton: Rheumatic Carditis.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.

TUESDAY, Feb. 4th.—5 P.M., Dr. J. E. M. Wigley: Tuberculosis Cutis.

THURSDAY.—5 P.M., Dr. G. B. M. Heggs: Some Affections of the Skin of the Foot.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

WEDNESDAY, Feb. 5th.—2 P.M., Mr. Denis Browne: Empyema. 3 P.M., Dr. W. W. Payne: Vitamin Deficiency as a Predisposing Factor in Infection.

Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Feb. 3rd.—3.30 P.M., Dr. Hinds Howell: Neurosyphilis (II).

TUESDAY.—3.30 P.M., Dr. Critchley: Cerebral Vascular Disease (II).

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Dr. Carmichael: Myopathic Diseases.

FRIDAY.—3.30 P.M., Mr. Elmquist: Demonstration of Re-educational Methods.

Out-patient clinic daily at 2 P.M.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Feb. 3rd.—10 A.M., Medical wards and skin clinic. 11 A.M., Surgical wards. 1.30 P.M., Gynaecological wards. 2 P.M., Surgical wards, gynaecological and eye clinics.

TUESDAY.—10 A.M., Medical wards. 11 A.M., Surgical wards. 2 P.M., Throat clinic. 4.15 P.M., Mr. Woodd Walker: Derangements of Knee-joint.

WEDNESDAY.—10 A.M., Children's ward and clinic. 11 A.M., Medical wards. 2 P.M., Eye clinic. 4.15 P.M., Lecture on anaesthesia.

THURSDAY.—10 A.M., Neurological and gynaecological clinics. 2 P.M., Eye and genito-urinary clinics.

FRIDAY.—10 A.M., Skin clinic. Noon, Lecture on treatment. 2 P.M., Throat clinic.

SATURDAY.—10 A.M., Surgical and children's clinics, medical wards.

Operations, medical and surgical clinics daily at 2 P.M. The lectures at 4.15 P.M. are open to all medical practitioners without fee.

ST. JOHN CLINIC, Ranelagh-road, S.W.

FRIDAY, Feb. 7th.—4.30 P.M., Mr. L. Attkins: Oral Sepsis in Relation to Physical Disease.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 3rd, to SUNDAY, Feb. 9th.—ST. JOHN'S HOSPITAL, 5, Lisle-street, Leicester-square, W.C. Afternoon course in dermatology (open to non-members).—ST. MARKS' HOSPITAL, City-road, E.C. All-day course in proctology.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. All-day course in neurology.—ST. JOHN CLINIC AND INSTITUTE OF PHYSICAL MEDICINE, Ranelagh-road, S.W. Sat. and Sun. course in physical medicine.—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. Tues., 8.30 P.M., Mr. A. J. Cokkinis: Intestinal Obstruction. Thurs., 8.30 P.M., Mr. T. Holmes Sellors: Thorax.—Courses are open only to members and associates of the Fellowship.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.

WEDNESDAY, Feb. 5th.—4 P.M. (St. James' Hospital, Ouseley-road, S.W.), Dr. C. E. Lakin: Demonstration of Medical Cases.

LEEDS GENERAL INFIRMARY.

TUESDAY, Feb. 4th.—3.30 P.M., Mr. Flint: Demonstration of Cases.

LEEDS PUBLIC DISPENSARY.

WEDNESDAY, Feb. 5th.—4 P.M., Dr. H. H. Moll: Minor Allergic Diseases—Hay-fever, Urticaria.

UNIVERSITY OF DURHAM.

SUNDAY, Feb. 9th.—10.30 A.M. (Newcastle General Hospital), Dr. F. J. Nattrass: Medical Ward Visit.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, Feb. 5th.—4.15 P.M. (Royal Hospital for Sick Children), Mr. Alexander MacLennan: Orthopaedic Cases.

Appointments

BLAIR, L. G., M.R.C.S. Eng., D.M.R.E., has been appointed Specialist Radiologist at the Dagenham Sanatorium.

KELLNER, ANDREW, M.D. Leipzig, L.M.S.S.A., Hon. Assistant Physician to the London Homeopathic Hospital.

LYON, D. MURRAY, M.D., F.R.C.P. Edin., Principal Medical Officer of the Scottish Widows' Fund and Life Assurance Society.

MACLEOD, DONALD, F.R.C.S. Edin., Clinical Assistant at All Saint's Hospital for Genito-urinary Diseases, London.

SLATER, EFFIE, M.B. Lond., D.O.M.S., Assistant Medical Officer to the Education Committee of Wolverhampton.

Medical Referee under the Workmen's Compensation Act, 1925: PERCIVAL JOHN HAY, M.D., of Sheffield, for all County Court Districts at present comprised in Circuits Nos. 13 and 18, with a view to his dealing with ophthalmic cases.

Certifying Surgeons under the Factory and Workshop Acts: Dr. OLIVE G. COLDICOTT (Abergavenny, Monmouth); Dr. W. E. FAULKNER (Alva, Clackmannan); and Dr. J. H. ALLAN (Chorley, Lancs).

Dr. J. B. Albury has been appointed a member of the legislative council of the Bahama Islands.

Dr. D. C. Norris (Inner Temple) and Dr. F. Collar (Middle Temple) have been called to the Bar.

NOTES, COMMENTS, AND ABSTRACTS

THE PSYCHOLOGY OF
INTERNATIONAL RELATIONS*BY WILLIAM BROWN, D.M. Oxon., D.Sc.,
F.R.C.P. Lond.WILDE READER IN MENTAL PHILOSOPHY, UNIVERSITY OF OXFORD;
LATE MAJOR, R.A.M.C., AND NEUROLOGIST TO THE
FOURTH ARMY, B.E.F., FRANCE

THE psychology of international relations, otherwise the psychology of peace and war, can be adequately discussed only on the basis of a scientific knowledge of the structure and working of the human mind. A number of questions open out: how war is possible; how it can be carried on at all by civilised people; how peace can be achieved, this last only by a positive policy, never by *laissez-faire*.

Hobbes said that peace was merely an interval between wars, the wars being the real—meaning the normal—activity, and peace a breathing-space, a time when people are tired, disillusioned, and a little penitent. Those who take part in war customarily declare that when they have finished this business they will fight no more. The protestation has much the same value as that of the drunkard who exclaims as he lifts the glass to his lips that it is the last time.

Speaking as a psychologist, not as a politician, I am convinced that the latest war is not the last. In saying this I do not mean to be pessimistic, I am merely speaking as I would about a manic-depressive patient who, after a state of deep depression, passes into one of exaltation and feels that never again will his old symptoms return. With a patient like that we know that he will have another relapse sooner or later, and that no amount of suggestion or encouragement will make any difference. It is of no use telling him or his relatives that "All's well with the world"; a relapse is as certain as anything can be. In cases of manic-depressive insanity or the milder cyclothymia, as in other forms of psychoses as distinct from psychoneuroses, a radical cure has not been found. No psychotic has ever yet been cured by psychotherapy as such, although psychotherapy and psychology in general have enabled us to gain a deeper insight into the psychotic's state of mind, and sometimes to ameliorate the condition. We may cure or improve the hysteric, the psychoneurotic, but the psychotic still escapes us—although improvement, and sometimes spontaneous recovery, may occur.

So it is with war and peace. We cannot pretend as psychologists that a solution has been discovered at present. All we can do is to go on and disentangle the various forces which are at work to produce war. The causes of war are numerous, and many of them seem to have little to do directly with human nature. The economic causes of war spring at once to the mind. According to some systems of practical economics wars are inevitable and must occur from time to time. Conflicts of interests exist between nations and may become so severe that an appeal is at last made to the *ultima ratio*, the final court of trial by brute strength.

Again it is necessary to make the psychologist's position clear. As a psychologist I am not advocating any particular system of economics as distinct from others. We psychologists feel some sympathy with the economists, for we are in the same boat. Psychology and economics are the two sciences about which the man in the street thinks he knows as much as the expert. He is not going to be informed about his own mind, for who should know his own mind better than himself? He knows all about economics too,

for does he not have to deal continually with credit balances and deficits? That is one reason why progress in these sciences is so slow.

Man's Reactions to His Mind

Deep down in the mind—in our "heart of hearts," as we say—we are aware of the struggle for existence, the desperate fight between man and man, family and family, nation and nation, for security, position, and power, a fight variously disguised, halted by compromise and mutual adjustment, but at times flaming into open war. Schopenhauer in one of his "Occasional Essays" likened human society to a number of hedgehogs that found themselves getting chilly in the winter and so got closer and closer together to keep one another warm, but as they drew closer their prickles hurt one another, and so they moved away and got cold again, and eventually by trial and error found an optimum distance from one another at which they could keep fairly warm and at the same time escape hurt. So it is with man in society. He finds it difficult to harmonise with others, and yet if he went "on his own" his life would be "nasty, brutish, and short," to quote Hobbes's phrase, and so coöperation to a certain extent is forced upon him.

That, of course, is not a very close analogy, because society is not a matter of deliberate social contract, but has grown in relation to the needs of individuals, and individuals have never existed by themselves, but always within some system or family, and thus their social instincts and their ego instincts have developed *pari passu*. We cannot deduce the social behaviour of man from his purely individual behaviour, and, in fact, there is no such thing as purely individual behaviour because man is always acting as a member of some group and generally as a member of a number of groups simultaneously. It is not that psychology deals with the individual man while sociology and anthropology and other sciences deal with his social relations. At every point the individual is reacting to the society to which he belongs.

A purely economic theory of the cause of war might have a corresponding psychological theory, very simple, and therefore inadequate—namely, that man gets annoyed when his interests are threatened, irritated when his will to live is thwarted, economic difficulties make him angry, and when his misfortunes and the reason for them are declared to him by some demagogue he may in his irritated state become pugnacious and ready to fight. That theory is simple, as I have said, but very inadequate, because it takes practically no account of the structure of the mind. The individual mind has developed through countless generations from the most primitive condition with reference to a very real struggle for existence. We must accept in its general outline the Darwinian theory of natural selection and the survival of the fittest, for the mind as for the body. But although the mind has developed to a certain degree and it is possible for coöperation to supplement competition, and for man to become more and more coöperative and less and less competitive, nevertheless he still carries with him tendencies towards more primitive forms of mental reaction such as were appropriate to the early stages of national and social evolution, but are not so obviously appropriate now.

Primitive Urges

We observe this very clearly in criminal behaviour. A great deal of such behaviour is a relapse or a regression to a more primitive reaction of the organism. The murderer is not always someone whose reactions to life have been perverted, but often someone who, through disease of the nervous system or developmental degeneration, perhaps transmitted from parent to child, resulting in weakness of mental and nervous control, reacts as his primitive ancestors

* A paper read at the inaugural session of the Fourth Biennial Conference on Mental Health held in the Central Hall, Westminster, on Jan. 23rd, 1936.

ages ago reacted in an environment where such reactions would be accounted normal. He wants a man's watch, and the most direct method is to kill the owner. He yearns for the taste of roast pig, and so he burns down the house. Many of these severe cases of criminality resist every type of treatment, punitive or reformatory, because they are themselves primitive in this particular direction. In some ways they are a reversion to type, a "throw back" to a much earlier level of evolution.

All this means that civilised man, the modern *Homo sapiens*, carries with him possibilities of behaviour that are appropriate to the earlier stages of mental development, but are customarily held in check or superseded by more developed methods of reaction. On analysis one finds that most people who are regarded as normal still retain far down in their unconscious mind—that is, on the primitive levels of mentality—tendencies that were appropriate in the early stages of human development but are no longer allowed to be dominant.

One of these primitive tendencies is that of self-preservation, present in all of us, but held in check by higher considerations; in part such urges have been not destroyed or neutralised, but directed in the course of evolution to higher social and cultural ends. But a good deal of the old urge remains at its most primitive levels, even in the most highly developed man, so that in certain conditions of great danger, especially when accompanied by ignorance of what exactly is happening, the urge for self-preservation may leap forward with overwhelming force, and he may take refuge in panic-stricken flight, to his own great disgust afterwards. It is the same with the urge not only to preserve our lives but to assert ourselves, to extend and enlarge our powers. This again may be held in check by various mental mechanisms of later development, by the grace of modesty, by self-criticism, by consideration for others, by a regard for what is decent, even by a sense of proportion in things, and, which follows from it, a sense of humour; yet nevertheless, deep down in the mind, some of this self-assertive tendency remains, and given the occasion may blaze out very much in its original form. This, again, can happen in the most highly developed of men.

One of the many occasions when these primitive tendencies can show themselves uncensored and unreproved is in a great mass movement where the individual feels the safety and security of the crowd around him, all thinking in the same way, and his sense of responsibility to himself is greatly lightened. He does not deliberately give way to more primitive tendencies, but those primitive tendencies are always ready to come forward and manifest themselves through more complicated civilised behaviour. They are like a charge of electricity suddenly short-circuiting a delicate installation, overcoming all resistances, and lighting the landscape with a lurid flame. Thus a crowd may fall into a panic and in such a state take the slightest occasion for action utterly out of proportion to the circumstances. It may when aroused spring savagely like a tiger without reck or consideration even for its own safety. Yet in that crowd, moved by the same impulses and intent on the same wild course, may be men who individually would never dream of acting in that way. That situation was recognised long before any analytic work had been done upon the mind. The crowds of the French Revolution, for example, and the excesses which they committed were the subject long ago of psychological study.

Mass Psychology

The possibility of mass mental reactions or mass psychoses has an obvious bearing upon the problem of war and peace, but the deeper analysis of the mind in recent times inaugurated by Sigmund Freud has shown to how great an extent mental forces can continue to manifest themselves in an unconscious form, even while the conscious mind is fully alert and apparently in full control. All these forces that

come up so obviously in mass movements are working also in the individual mind and showing themselves in distorted forms. Even mental reactions that the majority of people would recognise as perfectly normal and appropriate to the circumstances can by analysis be traced back to still more primitive tendencies from which they derive their energy. It is as if a person who belonged to a wealthy family used the leisure that his inherited wealth made possible to become highly cultured, deeply read, artistically appreciative, while yet the money which enabled him to do this came from the labour of many of his own species, hewing minerals from the bowels of the earth at great toil and risk and with little reward. The example that springs to the mind is that of Greek culture during the golden age in Athens, a culture which was, of course, founded upon slavery. Slavery was justified even by Aristotle. The arguments are familiar, they are biased, and can be used in different ways to point to different conclusions. I am using it here only as an analogy, and indeed as an analogy it does not completely hold, because the forces in the unconscious in our highly developed cultural life are not in themselves good or bad, they just represent biological or mental energy.

Among them are these primitive forces of self-preservation and self-assertion. Both in their measure are needed. Unless we are able to preserve our lives we shall do no good to anyone. Self-assertion, too, is obviously good in a general sense, though it can be directed in such a way as to be a curse to everyone concerned. It is all a matter of direction, and in the cultured life it is directed adequately. With that cultured outlook on life these fundamental forces have to be kept at bay, under control, used as the powers of nature are used in an industrial civilisation. Used in a different way they may result in institutions and forms of thought which are irreconcilable with ultimate peace between individuals or between nations. It comes to this, that he who wills the means wills the end. A certain outlook on life, a certain direction or misdirection of the internal forces may involve ultimately such a conflict as can only be settled by an appeal to force.

The Rule of Law

It is often said that war could be prevented in the same way as duelling has been prevented, by legal process. Might not the appeal to force as between nation and nation be brought to an end if it were declared illegal? But it must be remembered that a law, although ultimately it may be in harmony with the moral outlook of the great majority of individuals, needs force to sustain it. In separate communities it is sustained by police. An international law binding the nations would need to be supported by force at the present stage of human evolution. From a psychological point of view it seems to me an obvious implication that we need a supernational institution with adequate force at its disposal to support the decisions of international law. That is not within the bounds of practical politics at the present time. No nation would surrender its sovereignty to a super-state. Such quixotism is not to be found now upon the earth. The only alternative to this—I do not want to lecture on the subject, but to consider it only in relation to psychology—is a *pis aller* or second best, a system of collective security through the League of Nations.

For that to be really successful it should be universal. The League of Nations must include the whole world, because peace is a matter which affects the whole world, especially in view of the rapidly extending lines of communication and the physical, economic, and cultural contacts of all countries. A true League of Nations must include every nation, and then the principle of collective security may be capable of being maintained and the primitive passions of separate nations held in leash. But as things are at present there is no immediate prospect of a complete League, and to the extent to which it is incomplete, psychologically speaking—and again

I am not speaking as a politician—its prospects of success are greatly diminished. It is even a question whether, in such a situation, it is not better to recognise the difficulties, and seeing that there is not an adequate force at the disposal of the League to impose its decisions, to keep those decisions as expressions of moral opinion, otherwise the League may involve more fighting and not less. But the more courageous way is to organise economic (as distinct from military) sanctions to the utmost of which the nations now members of the League are capable, and thus to bring *forcibly* home to an aggressor the collective moral disapprobation of his aggression.

Mobilisation of the Unconscious

It may be asked how it is possible for any individual who has enjoyed the benefits of modern culture and has acquired self-control to be brought to such a state of mind that he can kill another with whom he has no personal quarrel. In the quiet and even friendly atmosphere of the laboratory a man may, in his scientific enthusiasm, concern himself with aeroplanes and armament of various kinds, forgetting the use to which they are to be put; but how is it possible for him to fire the guns, explode the munitions, drop the bombs, release the poison gas, knowing that the result will be the killing and maiming of his fellow-creatures? In other words, how is it possible for anyone to take part in war? That is a psychological problem which each of us must put to himself. In the last war there were a number of people who refused to have anything to do with it. They were all classed together as conscientious objectors, though in fact the motives behind their refusal differed along a wide range. In fact, they had only this in common, a strongly individualistic turn of mind, and indeed it needed to be strong to withstand the tremendous mass suggestion which was surging around them.

But the great majority of people were swept along on the wave of popular feeling, and, I suppose, in the circumstances of 1914 as they presented themselves to the normal mind at that time, with all that people learned or were told of the events preceding the outbreak and those of the first months of the war, active participation in or support of the war seemed to be called for by the reason and conscience of the individual as well as by the authorities of the State. The unconscious was being mobilised at the same time as the mobilisation of the army and navy.

Nevertheless, I think it may be stated that if the individual man was fully aware of all the unconscious forces at work his participation in war would at any rate be more hesitating, his mind more a prey to misgiving. Here let me say I am not approaching the subject of participation or non-participation from the point of view of ethics or religious conviction. Those are the ultimate court of appeal, but we are not dealing with them at the moment. It is purely a question of the facts at our disposal and appropriate action on them. My contention is that we have not all the psychological facts at our disposal when we endeavour to sum up this question of our duty. If the psychological panorama were cleared of the smoke screen we should not at all events have that terrible contradiction whereby opposing peoples take up arms against one another to the glory of God, each appealing to Him for victory.

Forces on Leash

All this, I know, is a platitude, but it has to be mentioned in order that we may face up to the psychological problem. The unconscious urges which are demanding satisfaction have to be remembered. These are not just skeletons in the cupboard, they are very live and potent forces. The tiger is there, and the wolf, and the jackal, and the snake, and we must not forget the donkey. These are at all ordinary times held in check by our conscious aims and purposes, and in general by our culture, our

sense of what is due to others and admirable in ourselves. But the working of these unconscious forces can distort our moral judgment, so that for example during the last war we had quite kindly and well-educated people uttering such sentiments as that "the only good German is a dead German," though this became less pronounced as the war went on and weariness and disillusionment developed. We have to ask ourselves the question, what strange mentality settled upon them that they could deny all that culture and social contacts had brought them and be as bloodthirsty as their primeval ancestors? It is true that the Germans had invaded Belgium; that and other things were fuel for the eager fire. Behind it all was the deep conviction that a man must be ready to fight for his king and country and to preserve the life and honour of his own.

Those were the motives on the surface, and it is true that once war had begun there was a certain responsibility upon the shoulders of everyone to see that it was prosecuted with the utmost efficiency.

"Theirs not to reason why,
Theirs but to do and die"—

and this they did, acting according to whatever plans were devised by the higher command. The whole nation was working as a nation on the principle of self-preservation. The individual was drawn up into the national life in a way which certainly that generation had never known before. His unconscious had the texture of the unconscious of all the other members of the nation.

The same thing happens in times of revolution. The leader, so called, at such times is really the man who stands for the unconscious of all the people whom he leads. People have the leaders they deserve or demand. The leader is the man who satisfies not only their conscious demands but their unconscious urges. But that is a thing which is always overlooked and will continue to be overlooked by the mass of educated people for a long time to come.

Propaganda and Proper Geese

It is seen fairly clearly now that if peace is eventually to be achieved economic science must give of its best, and what it gives must be acted upon; but it is not seen with equal clearness that psychological science must also give of its best, and that what it gives must be acted upon. Up to now there has been a good deal of perverted use of psychology in relation to war and peace—I refer to its use in connexion with propaganda. As soon as war breaks out no doubt it is morally right to use propaganda on each side to the utmost extent. It is the propaganda that takes place before war that is so devilish. By propaganda I mean here, to use a simple word, lying, the distortion of facts. Such propaganda is successful enough, given the proper geese, the people ready to accept the lies or the false emphasis. Propaganda for ulterior motives makes it difficult even for the best educated individual to arrive at the facts. He seeks for them and does not get them, whatever newspaper he takes. One of the great needs of the world is for complete truthfulness, but lying and chicanery are part of the very art of war.

As an illustration of how psychological motives in war may work, in another country it was said that in the last war they had been brought in to support financial interests, the interests of people who had invested heavily and risked a great deal of wealth in support of other nations engaged in that war. I am not saying that that was true, but only that if it were true we should have a primitive motive—namely, the desire for gain, or the desire to escape financial ruin—supporting and energising more lofty moral considerations.

But if it is possible, as indeed it is, on the fully conscious plane to have deliberate mis-statements and misdirection and deception and appeal to prejudice, and fixed ideas about the duty to fight, and the slogan "My country right or wrong,"—if

that is possible on the purely conscious level, how much more danger must there be in appeals directed to unconscious forces in the mind? I have spoken already of the instinct of self-assertion. The desire for power and prestige goes hand in hand with the sense of the importance of one's family, or college, or country, and so from the depths of the unconscious there is a continuous line or channel of energetic mental development. Such self-assertion can be very rigid and intractable. It can be distorted in all sorts of ways and disguised in scarcely recognised forms. One of the most overwhelmingly successful ways of disguising it from ourselves is to moralise it, to say that we have a duty to this, that, or the other, and to let that sense of duty reinforce what is, when uncovered, the working instinct of self-assertion or desire for power of a ruthless kind—ruthless, I say, because it arises from some primitive state where the individual neither knew nor received pity.

Aggression pure and simple in the unconscious is a primeval factor, the kind of thing that enables the soldier to kill his enemy when he "sees red." The word "sheep" has sometimes been applied to the soldier type of mind, but there is something much more positive than that about it. I am well aware, of course, that what I am saying is incomplete. On the other side there is the desire, equally fundamental, for fellowship, for love. It is from the refusal of love that a great deal of aggression springs. The little child wants to be loved and is ready to love, but if it does not receive love from its parents it is likely to become an intractable child, hostile and aggressive. Such aggressiveness is not primitive, it is secondary to the denial of love.

I feel that it is the same between nations. One nation wishes the friendship of another; it would rather be the ally of the other than its enemy. But if its overtures are rejected a revulsion of feeling may take place such as that which overwhelms the scorned lover. There is thus a primary aggressiveness which comes out in battle and murder, but there is also a secondary aggressiveness which is very much more widespread and can manifest itself in its own way. There is the further danger in the situation that the primitive tendency to self-sacrifice, to injure oneself, may, when linked up with the ideal of national duty, supply a new fund of energy, and thus bring about war or keep a war going after it has broken out, and the cunning propagandist realises this and appeals to that very sentiment.

All these are factors which provoke and sustain war. I hope I have made it clear in the compass of a short address how much dangerous and explosive material there is which will have to be dealt with and cleared out of the way before peace can be ensured. It is rightly said that moral disarmament must precede material disarmament, but even before moral disarmament there must be a psychological assessment not only of those "inward parts" which, on the highest of all authority, may be "full of ravaging and wickedness," but also of still more deep-seated or primitive mental tendencies that in themselves are neither moral nor immoral.

NEW PREPARATIONS

MULTIVITE PELLETS.—In presenting their new chocolate-covered pellets, containing vitamins A, B₁, B₂, C, and D, the British Drug Houses Ltd. (London, N.1) quote a statement that "the interest which vitamins hold for the physician is not alone in their relation to certain well defined diseases . . . but rather in the fact that chronic vitamin deficiency produces numerous vague, borderline states of ill-health which often puzzle the physician and disable the patient." It is impossible, they say, to ensure that the normal daily dietary under modern conditions is rich in the necessary vitamins, and they mention anorexia, gastric distension, constipation, nervous disorders, dental decay, certain forms of

anæmia, and a feeling of being "out of sorts" as possible consequences of slight but general vitamin deficiency. Multivite Pellets have been made in response to a demand for a well-balanced vitamin concentrate which would be acceptable to adults and convenient for use in private practice and among hospital patients and out-patients. Each contains vitamin A 3000 international units, vitamin C 100, and vitamin D 600, with vitamin-B complex equivalent to 2.0 grammes of distillers' yeast. The suggested dose is for children 1-2 pellets daily and for adults 2-4. Samples are obtainable on application.

HEWSOL is described as a non-poisonous, non-corrosive germicide consisting of a pine oil treated by a special process and combined with a neutral soap so as to give a perfect emulsion when mixed with tap-water in the proportions recommended. It may be used undiluted on dressings applied to wounds, but as a general lotion 5-8 per cent. solutions are suitable. Apart from abrasions and cuts it may be used for douches, baths, and disinfectant sprays and for washing contaminated linen; its destructive action on cultures of *Bacillus typhosus* (Rideal-Walker coefficient) is stated to be five times that of carbolic acid. The proprietors, Messrs. C. J. Hewlett and Son, Ltd. (35, Charlotte-street, London, E.C.2), claim in addition that Hewsol is non-staining, non-irritating, free from cresol and xylene derivatives, and economical in use. It has a pleasant smell.

USES of ACRIFLAVINE.—The Boots Pure Drug Company Ltd. (Nottingham) have issued an interesting booklet describing the properties and many uses of the acridine antiseptics, with special reference to the Boots preparations of acriflavine, neutral acriflavine (euflavine), Acriflavine Emulsion, Burnol Acriflavine Cream, and proflavine. An enclosure is devoted to the use of acriflavine derivatives in gonorrhœa, where they are not only employed for local irrigation but also—with reservations—administered by mouth or by injection. Acriflavine Emulsion is recommended particularly as a dressing for wounds, septic conditions, burns and scalds, and ophthalmic inflammation or injuries.

SALICIN.—This drug, a glucoside obtained from willows and poplars, introduced as an anti-rheumatic in 1874, has suffered partial eclipse by sodium salicylate and allied compounds. To show that this eclipse is undeserved the three manufacturers in Great Britain (J. F. Macfarlan and Co., 32, Bethnal Green-road, London, E.1; T. and H. Smith Ltd.; and Whiffen and Sons, Ltd.) have prepared a statement of the value of salicin in medical practice and offer to supply samples of powder or tablets. They claim that it has none of the depressing or irritant effects of salicylates and that clinical experience has proved its usefulness in the treatment of influenza and rheumatism, and also of psoriasis and other skin diseases.

THE ALFRED EICHHOLZ CLINIC

THE Alfred Eichholz Clinic, 204/206, Great Portland-street, London, W.1, has issued a further edition of its handy scribbling pads, on the covers of which are depicted scenes from medical history. The latest is a reproduction from the well-known picture in Barber Surgeons-Hall, of Sir Charles Scarborough, first physician to Charles II., James II., and William III., and Edward Arris, serjeant-surgeon to Charles II.

NORTH HERTFORDSHIRE AND SOUTH BEDFORDSHIRE HOSPITAL, HITCHIN.—The Duchess of Gloucester opened a new men's ward and a new children's ward at this institution on Jan. 17th. The extensions cost £15,000 and are the first completed part of a £35,000 scheme. Nearly £900 in purses was presented to the Duchess. The children's ward is to be known as the Gloucester ward.

Vacancies

For further information refer to the advertisement columns

Aldrich Blake Travelling Scholarship.—200 guineas.
Ashton-under-Lyne District Infirmary.—H.S. At rate of £150.
Barbados General Hospital.—Sen. Res. Surg. £150.
Bath, Royal United Hospital.—H.S. At rate of £150. Also Hon. Med. Reg.
Beckenham, Bethlem Royal Hospital, Monks Orchard.—Jun. Asst. Phys. £350.
Bexley Urban District Council.—M.O.H. £800.
Birmingham City, Maternity and Child Welfare Dept.—Temp. M.O. £10 per week.
Birmingham Maternity Hospital.—Res. M.O. and Reg. £200.
Birmingham, Queen's Hospital.—Bacteriologist and Clin. Pathologist. £600. Also Res. Surg. Reg. £100.
Blackburn Royal Infirmary.—Res. Surg. O. £250. Also H.S. £175.
Bradford Royal Infirmary.—H.S. At rate of £135.
Bruton Clinic for Rheumatism and Allied Diseases.—H.P. At rate of £200.
Cambridge, Papworth Village Settlement.—H.P. £200.
Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.
Canterbury, Kent and Canterbury Hospital.—H.P. At rate of £125.
Colchester, Royal Eastern Counties' Institution for the Mentally Defective.—Asst. M.O. £350.
Cowenry and Warwickshire Hospital.—Res. Cas. O. £125.
Deusbury and District General Infirmary.—Sen. H.S. £200.
Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose, and Throat Depts. £175.
Downpatrick, Down Mental Hospital.—Jun. Asst. M.O. £300.
Dutwich Hospital, S.E.—H.P. At rate of £120.
East Ham Memorial Hospital, Shrewsbury-road, E.—H.P. At rate of £150.
Edmonton, North Middlesex County Hospital.—Jun. Res. Asst. M.O. At rate of £250.
Egyptian Government.—Director of Lunacy Division in P.H. Dept. L.E. 1020 to L.E. 1200.
Hull City Hospital for Infectious Diseases, Cottingham.—Res. M.O. £350.
Hull Royal Infirmary.—Second Cas. O. At rate of £150.
Infants Hospital, Vincent-square, Westminster.—Res. M.O. £300. Also two Physicians to Out-Patient Dept.
Lambeth Hospital, Brook-street, S.E.—Asst. M.O. £350.
Leeds General Infirmary.—Hon. Asst. Phys. £1000.
Leeds University.—Chair of Physiology. £1000.
Liverpool Hospital for Consumption and Diseases of the Chest.—Res. M.O. £150.
London Hospital, E.—Medical 1st Asst. and Reg. £300.
London Lock Hospital, Harrow-road, W.—Surg. Reg. to Dean-street Male Lock Hospital. £100.
Middlesbrough County Borough.—M.O.H. £1100.
Middlesex Hospital, W.—Fracture and Orthopaedic Registrar. £300.
Mill End Hospital, Bancroft-road, E.—Asst. M.O. £350.
Newcastle-upon-Tyne, Hospital for Sick Children.—Res. Surg. O. £250.
Northampton County Mental Hospital, Berrywood.—Second Asst. M.O. £450.
Nottingham Children's Hospital.—Res. H.S. At rate of £150.
Nottingham General Hospital.—Cas. O. At rate of £150.
Paddington Hospital, Harrow-road, W.—Asst. M.O. £350.
Perth Royal Infirmary.—Sen. H.S. £250.
Portsmouth City.—Visiting Consultant Obstetrician. £200.
Preston, Sharoe Green Hospital.—Sen. Asst. Res. M.O. Also Jun. Asst. Res. M.O. At rate of £200 and £100 respectively.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Res. Anaesthetist. At rate of £100. Res. Anaesthetist and Dist. Res. M.O. At rate of £90. Also Asst. Res. M.O. At rate of £80.
Queen's Hospital for Children, Hackney-road, E.—Res. M.O. At rate of £200. Also H.S. and Cas. O. Each at rate of £100.
Romford, Oldchurch Hospital.—Asst. Res. Radiologist and Jun. Res. M.O. Each £250. Also General Consulting Phys. £300.
Royal National Orthopaedic Hospital, 234, Great Portland-street, W.—Asst. Res. Surg. for Country Branch. £250.
Royal Naval Medical Service.—Eight vacancies.
Royal Northern Hospital, Holloway, N.—H.P. Also Obstet. H.S. Each at rate of £70.
St. Alfege's Hospital, Vanbrugh Hill, S.E.—Asst. M.O. £350.
St. Andrew's, Devons-road, E.—H.P. At rate of £120.
St. George-in-the-East Hospital, Raine-street.—Asst. M.O. £350.
St. John's Hospital, Lewisham, S.E.—Med. Reg. to Out-patients. 50 guineas.
St. Leonards-on-Sea, Buchanan Hospital.—Hon. Surgeon.
St. Peter's Hospital, Vallance-road, E.—Asst. M.O. £350.
Sheffield Children's Hospital.—H.S. At rate of £100.
Sheffield Royal Hospital.—Clin. Asst. to Ophthalmic Dept. Also Clin. Asst. to Ear, Nose, and Throat Dept. Each £300.
Shrewsbury, Royal Salop Infirmary.—Res. H.S. At rate of £160.
Shrewsbury, Salop Mental Hospital.—Asst. M.O. £350.
Stockport Infirmary.—H.S. and Cas. O. £150.
Stoke-on-Trent, North Staffordshire Royal Infirmary.—H.S. At rate of £150.
Waltham Abbey, Board's Isolation Hospital.—Res. M.O. £650.
West London Hospital, Hammersmith-road, W.—Half-time Pathologist. At rate of £300.
West Riding of Yorkshire County Council.—School Medical Inspector. £500.
Winchester, Royal Hampshire County Hospital.—Asst. Hon. Clin. Pathologist.
Windsor, King Edward VII. Hospital.—Hon. Asst. Surg.
Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—H.P. At rate of £100.

Births, Marriages, and Deaths

BIRTHS

BRADY-BIRKS.—On Jan. 26th, at the City of London Maternity Hospital, Hilda Kathleen Brady-Birks, M.Sc., M.B. Manch., wife of the Rev. S. Graham Brady-Birks, D.Sc., of Godmersham, Canterbury, of a daughter.
DUFFETT.—On Jan. 20th, at Plymouth, the wife of Edward C. Duffett, M.R.C.S. Eng., of a son.
GARLAND.—On Jan. 23rd, at Leeds, wife of Dr. Hugh Garland, of a daughter.
HADLEY.—On Jan. 16th, the wife of John A. Hadley, F.R.C.S. Edin., of Lincoln, of a son.
MORRISON.—On Jan. 17th, at Leeds, the wife of Dr. J. Morrison, Halifax, of a son.
ROWLANDS.—On Jan. 26th, at Wimpole-street, W., the wife of Dr. John Rowlands, of a son.
SANDELL.—On Jan. 23rd, at Wilbraham-place, S.W., the wife of David H. Sandell, M.D., F.R.C.S. Eng., of a daughter.
WHITTLE.—On Jan. 23rd, 1936, at Brookfield, Cambridge, to Phyllis (née Fricker), wife of Dr. C. Howard Whittle—a son.

MARRIAGES

DALRYMPLE SMITH—RILEY.—On Jan. 23rd, at St. Joseph's, Richmond, Yorkshire, Angus Dalrymple Smith, M.B., F.R.C.S. Edin., to Rowena, younger daughter of Mr. Herbert Riley, of Richmond, Yorks.
PASMORE—CALMAN.—On Jan. 22nd, at Kingston Vale, Dr. Stephen Pasmore to Dr. Jean Calman, daughter of W. T. Calman, C.B., D.Sc., F.R.S., and Mrs. Calman, M.B.
SANDEMAN—CUNNINGHAM.—On Jan. 22nd, at Perth, Charles Stewart Sandeman, M.B., Ch.B. Edin., to Eva Margaret, daughter of the late James Cunningham and Mrs. Cunningham, St. Andrews.

DEATHS

BLAIR-BELL.—On Jan. 25th, Prof. William Blair-Bell, M.D. Lond., F.R.C.S. Eng., F.C.O.G., West Felton, Shropshire, aged 64.
BROOKE.—On Jan. 15th, at Singapore, Gilbert Edward Brooke, L.R.C.P. Edin.
COLQUHOUN.—On Jan. 23rd, at a nursing-home, William Brooks Colquhoun, M.R.C.S. Eng., aged 76.
GWYNN.—On Jan. 20th, at Brighton, Edward Betton Gwynn, M.B. Edin., eldest son of the late Samuel Betton Gwynn, F.R.C.S. Eng., L.R.C.P., of Wem, Shropshire.
HARRISON.—On Jan. 24th, suddenly, at Worthing, Henry Leeds Harrison, M.B. Camb.
JONES.—On Jan. 20th, at St. Clears, South Wales, Valentine Llewellyn Watson Jones, M.R.C.S. Eng., in his 83rd year.
MAXWELL.—On Jan. 24th, at Yeomans, Wrington, Somerset, Herbert Bowen Maxwell, M.R.C.S. Eng.
MORRIS.—On Jan. 23rd, at Harrogate, Richard John Morris, C.B.E., M.D. Durh., aged 75.
SHEPPARD.—On Jan. 22nd, at Crockham Hill, near Edenbridge, Kent, Amy Sheppard, O.B.E., M.B. Lond., D.P.H. Camb., late of Harley-street, W.
N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE FOTHERGILL TESTIMONIAL FUND

THE following is the first list of subscriptions received in response to the letter published in the *British Medical Journal* and *The Lancet* of Jan. 18th

Helen Boyle (Hove), £50; Alfred Cox (London) and Donald Hall (Hove), each £20; A. C. Gemmill (Hove), £5; Donald Hall (Hove), second subscription, £10 10s.; Sir Ewen Maclean (Cardiff), C. E. S. Flemming (Bradford-on-Avon), A. H. Burgess (Manchester), W. McAdam Eccles (London), and J. W. Bone (Luton), each £5 5s.; H. G. Dain (Birmingham), £3 3s.; J. D'Ewart (Manchester), £1; G. Saunders (Kew), £1 1s.; W. E. Thomas (Ystrad Rhondda), £5 5s.; R. Whittington (Hove), 10s. 6d.; Sir Henry Brackenbury (Hendon), £5 5s.; P. Macdonald (York), £5; F. C. B. Gittings (Southsea), £1 1s.; E. M. Glynn (Whitby) (Liverpool), £2 2s.; H. M. Galt (Jersey), D. G. Greenfield (Rushden), A. T. Ross (Mevagissey), and N. E. Waterfield (Great Bookham), each £1 1s.; F. Radcliffe (Dedham), A. Forbes (Shelfield), and J. Hudson (Newcastle-upon-Tyne), each £2 2s.; P. B. Spurgin (London), £1 1s.; H. N. Fletcher (Hove), £10 10s.; G. C. Anderson (London), £3 3s.; Sir Farquhar Buzzard (Oxford), £5; R. C. Buist (Dundee), £5 5s.; A. Lyndon (Hindhead), and E. A. Starling (Tunbridge), each £1 1s.; Prof. J. W. Biggar (Dublin), £3 3s.; C. Gibson (Worthing), £1 1s.; Lancashire Local Medical and Panel Committee, £52 10s.; N. Bishop Harman (London), £5 5s.; S. A. Winstanley (Urmston), £1 1s.; and N. G. Horner (London), £3 3s. Total £262 14s. 6d.

Cheques should be made payable to the Fothergill Testimonial Fund, and addressed to the Treasurer, Fothergill Testimonial Fund, British Medical Association, B.M.A. House, Tavistock-square, London, W.C.1.

ADDRESSES AND ORIGINAL ARTICLES

MATERNAL MORTALITY IN HOSPITAL

A REVIEW OF 999 FATAL CASES IN THE GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL DURING TEN YEARS, 1925-34 *

By DUGALD BAIRD, B.Sc., M.D. Glasg., F.C.O.G.
VISITING OBSTETRIC SURGEON, GLASGOW ROYAL MATERNITY HOSPITAL

THIS investigation has been undertaken to test the impression that, although the maternal mortality for Scotland generally continues to rise, the death-rate in hospital is steadily falling. In 1930 big changes were made in the organisation of the Glasgow Royal Maternity Hospital and the staff was greatly increased. The results recorded in the five-year periods before and after these changes are here compared.

During the first five-year period, 19,134 cases were admitted with 542 deaths (28 per 1000), while during the second five-year period, 22,425 cases were admitted with 457 deaths (20 per 1000). There has therefore been a considerable fall in the death-rate during the last five years, despite the fact that the percentage of abnormal cases has risen from 62 to 65. Table I. contrasts the numbers and death-rates of some of the complications dealt with during the two periods.

TABLE I

Numbers and Death-rates of Complications during the Two Periods

Condition.	First five years.		Second five years.		Difference between first and second five years.
	No. of cases.	Mortality per cent.	No. of cases.	Mortality per cent.	
Hyperemesis ..	255	12.1	382	4.4	+127
Albuminuria ..	1162	2.7	1397	1.5	+235
Eclampsia ..	395	18.0	330	17.6	-65
Forceps, &c. ..	1260	4.3	1810	3.3	+550
Cæsarean section for contracted pelvis ..	424	3.0	699	2.0	+275
Failed forceps outside	190	16.3	236	13.1	+46
Craniotomy ..	226	11.0	147	7.5	-79
Abortion ..	3290	1.2	3219	0.6	-71
Placenta previa ..	406	13.0	487	7.5	+81
Accidental hæmorrhage ..	527	4.5	633	5.0	+106
Cardiac disease ..	345	10.4	606	6.4	+261

For further analysis the fatal cases have been grouped according to the condition for which the patient was admitted to hospital—unless she was admitted in labour or for some complication of labour, in which case they have been classified according to the cause of death.

TABLE II

Analysis of Fatal Cases

	1925-29.	1930-34.
Toxæmia ..	159	118
Sepsis ..	139	98
Shock ..	58	56
Hæmorrhage ..	104	107
Intercurrent disease ..	82	78

The comparison shows a notable fall in the number of deaths from toxæmia and sepsis in the second

five years, and this is in direct contrast to the finding of the Department of Health for Scotland, in their 1935 report, that the death-rate from those two causes is on the increase. Each group will now be dealt with in detail.

TOXÆMIA

Eclampsia.—During the first five years there were 395 cases of eclampsia with 71 deaths (18 per cent. mortality), and in the second five years 330 cases with 58 deaths (17.6 per cent. mortality). Hence there has been no striking improvement in the results of treatment of eclampsia, and we must look to prevention by strict antenatal care to reduce the incidence. In the first five-year period very little is known about the antenatal care received by the fatal cases. We do know, however, that 8 of them were being treated in the antenatal wards of the hospital for albuminuria. We know that in the second five years 40 per cent. of the cases had antenatal care, and in most of the others the antenatal supervision was poor. There were no deaths from eclampsia in this second period among women being treated in the antenatal wards of the hospital, but 7 of the fatal cases attended the out-patient department of the hospital and were later admitted with eclampsia. These 7 cases all occurred before the end of 1932, since when the antenatal supervision has been stricter and the importance of the fact that raised blood pressure may be the only pre-monitory symptom of toxæmia has been realised. In the years 1933 and 1934 there have been no fatal cases of eclampsia in patients under hospital supervision. This suggests that death from eclampsia can be avoided by intensive antenatal care. The following figures show, however, that eclamptic seizures still occur in patients under hospital treatment. During the years 1934 and 1935, 46 cases of eclampsia were admitted to one unit of the hospital, 7 of which were under hospital supervision. There were 6 deaths among 35 patients who had poor antenatal care or none (17.1 per cent. mortality), none in the hospital cases, and none in 4 who had good antenatal care outside. One of the hospital cases may be quoted.

Mrs. A., aged 22; first pregnancy, last menstrual period March 24th, 1934. On Dec. 24th she was sent to the out-patient department of the Maternity Hospital from a local authority clinic because of slight œdema and headache of two weeks' duration. Blood pressure 160/108; urine clear. Hospital treatment was refused, but on Dec. 31st she was admitted to hospital after persuasion; B.P. 168/110. Jan. 3rd, 1935: urine clear; very slight œdema; B.P. 154/108; urinary output good. As patient was at term castor oil and quinine given. Jan. 4th: labour pains began at 7 P.M.; urine clear at 8 P.M.; eclamptic seizure at 11 P.M., with B.P. 156/82 and a cloud of albumin in the urine. Jan. 5th, 11 A.M.: 14 fits to date; forceps delivery under local anæsthesia; child 7 lb. stillborn. Uninterrupted recovery; urine clear on the third day.

This case is a striking demonstration of the fact that raised blood pressure is one of the most reliable pre-eclamptic signs, and may be present long before there is any albumin in the urine. There was no albuminuria in this case three hours before the onset of eclampsia.

In conclusion, it would appear that strict antenatal care can reduce the incidence of eclampsia and also its severity; for when eclampsia develops, despite good antenatal care, it seems to take the

* The substance of this paper was read before the Glasgow Obstetrical Society on Jan. 22nd. 5867

form of seizures brought on by the stress of labour, with rapid recovery in the puerperium.

Albuminuria.—In 1162 patients treated in the antenatal wards for albuminuria during the first five-year period there were 40 deaths (3·4 per cent.), and in 1397 patients during the second period 22 deaths (1·5 per cent.). This includes the 8 deaths from eclampsia which occurred in the first five-year period, already dealt with above. The improvement in the death-rate in the second five years is not due to any striking advance in treatment but to earlier admission to hospital and earlier termination of the pregnancy with improved methods of induction of labour. During the first five years valuable time was frequently lost by attempting medical induction, which was often unsuccessful and necessitated the use of bougies which often had to be reinserted several times before labour began. Bougies are now seldom used and have been replaced by rupture of the membranes, which has many advantages. It induces labour more quickly, does not require a general anæsthetic, and is less liable to be followed by sepsis. Although surgical induction was practised 268 times in the second five years and only 130 times in the first, there were only 3 deaths from sepsis in the second period as compared with 10 in the first. Of these 13 deaths 8 occurred after the use of bougies and 1 after rupture of the membranes. The gross liver damage demonstrable histologically in many of those toxæmic cases emphasises the unsuitability of a general anæsthetic, and especially chloroform, which was the anæsthetic used for the insertion of bougies. In 10 of the 54 cases with fatal albuminuria, the obstetric history showed quite clearly that the patient was quite unfit for pregnancy, which should have been prevented.

Hyperemesis (vomiting in the early months of pregnancy).—The number of cases of hyperemesis admitted to hospital has increased from 255 in the first five-year period to 382 in the second, while the death-rate has fallen from 12·1 per cent. to 4·4 per cent. As with albuminuria, there has been no striking improvement in the method of treatment in hospital, and the improvement in the death-rate is due to earlier termination of the pregnancy by better methods. There should be almost no deaths from hyperemesis, and this could be achieved by earlier admission to hospital. In the second five years, 11 of the 17 deaths from hyperemesis were in patients so ill on admission that they died within four days. The improved technique for termination of pregnancy in cases of hyperemesis, reflected in the fall in the number of deaths from shock from 13 to 3, consists of the substitution of spinal anæsthesia or gas-and-oxygen for chloroform, and of abdominal hysterotomy in many cases for curettage, preceded by dilatation of the cervix by laminaria tents or forcibly with Hegar's dilators.

Toxic vomiting in the later months.—This category includes cases of toxæmia in the later months where there is no rise of blood pressure, œdema, or albuminuria, the chief symptom being vomiting. In the first five years there were 15 deaths, 10 occurring soon after admission in severely ill patients, and in the second five years 9 deaths, all soon after admission in severely ill patients. Apparently, therefore, the mortality could be reduced by earlier admission to hospital.

Pyelitis of pregnancy is included with the toxæmias for convenience. In the first five years there were 10 deaths and in the second five years 11. As microscopic examination of a catheter specimen of urine was not a routine practice in all patients admitted to the antenatal wards during the first five years, the exact number of cases of

pyelitis admitted during this period is unknown and the mortality-rates for the two five-year periods cannot be compared. As in the toxæmias already considered, earlier admission to hospital and better methods of terminating pregnancy would reduce the mortality.

SEPSIS

This heading covers all cases in which the patient died in another hospital after being transferred because of sepsis. It does not cover deaths from sepsis following the toxæmias and hæmorrhages of the later months, for these are dealt with in each separate group. The number of deaths from sepsis has fallen from 139 in the first five years to 98 in the second.

Sepsis following normal delivery.—There has been a striking fall in the number of deaths from sepsis after spontaneous delivery, for although over 1000 more normal cases were admitted to the hospital in the second five years, there were only 15 deaths as compared with 30 in the first. Those 15 deaths include 2 cases which were already infected on admission, delivery having occurred outside. The improvement is probably due to recognition of the fact that the commonest source of the hæmolytic streptococcus is the nasopharynx, the practical application of which includes the wearing of masks and the exclusion of all persons harbouring streptococci from contact with the patient during labour or the puerperium. For the second five-year period, the death-rate from sepsis following spontaneous delivery in the group under consideration is approximately 1·3 per 1000, which demonstrates that the risk of sepsis in hospital is no greater than elsewhere.

Sepsis following complicated delivery (excluding Caesarean section and "failed forceps outside").—The deaths from sepsis in this group have fallen from 42 in the first five years to 27 in the second. For the purpose of analysis cases have been divided into emergency and hospital cases, the latter including those admitted so early in labour that the hospital was really responsible for the conduct of the labour. The number of deaths in hospital cases remains the same, but there is a striking fall in the deaths in emergency cases, from 28 in the first five years to 13 in the second. The improvement in antenatal care has resulted in fewer cases being admitted as emergencies after prolonged labour and more before the onset of labour or in the early stages of labour. This is shown by the greater number of cases of contracted pelvis dealt with by the hospital (2335 in the second five years as compared with 1370 in the first) and by the greater number of forceps deliveries in hospital (1810 compared with 1260). The mortality in hospital cases has therefore diminished, since the number of deaths has remained the same in the two periods.

The results in this group show a great all-round improvement in the treatment of difficult labour, although there are still about 25 per cent. of these fatal cases which are probably avoidable. More than half of the rest of the fatal cases, which were probably unavoidable, were cases of uterine inertia, resulting in prolonged labour, repeated vaginal examination, and instrumental delivery. The fact that the cause of death in 4 cases was chloroform poisoning emphasises the unsuitability of this anæsthetic in cases of difficult labour.

Sepsis following "failed forceps outside."—The number of deaths from sepsis in this category has risen from 19 in the first five years to 22 in the second,

and the number of such cases admitted to hospital has risen from 190 to 236. The increase in this group is disquieting. In all the fatal cases the head was still high in the pelvis on admission, under which circumstances forceps delivery is rarely the correct procedure and is so difficult that it should be attempted only under the best conditions. Where there is a definite contracted pelvis in a primigravida, or a history of difficult delivery in a multipara, difficulty should be anticipated. Of the fatal cases, however, 9 were in multiparæ in whom the previous labours had been easy and where appreciation of the high position of the head in the pelvis was the only warning of probable difficulty. Hospital treatment can have very little influence on the mortality in this group.

Sepsis following Cæsarean section.—There were 424 Cæsarean sections performed for contracted pelvis in the first five years with 13 deaths from sepsis (3 per cent.), and 699 in the second five years with 14 deaths from sepsis (2 per cent.). The fact that the death-rate from sepsis after Cæsarean section has fallen from 3 to 2 per cent. is probably due to the more frequent use of the lower uterine segment operation in the second five years. In the first five years 410 classical Cæsarean sections were performed with 13 deaths (3 per cent.)—12 of which were due to generalised peritonitis—and 14 lower uterine segment sections with no deaths. In the second five years 449 classical Cæsarean sections were performed with 11 deaths (2·6 per cent.)—6 from generalised peritonitis—and 250 lower uterine segment operations with 3 deaths (1·2 per cent.), none from generalised peritonitis. This difference in the mortality from the two operations is all the more striking because a bigger proportion of the cases which had the lower uterine segment operation were "suspect"—i.e., cases where the risk of sepsis was greater because the patients had been many hours in labour. In the "suspect" cases in this group the notifiable pyrexia-rate was 18 per cent. in those who had the lower uterine segment operation and 45 per cent. in those who had the classical Cæsarean section. The risk of peritonitis is less after the lower uterine segment operation than after the classical Cæsarean section. The lower uterine segment operation might be employed more often in cases of minor disproportion, after unsuccessful trial labour, which in these cases may be the only means of deciding whether delivery from below is possible or not. It is certainly safer than the difficult forceps delivery or craniotomy which is the alternative in these cases.

Sepsis following manual removal of the placenta.—In the first five years there were 9 deaths from sepsis after manual removal of the placenta, 7 in hospital cases and 2 in patients delivered outside; and in the second five years 7 deaths, 3 in hospital cases and 4 in patients delivered outside. Numbers are too small to draw any conclusions.

Sepsis following abortion.—In the first five years there were 3290 cases of abortion admitted with 26 deaths (0·8 per cent.), and in the second five years 3219 cases with 11 deaths (0·3 per cent.). The reduction in the mortality-rate may be attributable to more strict enforcement of refusal to admit septic abortion cases. The only change in hospital technique is that packing of the vagina has been practically given up.

SHOCK

There were 58 deaths from shock in the first five years and 56 in the second. Deaths under anaesthesia have been included in this group for convenience.

Deaths under anaesthesia include 5 cases of delayed chloroform poisoning. In the fatal cases the operations were curettage for abortion (7), Cæsarean section for contracted pelvis (3), insertion of bougies (2), and forceps delivery after long labour (11), in 5 of which the cause of death was delayed chloroform poisoning. Chloroform was the anaesthetic in all cases except one, in which spinal anaesthesia was used.

The fact that delayed chloroform poisoning was the sole cause of death in 5 cases emphasises the danger of chloroform in obstetrics.

Deaths from shock, excluding those under anaesthesia.—In the first five years there were 48 fatal cases and in the second five years 42. There have been fewer deaths in emergency cases but just as many in hospital cases. As in the sepsis group, this is due to better antenatal care resulting in fewer cases of disproportion being admitted as emergencies and more being admitted before the onset of labour. But there is still room for improvement in antenatal care outside, for in the second five years 24 of the 42 fatal cases were emergencies. Of the other 18 which occurred in hospital cases death might have been avoided in several but was probably unavoidable in most.

Of the fatal cases in this group in the ten-year period 26 had rupture of the uterus, 4 in hospital cases and 22 in emergency cases. Eleven died undelivered. The average parity was seven, and there were only 2 primigravida. Of the 24 multiparæ 10 had had no previous difficulty. The increasing danger of rupture of the uterus with increasing parity should always be borne in mind, even where the labour is easy.

HÆMORRHAGE

In the first five years there were 104 deaths from antepartum and postpartum hæmorrhage and in the second five years 107. There is a diminished number of fatal cases of placenta prævia and an increased number of deaths from accidental hæmorrhage and postpartum hæmorrhage in the second five years.

Placenta prævia.—During the first five years there were 406 cases of placenta prævia with 53 deaths (13 per cent.), and during the second five years 487 cases with 37 deaths (7·5 per cent.). The immediate cause of death was hæmorrhage and shock in 56 and sepsis in 34. In 55 of the 90 fatal cases the patient arrived in good condition and in 12 she might have done so but for neglect of warning hæmorrhage. The fall in the death-rate in the second five years must be largely due to improved technique in hospital, but that this could be further improved is demonstrated by the fact that 22 of the 37 fatal cases in the second five years arrived in hospital in good condition. In many of those there was delay in emptying the uterus, either because the bleeding had ceased temporarily or the cervix was closed, making exact diagnosis difficult. One unit of the hospital has gradually in the last five years adopted the policy of emptying the uterus at once by Cæsarean section if the placenta is felt to reach down to within half an inch of or to cover the internal os, even although there may be no bleeding at the time. Blood transfusion is used extensively. During the second five-year period 174 cases of placenta prævia were admitted to this unit with 7 deaths (4 per cent.); and 3 of them were admitted moribund.

I see no reason why the death-rate from placenta prævia should be more than 3 per cent.—less than

half the present rate for the whole hospital. Some lives would be saved by earlier transfer to hospital on the first hæmorrhage. Most of the deaths would be avoided by improvement in hospital technique—that is, prompt emptying of the uterus after admission to hospital, the avoidance as far as possible of vaginal manipulation, and the extensive use of blood transfusion. This last has been employed far too little in the past: it was used in only 3 of the 56 fatal cases where hæmorrhage was the cause of death, and in only 7 of the 34 where sepsis was the cause of death. It should not be regarded as a desperate remedy but should be given as quickly as possible after the blood loss.

Accidental hæmorrhage.—During the first five years there were 527 cases with 24 deaths (4·5 per cent.) and in the second five years 633 cases with 32 deaths (5 per cent.). In 42 of the fatal cases the patient was so ill on admission that she died within a few hours. In 4 cases there was excessive bleeding, and the patient's life might have been saved by blood transfusion; but on the whole there seems little scope for improvement in the results of treatment along the usual lines. The question arises whether these catastrophes could be avoided by adequate antenatal care, since they are commonly believed to be the result of toxæmia; but an analysis of the more complete antenatal records of the second five years fails to show evidence of toxæmia in many of the cases. Even where there was toxæmia it was usually mild, hæmorrhage occurring suddenly without warning, so that antenatal care can do little in the prevention of accidental hæmorrhage. In 30 of the 56 fatal cases in the whole ten years the patient had had seven or more children, often in rapid succession. Better spacing of the children would probably diminish the risk of this complication.

Postpartum hæmorrhage.—During the first five years there were 16 deaths from postpartum hæmorrhage and 27 during the second period. Blood transfusion was given in only 2 of the 43 cases, although in 29 of these (14 hospital and 15 emergency cases) there was time available. Organisation of donors on a large scale should make it possible for these patients to have blood transfusion within a short time of the hæmorrhage.

Abortion.—In the first five years there were 3290 cases of abortion with 8 deaths from hæmorrhage (0·24 per cent.), and in the second five years 3219 cases with 10 deaths (0·31 per cent.). In 4 of the fatal cases the patient was moribund on admission, and in the remaining 14, although the patients did not die until after periods varying from several hours to several days after admission, blood transfusion was given in only 2. While the death-rate in this group is low, it could be further reduced by earlier admission to hospital and more frequent use of blood transfusion, which would also minimise the incidence of sepsis by improving the patient's resistance.

INTERCURRENT DISEASE

During the first five years there were 82 deaths from intercurrent disease and in the second five years 77. This group includes such conditions as pneumonia, tuberculosis, meningitis, cancer, and cardiac disease. Only the deaths from cardiac disease will be considered in detail.

In the first five years there were 345 cases of cardiac disease complicated by pregnancy with 36 deaths (10·4 per cent.), and in the second five years 606 cases with 39 deaths (6·4 per cent.). The reason for the fall in the death-rate is that women with severe cardiac disease are being admitted to hospital earlier and are being kept in hospital longer.

Here again, however, there is room for improvement, for in the last five years 27 patients were admitted very seriously ill and 8 of them died before the pregnancy could be terminated. The best mode of delivery varies with each case but is not the most important factor in deciding the outcome. The decision must be made early in pregnancy whether it is safe to allow the pregnancy to proceed. Where it is decided that the cardiac reserve is sufficient, the greatest care to preserve it should be taken by adequate rest in bed. In 15 of the fatal cases in the first five years, and 5 in the second, the cardiac lesion was so severe that pregnancy should have been prevented, preferably by sterilisation.

CONCLUSIONS

The maternal death-rate in the Glasgow Royal Maternity Hospital is falling—partly because of an all-round improvement in technique and partly because the more abnormal cases, which were formerly sent in as emergencies, are now being sent to hospital before labour or in the early stages of labour.

There is room for improvement both inside and outside the hospital. The chief faults inside the hospital are (1) the lack of proper organisation for immediate blood transfusion in cases of hæmorrhage, and (2) the fact that many urgent cases, which present most difficult obstetric problems, have to be dealt with by junior members of the staff because their seniors are non-resident. The faults outside the hospital are the lack of adequate antenatal supervision, particularly in the toxæmias, and unjustifiable attempts to perform major obstetric procedures under adverse conditions. The problem outside the hospital, however, is more difficult, owing to ignorance and lack of coöperation on the part of the patient. Moreover in Glasgow rickets in childhood (causing a high incidence of contracted pelvis), multiparity, poor housing, and poverty are all very important factors. As the class from which our hospital patients come cannot afford even a small fee to a family doctor, an extension of antenatal supervision by the local authority—possibly with compulsory notification of pregnancy—is urgently required. More hospital accommodation, especially for antenatal cases, is also a pressing need.

It is clear that in some 9 per cent. of the fatal cases pregnancy was a grave risk which the patient should not have been allowed to undertake. Sterilisation or contraception was indicated. Experience at the voluntary birth control clinic shows that most of the patients cannot pay the sum necessary for the purchase of contraceptive materials, and as there are no birth control clinics under the local authority in Glasgow, this matter deserves their immediate attention.

NEW HOSPITAL FOR MELKSHAM.—Plans for this hospital, to be erected with the Ludlow-Bruges legacy of £200,000, have been prepared. They provide for a cottage hospital with accommodation for about forty patients. The wards and the administrative block will be of one and two storeys respectively.

WALSALL GENERAL HOSPITAL.—Two members of the Hale family have promised to provide the money for a children's ward at this hospital. The present ward has room for 10 children only, and those above eight years old have to be accommodated in adult wards. The cost will be between £4000 and £5000.

CHRONIC CICATRISING ENTERITIS

A PHASE OF BENIGN NON-SPECIFIC GRANULOMA
OF THE SMALL INTESTINE

BY R. F. BARBOUR, M.A. Camb., M.B. Edin.,
M.R.C.P. Lond.

AND

A. B. STOKES, B.M. Oxon., M.R.C.P. Lond.

ASSISTANT MEDICAL OFFICERS, THE MAUDSLEY HOSPITAL,
LONDON

GRANULOMATA of the intestine were formerly considered neoplastic, but later a "specific" group was isolated, leaving a non-specific residuum. To begin with, the granulomata of the large bowel received attention, and it is only in the last ten years that similar lesions in the small intestine have been adequately investigated.

Before 1895 most circumscribed chronic lesions of the intestine appear to have been regarded as neoplastic, but in that year Senn⁶⁰ distinguished between infective granuloma and carcinoma, while in 1907 Moynihan⁶⁴ reported six cases in which the original diagnosis of malignant disease of the large bowel was replaced by that of granuloma of the intestine. Two years afterwards Braun⁹ gave a survey of the condition and explained so-called cured cases of malignant disease as benign granulomata that had undergone resolution. Proust, Robson,⁵⁷ and Lejars⁴⁶ reported similar lesions. In 1913 Dalziel²² described cases in which the small, as well as the large, intestine was involved, and in one of these two feet of jejunum was removed at operation for partial obstruction.

Tietze⁶³ reviewed the condition in 1920. In some cases the cause of the granuloma was held to be tuberculous infection or syphilis, but in the majority no definite cause could be found. The non-specific origin of the granulomata of the intestine was emphasised by Moschcowitz and Wilensky⁶³ in 1923, while Mock⁶¹ in 1931 concluded that the benign non-specific granulomata did in fact form a definite pathological entity. He described their possible aetiology and symptoms, and believed them to be similar to tumours occurring elsewhere in the body. Since that time, although specific granulomata (e.g., tuberculous,^{12 17 23 32}) of the intestine have been reported, there is an increased tendency to regard many as of non-specific origin.^{3 59}

The importance of the benign non-specific granulomata affecting the small intestine was brought out by Crohn, Ginzberg, and Oppenheimer.¹⁹ Among 52 cases of non-specific granuloma of the intestine these authors isolated 13 in which the terminal ileum was involved.³³ To this localised condition the name of regional ileitis was given, although in America it also became known as Crohn's disease. Following this work numerous cases of granuloma of the lower ileum were reported under such titles as Crohn's disease, regional ileitis,¹³ regional enteritis,¹¹ chronic cicatrising enteritis,^{5 21 24} and localised chronic ulcerative ileitis.⁷ In some of them parts of the small intestine other than the terminal ileum were involved and lesions were found in the jejunum and in the duodenum. This more widespread involvement of the small intestine led Crohn¹⁸ to enlarge and amend his original concept.

It is interesting to note that almost all the recorded cases of non-specific granuloma of the small intestine are in the American literature; only a few are to be found in British and continental journals. In 1933

Molesworth⁶² in this country reported a single case of granuloma of the intestine with stenosis of the ileocaecal valve and likened it to cases described by Mock. In 1934 Jackman⁴⁰ described two cases under the heading of localised hypertrophic enteritis, while Dickson Wright⁶⁸ demonstrated two cases of Crohn's disease at the Medical Society of London in January, 1935. Owing to the recent interest in this condition the following case is recorded.

CASE-HISTORY

The patient, a man of 63, was of good family antecedents, and for thirty years had lived abroad as a medical missionary. In 1927 he was not allowed to return to China because of poor health. This however did not prevent him from holding several medical appointments in this country, and at the time of the onset of illness he was engaged in private practice in London. From 1927 he had suffered from indigestion and from "chills" which were liable to lead to vomiting. He also complained of indefinite pains in the back and chest which were attributed to "rheumatism and lumbago." He was seen by several doctors but no definite diagnosis was made, and he found that by following a simple diet he was able to overcome any temporary discomfort. For one year he had been losing weight and had seemed to be in poorer health.

Previous Illnesses.—Paratyphoid in 1906; sunstroke in 1907; typhoid in 1923; septic finger with cellulitis and axillary abscess in 1926, with amoebic dysentery in the same year.

History of Present Illness.—Early in September, 1934, the patient took his annual holiday and returned home seemingly fit. On Sept. 27th he felt "queer" and was unable to attend to his practice. Next day he complained of acute abdominal discomfort, and he was admitted the same evening to a London general hospital. On admission his temperature was 99.4° F. The liver was said to be enlarged and coarse friction was heard over the liver in the sixth right intercostal space. In view of the history of amoebic dysentery a tentative diagnosis of amoebic hepatitis was made and emetine gr. ½ was given intramuscularly. Examination of the stools failed to show entamoebæ or cysts. On three evenings the temperature rose to 99.4° but at all other times it was subnormal. On the third day he became difficult to manage, demanding food in the middle of the night and insisting that he was quite well. He rapidly developed a delirious condition in which he tried to get into bed without taking off his shoes and trousers, and on the sixth day he discharged himself from hospital.

During the next fortnight he was staying with relatives, and in the first week his physical condition showed little change. He was placed on a light diet, and to begin with took his food well. There was an occasional rise of temperature but no record was kept. During the second week he developed a thrombosis of the right calf and was admitted to the Hospital for Tropical Diseases, London. On the previous night his temperature rose to 101.4°, and he is said to have been making rambling remarks. On admission he was noted as appearing dehydrated and toxic, and during his stay his diet had to be supplemented by intravenous glucose-saline. Physically his condition remained unchanged; he had neither diarrhoea nor vomiting, and there was a slight rise of temperature on only two occasions. His mental state showed variation: at times drowsy, he was also at times violent. Sometimes he would refuse food by day, only to eat it at night. As the patient's uncoöperative attitude was dominating the clinical picture he was transferred to the Maudsley Hospital on Nov. 13th.

The *physical examination* on admission showed a middle-aged man, cachectic, and dehydrated, with sunken eyes and prominent cheek-bones. He lay in bed with his eyes closed and took no evident interest in his surroundings. He appeared to understand what was said to him, but would only answer by a nod of the head or a shrug of the shoulders. He would sit up or lie down, but would not coöperate in the finer tests. His breath was offensive,

the tongue was dry-coated, and the teeth showed pyorrhœa. Examination of the abdomen was difficult owing to the patient's failure to relax; the upper abdomen was held more tensely than the lower, which could be palpated satisfactorily. The patient indicated that he had had pain in the right iliac fossa but that it was no longer present. There was no visible peristalsis; no tumour or masses were found. The liver and spleen were not enlarged, the kidneys could not be palpated. Borborygmi were noted; the patient was incontinent of fœces, no blood or slime was present. No abnormalities were detected in the respiratory, musculo-skeletal, and central nervous systems. The heart sounds were weak but no murmurs were detected. The vessels were not unduly thickened. Blood pressure 110/70. The patient had glandular hypospadias.

Progress in Hospital.—The mental state continued negativistic; he resisted attention, but did not help himself. He showed little interest in his surroundings, and he occasionally made remarks, but no natural conversation was ever possible. Shortly after admission tube-feeding was started, and had to be continued at intervals. The patient vomited most days, and was also doubly incontinent. The vomiting was of two kinds—one immediately after being tube-fed, the other two hours later. It was never offensive or projectile. At one time the vomiting was so constant that for three days nothing but intravenous glucose-saline was given, and even then the patient tried to remove the needles. During December the vomiting became less frequent and he was able to take convalescent diet, at a few meals even feeding himself. Throughout he remained stuporous, and he never complained of pain or tenderness. The physical condition showed little change except that he appeared to be losing ground. The systolic blood pressure dropped to 78—the diastolic could not be detected. Four days before his death his temperature rose, on one occasion to 99·8°, but no cause for this could be found. Finally on Feb. 2nd he died quietly in his sleep.

CLINICAL AND LABORATORY DATA

The following data include tests carried out both at the Hospital for Tropical Diseases and at the Maudsley Hospital.

Temperature: Sept. 27th, 28th, 29th, daily swing from 97·6–99·4° F. No definite records are available for the period Oct. 2nd–16th. Oct. 16th, 101°; 17th, 100°; 19th, 99°. Thereafter subnormal till Nov. 12th, when 99° was again recorded; it continued at an average of 97° till four days before his death when 99·8° was reported, but it fell again to 97°.

Pulse: The rate remained between 70–80 till December when it rose to an average of 100 and remained at that level with little variation till within a few days of his death.

Weight: Sept. 30th, 7 st. 4½ lb.; Nov. 11th, 6 st. 6 lb.; Jan. 29th, 5 st. 12 lb.

Laboratory tests: The blood counts showed a progressive anæmia: 4,200,000–3,230,000 red cells per c.mm.; hæmoglobin, 80–58 per cent. The white count on admission was 12,000; thereafter no count above 4000 was obtained. The polymorphonuclear leucocyte percentage remained about 70 per cent. No abnormal red or white cells were seen. Neither vomit nor gastric analysis showed abnormal findings. Free acid was present in the fasting juice.

Fœces: The patient was incontinent of fœces on most days, but had diarrhœa only twice. Examinations for blood and slime were always negative. Culture of the stools showed *B. coli*, enterococci; no organisms of the typhoid group or entamœbæ were detected. *Giardia lamblia* cysts were found on several occasions.

Urine: A trace of albumin was present.

Other examinations of the blood including blood culture; urea and cholesterol estimation; and Wasser-

mann, Kahn, and Van den Bergh tests all gave negative or normal findings. The sedimentation-rate was increased; the blood-serum agglutinated typhoid 1:250. A levulose-tolerance test and examination of the cerebrospinal fluid failed to show any abnormalities. Several of these examinations were repeated more than once. Radiography was unfortunately impossible owing to the patient's lack of coöperation and his poor physical state.

AUTOPSY

The body showed extreme emaciation, but apart from the glandular hypospadias, the external appearance was otherwise normal. There was no evidence of an abdominal operation having been performed.

On opening the abdomen the great omentum was seen to be firmly bound down to the right iliac fossa. There was a generalised early peritonitis, non-hæmorrhagic, with very little free fluid. There was surface glazing of the peritoneum, with lymph flaking more conspicuous in the neighbourhood of the lower ileum and other portions of the small intestine.

At varying points along its length the small intestine

FIG. 1.—Diagrammatic scheme of the small intestine from the pylorus to the ileocecal valve, showing 13 places of thickening and 7 of thinning. Scale 1 mm. = 1 inch.

showed evidence of an inflammatory process in its walls. There were thirteen such portions as shown diagrammatically in Fig. 1, varying in length from ½ in. to 2 in. These portions were widely separated, as seen inside the abdomen, and in their neighbourhood the peritonitis was most evident. The first as measured in the formalinised specimen was 21 in. from the pylorus, the last 4½ in. from the ileocecal valve. In the fresh state these portions showed a relatively sharply defined area of congestive lividity. The adjacent mesentery was thickened and congested, but the mesenteric lymph nodes were not enlarged. The vessels in the mesentery appeared normal. These portions felt firm and hard, and on opening the gut the lumen of the intestine in these parts was narrowed and the wall greatly thickened. The degree of constriction varied but in the narrowest part the lumen was 0·5 cm. in diameter, and the thickest wall measured 0·9 cm. The thickness was associated with the presence of fibrous tissue and was greatest on the mesenteric side (Fig. 2). The mucous membrane had lost its normal rugæ, was thickened, more congested, and more spongy. There were one or two areas of ulceration.

There were also lengths of intestine which were ballooned out, with very thin walls, and no rugæ. Seven such portions were present, bearing no constant relation to the constricted parts. Sometimes they preceded or followed a constricted part (Fig. 3); sometimes normal gut intervened. The diagram explains the relation.

The inflammatory process did not show the same degree of activity in each of the thirteen portions. The more active lesions were in the neighbourhood of the lower ileum, and there the peritonitis was most marked, and there the omentum was bound down. The large intestine appeared normal saving for a small area of doubtful thickening in the cæcum. The appendix was normal.

The liver was slightly smaller than normal and showed slight back-pressure effect. No evidence of amebic hepatitis or abscess was found. The biliary tract was normal. The spleen was a toxic spleen. The kidneys were small with thinned, ill-defined cortices and slightly granular surfaces. The other abdominal organs were normal. In the thorax the lungs showed terminal bilateral broncho-pneumonia. There was no evidence of active tubercle in the pleuræ, lungs, or mediastinum. There was gross atheroma of the descending aorta. The heart and brain were normal.

MICROSCOPICAL EXAMINATION

Transverse sections of the localised lesions of the small intestine showed variations corresponding to the situation of the lesion. In general those nearer the ileocecal valve

showed evidence of a more acute pathological process than those further removed.

In the parts of more acute reaction there was much congestion and oedema of all portions of the bowel wall, and in these parts the mesentery was also involved. The reaction was a fibroblastic reaction with an infiltration of polymorphonuclear leucocytes, round cells, and plasma cells. In parts the reaction had gone on to a definite laying-down of fibrous tissue. The mucous membrane showed ulceration, and the submucosa was much thickened by congestion and cellular infiltration (Fig. 4). There were in parts accumulations of polymorphonuclear leucocytes with formation of small abscesses. The lymphoid tissue was not hypertrophied. The muscle coats showed most markedly the laying down of fibrous tissue, but there was also an infiltration with leucocytes. This infiltration was most evident in the tissue plane between the longitudinal and circular muscle coats. The serosa showed thickening with fibrinous exudate in which leucocytes were enmeshed.

In the parts of less acute reaction there was more fibrosis and less leucocytic infiltration. The mucous membrane was more intact. The striking feature of these portions was the presence of giant cells of foreign-body type in the tissue plane between the longitudinal and circular muscle coats. These giant cells were numerous and were found only in this plane. They were in close relationship to ganglion cells of Auerbach's plexus which appeared to be particularly prominent in these sections (Fig. 5). The giant cells contained hard-looking crystalline bodies of variable shape and size. In their neighbourhood the round-cell infiltration was more intense.

Everywhere the reaction was attended by great thickening of the bowel wall, with encroachment on the lumen. There was no pathological evidence of tubercle. The sections appeared to be those of non-specific granulomata of the small intestine. Sections of the ballooned portion showed a marked attenuation but without inflammatory reaction.

Sections of the liver showed a good deal of fatty degeneration particularly affecting the portal zone, but without inflammatory reaction. In the kidneys there was chronic glomerulo-tubular nephritis with acute exacerbation.

DISCUSSION

Symptoms and Signs.—This case, although presenting the pathological features of chronic cicatrising

FIG. 2.—Photograph of a cross-section of the ileum showing thickening of its walls and mesentery.

enteritis, had an abnormal symptomatology owing to the patient's mental state.

Crohn¹⁹ divided his cases into four clinical types which have been adhered to by subsequent authors.

1. Acute intra-abdominal disease with peritoneal irritation.
2. Ulcerative enteritis.
3. Chronic obstruction of the small intestine.
4. Persistent intractable fistulae in the right lower quadrant.

Each of these types has its characteristic symptoms. In the first type acute appendicitis is simulated and

in this connexion it is noteworthy that appendectomy has been performed for the relief of symptoms^{25 56}; other cases of "acute abdomen" may represent the acute stage of this condition.^{39 40} In the second type the patient complains of colic and

FIG. 3.—Photograph of a portion of the ileum showing adjacent constricted and ballooned parts.

frequency of bowel movements, and there is usually a low-grade constant fever. In the third type incomplete obstruction is encountered with violent cramps, borborygmi, and occasional attacks of vomiting and constipation; a palpable mass may be felt³⁴ and the obstruction may be complete.² In the fourth type intractable fistulae follow the operative drainage of a supposed appendix abscess.^{30 42} It is probable that these types represent phases of one progressive lesion¹⁶ and that therefore an overlap in the symptomatology is to be expected.

The age-period is worthy of note. Crohn¹⁹ originally described the condition as chiefly affecting young adolescents, but cases have since been reported involving all age-groups, even the sixth and seventh decade.^{10 50} Our patient was aged 63. Rockey⁵⁸ reported four cases in children operated on for appendicitis of ages 5, 9, 11, and 19 in which there was a hypertrophy of the terminal ileum with mesenteric adenitis and in which tuberculosis seemed to be excluded. The possibility of a familial incidence has been suggested by Crohn,¹⁸ who records two cases in children of the same parents.

Diagnosis.—Almost all of the reported cases seem to belong to the third group described by Crohn and therefore have been reported under the heading of chronic cicatrising enteritis. The cicatrization does not usually give rise to a gross form of obstruction, and in the absence of a palpable mass the clinical picture is often indefinite and the diagnosis difficult¹⁰; in our case, complicated by a severe mental illness, the diagnosis was not made during life. In these circumstances the diagnosis is often one by exclusion but Galambos and Mittelman,³¹ Kantor,⁴¹ and Weber⁶⁴ have described X ray appearances which they believe to be typical and diagnostic when the terminal ileum is involved.

The differential diagnosis is usually from neoplasms, malignant and benign⁴³; the specific granulomata, including hyperplastic tuberculosis, lymphadenoma, actinomycosis, and syphilis; and the localised inflammatory masses associated with chronic infection of the appendix and Meckel's diverticulum.^{19 38}

Chronic intussusception¹⁰ and twisted ovarian pedicle²⁰ have been simulated.

Etiology.—Chronic cicatrising enteritis is not the result of any single aetiological factor. It is a particular clinical example of granuloma of the intestine

FIG. 4.—Low-power photomicrograph showing submucosa thickened with cellular infiltration and congestion.

of non-specific origin. It is believed that in every case an initial factor impairs the vitality of the gut wall and allows bacterial invasion from the lumen of the gut. The bacterial invaders are probably numerous in kind, but all produce a similar type of granulomatous reaction. In that sense all the lesions are non-specific.³

Mock classifies fully all the possible factors producing the local lessening of resistance which is followed by the production of these granulomata in the alimentary tract. Of these factors some are more or less theoretical, others more substantiated by the facts of the recorded cases. In the substantiated cases foreign bodies and infections appear to be outstanding. The former include fishbones, cherry pips, fruit cake, sponges in the abdomen, and particularly ligatures and sutures from a preceding operation. The latter include specific bacterial infection (e.g., bacillary dysentery), protozoal infections (e.g., amœbic dysentery), and metazoal infections (e.g., worms). Diverticulitis and ulcerative colitis sometimes precede a localised granuloma.

In the small intestine the foreign-body factor was at first thought to predominate; preceding operations were stressed in the case-histories and suture material was incriminated. More recently this factor has been found inadequate and suggestions have been made that mechanical factors operate either directly on the gut or on its blood-supply. Chronic recurrent self-reducing intussusception at the ileocecal valve, or an upset of local circulatory conditions by an appendicitis, might account for a terminal ileitis, but they would not account for lesions higher up in the intestine.

The case recorded here had a history of alimentary infection by *Entamoeba histolytica*, *B. typhosus*, *B. paratyphosus*, and *Giardia lamblia*. There was no evidence of foreign body and no abdominal operation had been performed. The other possible primary factors suggested by Mock and others,^{3 5 34 61} such as trauma, mechanical interference with the blood-supply, and extension of infection from extra-alimentary sources, were not found. The involvement of small intestine alone would appear to exclude

Entamoeba histolytica: the widespread involvement of the small intestine is against *B. typhosus* and *B. paratyphosus*. The giardia infection was present up to the time of death and giardia cysts were frequently and easily found in the stools. *G. lamblia* is a recognised invader of the small intestine,^{49 62} and attention has recently been directed to the widespread lesions caused by this organism in the small intestine by Little,⁴⁷ Lyon and Swalm,⁴⁸ and Paula e Silva.⁵⁵ In view of this work it is suggested that the giardia infection was the primary cause of the granulomata found in this case.

Pathology.—The pathological lesion in chronic cicatrising enteritis tends to be localised and may particularly affect the terminal ileum. Its localisation may be anywhere in the small intestine and a similar condition has been noted in the stomach.⁴⁵ The lesion may be multiple.

The lesion is a chronic inflammation of the wall of the gut with considerable stricture of the lumen. The inflammation involves the mesentery and the lymph glands may be enlarged.^{7 11 24} In the case reported no lymph nodes were involved. Ulceration of the mucous membrane may occur. Ballooning of portions of the gut has infrequently been observed.³⁸ It was present in this case.

Microscopically the lesions show a fibroblastic reaction with infiltration of polymorphonuclear leucocytes, round cells, and plasma cells.^{14 15 24 26 33 35 37} The inflammation involves all layers of the wall and is attended by fibrosis. Giant cells have been recorded,^{10 11 15 16 19 24 34 39} sometimes incorporating hard crystalline bodies of variable shape and indeterminate origin,^{6 26 33 53 65 66} although regarded by some as of lipid nature.³⁹ Their restriction to the intermuscular plane and juxtaposition to Auerbach's plexus is an outstanding feature of this present case. It is suggested that the involvement of Auerbach's

FIG. 5.—High-power photomicrograph showing the intermuscular plane. Giant cells with crystalline bodies are seen adjacent to Auerbach's nerve ganglion.

plexus by the inflammatory process accounts for the ballooning of portions of the gut.

The lesions do not appear to have any anatomical arrangement and show none of the features of tuberculosis.^{37 63} Hyperplastic tuberculous lesions of the ileum are rare and it is probable that some of the reported cases are really non-specific granulomata.^{53 65} In the present case the lesions reach as high as the

upper jejunum and a primary tuberculous lesion in this situation would be extremely rare.

The occurrence of metaplasia in the epithelium of the inflamed gut has been suggested by Donchess and Warren,²⁴ and a possibility of early carcinomatous change. This would be a further example of malignant change occurring at a focus of chronic infection.²⁷

Treatment.—Treatment at present consists of excision of the affected areas,^{11 26 34 35 38} with or without a short-circuiting operation. The fact that so many of the reported cases had been operated on previously for appendicitis^{15 18 19 21 33 39 53 66} seems to indicate the advisability of exploring the terminal and lower ileum in all cases of chronic appendicitis that come to operation.

SUMMARY

(1) A short historical survey of granulomata of the intestine is given, with special reference to a group involving the small intestine, isolated by Crohn. (2) The present case is one of chronic cicatrising enteritis and its symptomatology is discussed with reference to four clinical types. (3) Diagnosis is usually by exclusion. Typical X ray appearances have been described when the terminal ileum is involved. (4) Aetiologicaly many primary factors may operate, all producing an infective granuloma of non-specific type. It is suggested that the giardia infection was the primary factor in the present case. (5) Pathologically strictures and dilatations of the gut are met with. Microscopically giant cells incorporating foreign bodies of indeterminate origin are seen in a picture of chronic inflammation. In the present case they are in juxtaposition to the nerve-cells of Auerbach's plexus. (6) Treatment consists in excision of the affected parts.

Thanks are due to Dr. Edward Maphother for permission to publish this case; to Dr. P. H. Manson-Bahr and Dr. E. ff. Creed for their valuable help; and to Mr. Geary for preparing the specimens. The photographs were obtained by the aid of Dr. H. A. Ash. We are responsible for the opinions offered.
